SIR,—Mr. Howatson's letter in your issue of March 25th on this subject is another illustration of the all-absorbing interest which is taken in the subject of sewage purification. It is interesting to observe that independent experiments are being conducted by so many workers at the same time, and your readers will welcome the publication of the details and results of his systen.

There are some points raised in his letter which are, however, open to considerable controversy. For instance, we are assured in paragraph 3 that "chemical treatment for sewage purification can be applied in every case, and if properly carried out no system can cope with it as to results obtained." May I ask if Mr. Howatson will oblige your readers with any single instance where sewage is purified efficiently by chemical treatment? No English engineer, I fancy, would acquiesce in the reliability of such a statement, for the failure of the chemical treatment *per se* to efficiently purify sewage to meet the requirements of the County Council is generally acknowledged to be beyond dispute.

"The only bugbear is the sludge." Mark the word ONLY in capital letters, please. Mr. Howatson, like so many enthusiastic patentees who have preceded him, is going to prove, he tells us, that sludge can be made a marketable article, and be sold at a price in any case sufficient to cover all the working expenses of the sewage treatment.

One sincerely hopes that he will do so; but I might suggest, it would be prudent of him in proposing this scheme that he does not stake his reputation and also his purse, as he tells us engineers have to do in proposing any scheme in France.

Concerning his proposal to heat the air around and over sewage filters, let me remind him that this is a method already adopted by Colonel Ducat for his filter at Hendon. It is doubtless good in theory, but in practice is open to much objection, and would break down in working. Imagine what would be required to heat the filters for towns such as Manchester or Leeds with twenty or thirty acres of bacteria filters!

No. If bacteria filters require treating as invalids, it would be well to commence, in orthodox fashion, with a proper diet, and give the bacteria a supply of blankets and beef tea. The suggestion of applying heat is out of the question, and we had better devote our energies to experiments likely to be more productive of good.

It has yet to be proved that bacteria filters fail to act efficiently in winter. What is required to be known is what kind of material and what method of construction as applied to them is likely to produce the best results. That system will, it may safely be predicted, find most favour which is devoid of artificial aids and of machinery.—Yours faithfully, ENGINEER.

LONDON DRAINS.

SIR,—On all sides one hears of the great amount of measles and other illnesses about. I refer to London. I think I can give a reason, and that is, that in London our drains are insufficiently and ineffectually flushed. Probably a good storm of rain or two would give these a good cleansing; but how long its beneficial effect would remain is another question.

At present our sewers are not flushed on the top, and only partially on the sides, while the force of water is insufficient to wash off the accumulations which render them dangerous to health. This washing can be done thoroughly by using but one-tenth of the water now recklessly poured down our drains (without flushing force).

There is only one way to do it, and the sooner the Local Authorities take it to heart the better. A valued and skilled surveyor—I refer to the late Mr. Walker, of St. Martin's parish—I believe stated this repeatedly:—"The most efficient flushing is by either a fixed or temporary pipe placed in the sewers and connected to the street water force, thus washing with such power that every part of the drain is effectually cleansed." Mr. Walker's opinion was that the dry and unwashed upper parts of the drains were more disease-spreading than any other.

If one wants to put out a fire in a building, one would not pour water on the floor, but would attack the burning mass with jets of water. Drain fever germs want the same treatment. When this is given, and not till then, will be cut away the root of disease germs so freely spread in the atmosphere through vent-holes and ventilators.

Many borough and district surveyors would be glad to see more efficient means of drain flushing

provided, and many Local Authorities would like to expend funds in the adoption of the new system, but public opinion requires to be educated in the matter.—Yours faithfully,

J. C. MERRYWEATHER.

Greenwich-road, S.E., March 24th.

NOTE.—A letter from Mr. C. Chambers Smith, in reply to Messrs. Cameron, Commin, and Marten, is unavoidably held over until our next issue.—ED. S. R.

Law Cases.

A SANITARY AUTHORITY FINED.

THE Farnborough Urban Council were summoned at Aldershot by Messrs. Hannah Dever, Colonel Antonio S. Ralli, Lieut.-Colonel Watson, and Major Hippisley, for neglecting their duty as a Sanitary Authority. The case for the prosecution was that having undertaken the duty of cleansing cesspits in part of their district, they were liable to a penalty of 5s. a day in each case of neglect to do so.

The Bench found that the Council had failed to carry out their undertaking, and in one case inflicted penalties and costs amounting to £5.

IMPORTANT TO LOCAL AUTHORITIES.

THE case of Harrop and others *v.* the Mayor and Corporation of Ossett was a *quia timet* action based on private nuisance. The plaintiffs, who were the trustees of an estate and also the owners of a shoddy warehouse and factory, claimed an injunction restraining the defendants from using a hospital as a small-pox hospital. The hospital was a small one, having room for some eight patients. As yet only one small-pox patient had been received there. The hospital was some 250 yards distant from a valuable mansion belonging to the plaintiffs, 100 yards from the privies of the factory and about the same distance from the warehouse, and about 170 from a dwelling-house, occupied by its owner. A 6ft. wall enclosing an open space of 40ft. surrounded the hospital. The plaintiffs raised no objection to the hospital being used for infectious or contagious diseases other than small-pox. Their principal contention was that any small-pox hospital must be necessarily a source of danger to persons in its neighbourhood, because that disease was disseminated, *inter alia*, by air-borne infection or what was called aërial convection. Numerous members of the medical profession were called, who stated their views on this much-vexed question. The medical officers of Sheffield, Leicester, and Bradford stated that they had become converts to the theory from their actual experience. The plaintiffs, in their reply, submitted that whether the theory of aërial convection was sound or not, the evidence showed that a small-pox hospital was in fact undoubtedly a source of danger to its neighbourhood.

Mr. Macmorran, Q.C., and Mr. O. Leigh Clare, appeared for the plaintiffs; and Mr. Cozens-Hardy, Q.C., and Mr. J. G. Wood for the defendants.

Mr. JUSTICE ROMER said that the principles applicable to claims for relief in *quia timet* actions were well known. In order to sustain such an action the plaintiffs must establish a strongly or extremely probable case that the apprehended mischief must arise. The evidence here was most conflicting, and he did not intend to weigh one side against the other. He could only say that, to his mind, the short result was that the plaintiffs had not established a case entitling them to an injunction. He should give no opinion about the point about which the experts differed so much—namely, the aërial convection of small-pox. All that he should say was that on the balance of testimony a small-pox hospital might be a source of danger if badly conducted, and further he thought that where a small-pox hospital was established there was a tendency for cases to arise in its immediate neighbourhood, especially when the hospital was large and its neighbourhood crowded and ill-ventilated. But he was not satisfied that when such a hospital was well conducted it was such a substantial source of danger as to constitute it a legal nuisance, and it was certainly not so when the hospital was one like the present—a small one. Taking into consideration the small size of this hospital, its situation, and general nature, he was not satisfied that it would be such a substantial source of danger as would justify the granting of an injunction. Moreover, for several years previously there had actually been a small-pox hospital in the immediate neighbourhood, and no ill result had ever flowed from it, either to the plaintiffs or others. It was said that the hospital might prove a source of danger when the plaintiffs' land was built upon. It was not necessary to deal with that until the case arose. He was satisfied that, to persons using the land in its present state, there was no substantial source of danger. He also thought there was no source of danger from drainage. All the witnesses, moreover, agreed that vaccination offered complete protection, and he thought that the Court should consider that by taking such reasonable precautions the plaintiffs and others in the neighbourhood could protect themselves. The case, moreover, was not one of public nuisance but of private nuisance. He therefore dismissed the action with costs.

The defendants asked for an order for solicitor and client costs under the Public Authorities Protection Act, 1893.

His LORDSHIP, after a full argument, held that under the Act he had no discretion, and that the defendants were entitled to solicitor and client costs, and made an order accordingly.

THE question of the reasonableness of a bye-law made by the Kent County Council as to singing or playing of instruments in the streets within fifty yards of occupied houses, was again before the Law Courts on Tuesday. The Judges, the Lord Chief Justice and Mr. Justice Mathew differed, the former holding the bye-law to be good, and the other declaring it to be *ultra vires*. The conviction in one case accordingly formally stands; but it was resolved, owing to the divergence of views, and as there was no appeal, that a second case should stand over and be argued before five Judges.

Notes and Queries.

Subscribers have the privilege of obtaining advice in this column on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed to THE EDITOR, "Notes and Queries," THE SANITARY RECORD, 5, Fetter-lane, London, E.C.

NOTE.—If an answer be required immediately, a stamped addressed envelope must be enclosed, when we will endeavour to furnish a copy of the answer by post, as owing to the large number of queries received we cannot guarantee the insertion of a reply in the succeeding issue.

1009.—GULLY TRAPS AND DISHES: SOIL PIPES: SUGGESTED IMPROVEMENTS.—"H. S. H." writes:—"I enclose sketches showing (1) air-tight lid, with slot and screw fastening, to be fixed in a vertical soil pipe, immediately above the junction of soil pipe, with vertical shaft, so as to save the trouble of getting to the top of a very high shaft when applying the smoke test; (2) a gully with detachable dish, so that the gully can be turned in any direction to meet the drain, while the top can remain square against the wall. This dish, left open on one side—*i.e.*, without rim—can be made up with brickwork to get the necessary 18in. from the waste pipe to the gully. I also show an inspection cap on the last pipe of the drain, adjacent to gully, for cleaning out the last joint. What I wish to know is, the names of makers of such appliances; or, if they are not manufactured, could you reproduce the sketches, so as to open the eyes of some makers to the necessity of manufacturing such? I also find a difficulty in getting builders to use syphons with necessary fall in themselves. Many makers pay no attention to this."

Answer.—Our correspondent is to be complimented on the conception of the ideas which he has put in concrete form to us. The improvements to the gully trap and dish have, however, been anticipated by makers for a considerable period, and may be obtained from the following firms, viz.:—The Albion Clay Company, Limited, 18, New Bridge-street, London, E.C.; Bugler and Co., Alpha Works, Putney, S.W.; Sankey and Son, Canning Town, London, E.; J. Place and Sons, Limited, Darwen, Lancashire; Young and Marten, Caledonian Works, Stratford, London; G. Skey and Co., Limited, Tamworth; Shanks and Co., Tubal Works, Barrhead, near Glasgow; Twyfords, Limited, Cliffe Vale Potteries, Hanley; Doulton and Co., Limited, Lambeth, London; Leeds Fireclay Company, 20, Park-row, Leeds. It would be inadvisable to plug the ventilating soil pipe immediately above the junction of the water-closet, even when there is a considerable length of shaft above such junction without another connection, as the purpose of the smoke test is to discover whether there are any bad joints in the drain and soil pipe below the roof. The consequence of blocking the soil pipe immediately above the water-closet junction would therefore be improper and constitute an imperfect test. There should be no difficulty in obtaining syphons which require a fall between the inlet and outlet. Any of the firms named will be able to supply such.

1010.—BUILDING BYE-LAWS: MODE OF CARRYING JOISTS IN WALLS.—"S. M." writes:—"Would you please give sketch showing method of carrying trimmer joists, floor joists, skirting boards, and purlins, to comply with the requirements of the Model Bye-laws Nos. 31 and 32, the former of which prohibits any timber being fixed in party walls, and the latter prohibits any joist being placed nearer than 4½in. from the centre line of a party wall?"

Answer.—The object of these two clauses, Nos. 31 and 32, of the Model Bye-laws as to New Buildings is to prohibit the insertion of all unnecessary timber and woodwork in party walls, and thus prevent the spread of fire from house to house. Hoop iron is recommended as an excellent substitute for bond timber, and can be used where requisite in a party wall, either for bonding purposes or instead of a wood plate. A double tier of hoop iron makes an excellent hold for the nails used in fixing wood grounds for skirtings and other woodwork, as wooden plugs, &c., are prohibited in party walls. Inasmuch as under Clause 32 joists may not be placed nearer to the centre of a 9in. wall than 4½in., it follows that joists, beams, &c., cannot properly be inserted in such a wall. Under these circumstances joists should be laid parallel with the party wall, their ends resting on the external front and rear walls, or on some internal wall of the building, and such trimming joists and other timbers as must be laid at a right angle to the party wall should be laid on a proper corbel, or on a wood plate resting on two or three courses of brickwork properly corbelled out, or on suitable iron brackets built into the walls.

1011.—INSUFFICIENT SEWERS: COMPLAINT AS TO. "W. M." writes:—"Some twenty years ago A sold four blocks of land, as per rough sketch [not reproduced], and allowed the main drains therefrom to discharge on the fields belonging to him, and lying near thereto. A now complains to the Sanitary Authority of the damage resulting from the sewage as applied to his fields, and requests the Sanitary Authority to provide sewers and dispose of the sewage. Can he do so?"

Answer.—Unless it can be shown that the sewage as at present discharged is a nuisance or injurious to health to the occupants of the houses, the Sanitary Authority may disregard his complaint. A's only remedy is to make complaint under Sec. 299 of the Public Health Act, 1875, to the Local Government Board; but unless it can be shown that injury to health is liable to be caused by the continuance of the existing system, the Board will most probably not interfere. It appears to us that the owners of the houses have acquired an easement for the drains in A's property.

1012.—SANITARY INSTITUTE EXAMS: FEES CHARGED.—"T. G." writes:—"Would you please inform me what fee is charged to candidates by the Sanitary Institute for the examination for Sanitary Inspectors?"

Answer.—The fee payable for the examination for Sanitary Inspectors (and also for the examination in Practical Sanitary Science), when the examination is held in London, is £3 3s., but when the examination is held in a provincial town £1 1s. extra (or a total fee of £4 4s.) is charged to the candidate in order to cover the expenses incurred in holding an examination out of London.

1013.—MILK: TAKING SAMPLES FOR ANALYSIS.—"P. K. S." writes:—"In taking samples of milk for analysis, must it be purchased in all cases and be divided into three parts?"

Answer.—We are of opinion that it is necessary under the Sale of Food and Drugs Acts, 1875 and 1879, when obtaining samples of milk under Secs. 13 or 14 of the former Act, and Sec. 3 of the later Act, that a public officer, or his assistant agent or deputy, must purchase such samples. The purchaser is also required under Section 14 of the Act of 1875 to forthwith, after purchase, notify to the seller or his agent selling the article his intention to have the same analysed by the public analyst, and shall offer to divide the article into three parts, to be then and there separated, and each part to be marked and sealed or fastened up in such a manner as its nature will permit, and shall if required to do so proceed accordingly, and shall deliver one of the parts to the seller or his agent. He shall afterwards retain one of the said parts for future comparison, and submit the third part, if he deems it right to have the article analysed, to the analyst. If the offer to divide into three parts is not accepted, the analyst, as provided by Sec. 15, is required to divide the article into two parts, one for analysis and the other to be returned to the purchaser. If the procedure be taken under Sec. 3 of the Sale of Food and Drugs Amendment Act, 1879, it will

not be necessary to announce to the seller his intention of having it analysed, nor to offer to divide it into three parts. Inspectors under the Acts should obtain Bell and Scrivener's "Sale of Food and Drugs Acts," price 4s. 6d., and procurable from the Sanitary Publishing Company. It should not be overlooked that an Inspector of Nuisances may seize milk exposed or deposited in any place for sale under Sec. 116 of the Public Health Act, 1875, if such milk is intended for the food of man, and if it appear to be unwholesome or unfit for the food of man, he may carry away the same to have it dealt with and condemned by a justice.

1014.—MEASLES: TRANSMISSIBILITY OF THE DISEASE.—"Measles" writes:—"Will you please refer me to any reliable information to the effect that the contagion of measles can be retained by bedding, clothing, carpets, walls, floors, or any other thing capable of being raised to the temperature of 212 deg. Fah., or limewashed or similarly treated?"

Answer.—It is generally acknowledged that the bacteriology of measles has not yet been systematically investigated, and it is rather from analogy than from experiment that it may be considered to be dependent on the specific microbe. The *materies morbi* is in the expectoration and in the cutaneous *débris*. It does not appear to be known whether the other excreta are infectious. We know of no experiments which have been conducted to test the transmissibility of measles by clothing, bedding, &c. It does not appear, however, to be transmitted by drinking water, milk, or other food. Our correspondent will probably find the paper read by Dr. Kenwood on "The Notification of Measles," which appeared in the *Sanitary Institute Journal* for July, 1897, useful, as well as the controversial papers on the same subject which appeared in THE SANITARY RECORD in the volume January to July, 1897.

1015.—MARGARINE ACT, 1887: SAMPLE NEED NOT BE PURCHASED.—"S. P." writes:—"Under Sec. 10 Margarine Act, must the sample of butter or article not marked margarine be divided into three parts, and can it be taken without paying for it?"

Answer.—Yes. Sec. 10 of the Margarine Act, 1887, provides that any officer authorised to take samples under the Sale of Food and Drugs Act, 1875, may *without going through the form of purchase provided by that Act*, but otherwise acting in all respects in accordance with the provisions of the said Act as to dealing with samples, take for the purposes of analysis samples of any butter or substances purporting to be butter which are exposed for sale and are not marked margarine as provided by this Act, and any such substance not being so marked shall be presumed to be exposed for sale as butter. The purchaser must offer to divide the sample into three parts, and immediately after purchase notify to the seller his intention of having it analysed by the public analyst.

1016.—SHOP HOURS ACT INSPECTORS: QUALIFICATIONS.—"T. H." writes:—"I should esteem it a favour if you could give me an idea as to what the qualifications are for the post of 'Shop Hours Act Inspector.'"

Answer.—Candidates for such an office, are usually required to produce some evidence of their sanitary knowledge and of an acquaintance with the Public Health Acts, which evidence has to be substantiated by the possession of the Certificate of Inspector of Nuisances from the Sanitary Institute. We are not aware that any other special qualifications are required.

1017.—HOUSING OF THE WORKING CLASSES ACT, 1890: URBAN AUTHORITY MAY ERECT COTTAGES FOR THE WORKING CLASSES.—"W. H. C." writes:—"A member of my Council has given notice of motion for the erection by the Council of workmen's cottages. Will you kindly inform me what powers an Urban Authority have to do this? Under the Housing of the Working Classes Act it would be necessary for the Medical Officer of Health to condemn an unhealthy area before the Council would have power to build, and in our case this could not be done. Therefore, if there is no other Act but the above, I take it that the Council cannot move in the matter."

Answer.—If the Urban Authority pass a resolution formally adopting (if they have not already done so) Part 3 of the Housing of the Working Classes Act, 1890, they will be enabled, under Sec. 59 of the Act, to "erect, on any land acquired or appropriated by them, any buildings suitable for lodging-houses for the working classes, and convert any buildings into lodging-houses for the working-classes, and may alter, enlarge, repair, and improve the same respectively, and fit up, furnish, and supply the same respectively with all requisite furniture, fittings, and conveniences." It may be observed that the expression "lodging-houses for the working classes" includes, as defined by Sec. 53, separate houses or cottages for the working classes, whether containing one or several tenements, and the purposes of the third part of the Act are to include the provision of such houses and cottages. Our correspondent is therefore in error in his interpretation of the provisions of the Act.

1018.—WORKSHOP INSPECTORS: DUTIES OF.—"Subscriber" writes:—"Will you kindly enumerate the duties of an Inspector of Workships, &c., under a Sanitary Authority, and under what Acts he will perform such duties? Any other information will oblige."

Answer.—We have not space to enumerate the duties of a Workshop or Shop Hours Inspector in this column. Our correspondent is, however, recommended to procure "Notes on the Factory and Workshop Acts, 1878, 1891, and 1895," price 4d., post free, from the Sanitary Publishing Company, wherein he will find in a concise form, arranged by Dr. Davies, an abstract of "Sanitary Provisions to be Administered by the Medical Officer of Health's Department." From this he will be able to obtain a general idea of the supervision which an Inspector of a Sanitary Authority has to exercise over such buildings. If he requires a full copy of the Acts, with annotations, he should procure "Redgrave's Factory Acts," price 6s., obtainable from the Sanitary Publishing Company. We may point out that the appointment of Inspectors under the Shop Hours Acts is entrusted by Sec. 8 of the Shop Hours Act, 1892, to the Council of any county or borough, and in the City of London to the Common Council.

1019.—COMBINED DRAINAGE: DRAIN OR SEWER.—"A. M. H." writes:—"What powers have an Urban Sanitary Authority to deal with the reconstruction of combined drains, as in the two following cases, viz., (1) where eleven houses, all belonging to different owners, drain into a common drain in a private passage; (2) where two houses drain into a common drain, which before entering upon the public road passes through a private garden? The two houses belong to one owner. Sketches submitted herewith.

Answer.—The sketches submitted are not so clear as is necessary. We are not able to gather whether the houses are within the same curtilage. Assuming, however, that they are, and, further, that the Public Health Acts Amendment Act, 1890, has been adopted in the district, and that the combined drain is on private premises, notice may be served on the owners to carry out any works which may be necessary thereto to abate a nuisance arising therefrom. The three leading cases upon the subject as to what is (1) a drain, and (2) a sewer, are (*a*) Vestry of St. Martin's-in-the-Fields *v.* Bird (60 J.P., 52), where it was decided that buildings forming an arcade, and described as the Lowther Arcade, were not premises within the same curtilage, but that each shop was a separate building and had its own curtilage, and that the drain common to all the buildings was a sewer;

and (*b*) Pilbrow *v.* Vestry of St. Leonard, Shoreditch (59 J.P., 68), where two blocks of buildings, let as forty-six tenements, were separated from each other by a narrow causeway or yard, to which the occupants of both buildings had access, but it was not a thoroughfare. It was held that the two blocks of buildings were for the purposes of the section "one building," and that they were within the same curtilage, and the combined drain was not a sewer for which the Authority were liable for repairing. (*c*) Seal *v.* Merthyr Tydfil Urban District Council (66 J.P., 55), where at the back of one side of a new street a drain was made, commencing at one end of the street, and running at the back of the houses through the gardens until it reached the public sewer. The houses belonged to different owners, and each house was connected with this drain, which was a drain for those particular houses, and for no other premises, and was not a general drain into which any houses could be drained. Held that the drain—being a drain constructed on private ground to which the public had no access—was a single private drain within Sec. 19 of the Public Health Act, 1890, and that the owners were liable to abate nuisances in such drain. In (2) we think that if the houses are in the same curtilage, or that the conditions are similar to those in Seal *v.* Merthyr Tydfil Council, the owner will be liable to abate any nuisance arising from the drain. In both cases notices should be served under Sec. 19 of the Act of 1890.

1020.—Sanitary Inspectorships: Qualifications.—"J. O." writes:—"(1) Do the public bodies who appoint Inspectors of Nuisances impose on candidates any restrictions as to height, age, and previous occupation? (2) My age is twenty-nine. Could I, if I gained the certificate of a Sanitary Institute, be eligible as a candidate for a Sanitary Inspectorship at a salary of £120 a year, provided that my health, character, and testimonials were satisfactory? Or must a man depend on 'influence' if he is to get a good appointment?"

Answer.—(1) Local Authorities usually stipulate that candidates for Sanitary Inspectorships must not be over forty or forty-five years of age. A person under twenty-one years of age would not be approved by the Local Government Board. There is no restriction as to height, nor as to previous occupation, although a candidate who is unable to show by his previous occupation that he has a practical knowledge of the work which he may have to superintend on becoming an Inspector, will not have such a favourable chance of being selected as those who are acting Inspectors or are practically acquainted with the building trade in some one or other of its branches. (2) Our correspondent would be eligible as a candidate, but it would be extremely doubtful whether, without having any practical experience, he would ever be selected to fill a position at a commencing salary of £120. He might obtain a position as Assistant Inspector at a lower salary, and ultimately, if he became a capable officer, obtain a position at a higher salary. There is always a plethora of candidates for any vacancy for an Inspector of Nuisances. A candidate must not depend on influence alone securing him an appointment. It is, no doubt, of great assistance, but he must be able to produce strong evidence of his fitness and qualification for the post.

1021.—Sewer or Drain: What is a?—"E. M." writes:—"An owner has been served with notice to reconstruct a drain which receives the drainage of two houses. I have advised him that it is the duty of the Sanitary Authority to repair all sewers, and under the Public Health Act, 1875, the drain in question would be a sewer in my opinion. Is not this so? Would it be worth while the owner contesting the matter with the Sanitary Authority to secure the reconstruction of the sewer or drain by the Sanitary Authority? I may add that both houses belong to the same owner."

Answer.—The decisions on the point as to what is a drain and what is a sewer are very conflicting. We are, moreover, not informed whether the district is under the Metropolis Management Acts, on under the Public Health Act, 1875. Briefly a "drain" means any drain of and used for the drainage of one building only or premises within the same curtilage, and a "sewer" is a drain receiving the drainage of two or more houses which are not within the same curtilage. If the houses are not within the same curtilage in this instance the owner might inform the Local Authority that the duty of relaying the drain is a duty which belongs to them, inasmuch as it is a sewer.

1022.—Crown Property: Duchy of Lancaster: Nuisances: Powers of Local Authority.—"A. J. M." writes:—"Will you please inform me whether the provisions of the Public Health Act, 1875, in respect to the drainage of existing buildings and abatement of nuisances apply to premises belonging to the Duchy of Lancaster, and can be enforced against them, the same as to those belonging to private individuals, or whether they are exempt?"

Answer.—Crown property such as that referred to is not specially exempted from the operation of the Act. Assuming however, that the property is in the occupation of the Crown, no compulsion by virtue of the Act can be put upon the Crown as occupier or owner. The provisions of Sec. 327, Sub-sec. 2, of the Public Health Act, 1875, as to exemption of Admiralty property and War-office property, must not be overlooked. According to the general rule of construction, the Crown is not bound by the statute, except so far as it is expressed to be so. But this rule, however, does not extend to exempting all Crown property from the operation of the Act. As we have already pointed out, if the property is in the occupation of the Crown, the Sanitary Authority

CAMPHYLENE CREAM

(unlike most Fluid Disinfectants) possesses a most refreshing and agreeable odour, yet thoroughly effective.

Unequalled for use in Hotels, Clubs, Public Conveniences, for Flushing Drains, Sewers, &c. &c. Supplied to a large number of Corporations, County Councils, and other bodies throughout the United Kingdom. 3s. 6d. per Gall. in 5 or 10 Gallon drums. Samples and special quotations for quantities on application.

Fleming's Oil and Chemical Co., Ld.,

101, Leadenhall St., London, E.C.

cannot interfere. On the other hand, if it is not in such occupation, the Authority may proceed in the ordinary manner.

1023.—COMMON LODGING-HOUSES: BYE-LAWS TO BE MADE BY LOCAL AUTHORITY.—"J. S." writes:—"Will you please inform me whether a Local Authority have power to make regulations for common lodging-houses without adopting the Model Bye-laws for all purposes? As I read Sec. 80 of the Act of 1875 I have the impression that the Council have power to make regulations."

Answer.—A Local Authority are not enabled to make regulations in respect to common lodging-houses but they are required to make bye-laws, the duty being compulsory, not optional, and a neglect to do so is a default to enforce the provisions of the Public Health Act, 1875. Model Bye-laws as to common lodging-houses have been issued by the Local Government Board, and copies may be obtained from them or from Messrs. Knight and Co., 90, Fleet-street, E.C. The Local Government Board do not permit much variation from the Model Bye-laws issued by them. In framing new bye-laws considerable assistance will be obtained from Knight's "Annotated Edition of Model Bye-laws," price 12s. 6d., which should be procured.

Vacancies.

BUILDING INSPECTOR (LITHERLAND, LANCS, April 16th).—For the Urban District Council. Salary £110 per annum. Messrs. North, Kirk, and Cornett, clerks to the Council, 15, Lord-street, Liverpool.

BUILDING INSPECTOR, &C. (SCARBOROUGH, April 2nd).—For the Corporation. (1) Building inspector; salary £130 per annum. Mr. H. W. Smith, A.M.I.C.E., Town Hall, Scarborough. (2) Temporary architectural draughtsman; salary £2 2s. per week. Mr. John E. T. Graham, town clerk, Town Hall, Scarborough.

CLERK OF WORKS (PONTEFRACT, April 7th).—For the Rural District Council. Mr. Wm. A Glover, clerk, Pontefract Union Offices, Pontefract.

CLERK OF WORKS (HAM, SURREY, April 4th).—For the Urban District Council. Salary £3 3s. a week. Mr. W. Warner, Kingston-road, Ham.

ELECTRICAL ENGINEER (DEWSBURY, April 9th).—For the Corporation. Salary £250 per annum. Mr. G. Trevelyan Lee, town clerk, Town Hall, Dewsbury.

SURVEYOR, &C. (SWADLINCOTE, April 11th).—For the Swadlincote District Urban District Council. Salary £200 per annum. Mr. W. A. Musson, clerk, Market-street, Ashby-de-la-Zouch.

Head Office for the United Kingdom—
17 and 18, CORNHILL, LONDON, E.C.
D. C. HALDEMAN, General Manager.

ELECTRICAL ENGINEER.—For the British Electric Traction Company. Managing Director, British Electric Traction Company, Donnington House, Norfolk-street, London, W.C.

SURVEYOR'S ASSISTANT (LOUGHBOROUGH, LEICS, April 5th).—Salary £2 2s. per week. Mr. A. H. Walker, A.M.I.C.E., borough surveyor, Loughborough.

SURVEYOR'S ASSISTANT (EASTBOURNE, April 4th).—Salary £80 per annum. Mr. R. M. Gloyne, A.M.I.C.E., borough engineer, Town Hall, Eastbourne.

SCHERING'S NEW DIETETIC.

This is a new albumen preparation for domestic use. Its constituents, similar to milk, especially Human Milk, give it a peculiar value.

SANOSE

SANOSE is an odourless and tasteless white powder, forming an emulsion when stirred in water.
THE MEDICAL PROFESSION strongly recommends it in cases of Anæmia, Dyspeptic troubles, Consumption, and in Cachectic Women.

For literature see "THE THERAPIST," November, 1897, and January, 1898.

Price 1s. per ounce; 3s. 6d. per 4 ounces.

Apply to all Chemists and Druggists, or to **A. & M. ZIMMERMANN, 9-10, St. Mary-at-Hill, London. E.C.**

SEWAGE FARM MANAGER (LEEDS, April 6th).—City Engineer, Leeds.

SURVEYOR, &c. (KINGSWOOD, April 7th).—For the Urban District Council. Salaries £85 and £50 respectively. Mr. Percy Baldwin, clerk, Council Offices, Kingswood.

Contracts Open.

The dates given below are the latest up to which tenders can be received.

BATH—April 2nd.—Reservoir, &c.—Mr. E. H. Sheppard, surveyor, 3, North-parade, Bath.

BUXTON.—April 2nd.—Heating.—Mr. S. Selby, 21, High-street, Buxton.

CONGLETON (CHESHIRE).—April 2nd—14th.—Water-supply Works.—Mr. C. Russell Hall, West-street, Congleton.

BATTLE (SUSSEX).—April 4th—Drain.—Mr. Henry Card, county surveyor, County Hall, Lewes.

GLASTONBURY.—April 4th.—Sewer, &c.—The Borough Surveyor, Council Offices, Glastonbury.

PUDSEY.—April 4th.—Sewers.—Mr. J. Jones, surveyor, Council Offices, Pudsey.

EPPING (ESSEX).—April 5th.—Sewers, &c.—Mr. Edmond Egan, A.R.I.B.A., engineer to the Council, Holmdale, Loughton, Essex.

BISHOP AUCKLAND.—April 4th.—Sewers, &c.—Mr. C. Johnston, surveyor, 1, Cradock-street, Bishop Auckland.

CROMARTY (SCOTLAND).—April 4th.—Sewerage Works.—Mr. James Fraser, civil engineer, Inverness.

ABERDEEN.—April 5th.—Sewerage Works.—Surveyor's Office, Town House, Aberdeen.

JARROW.—April 5th.—Sewers.—Mr. J. Petree, borough surveyor, Jarrow.

MOORVILLE (NEAR STANWIX, CARLISLE).—April 5th.—Sewer Pipe.—Mr. Wilfrid Crosthwaite, sanitary inspector, Stanwix.

NANCY.—April 5th.—Drainage Works.—Municipal Authorities, Nancy.

HOVE (SUSSEX).—April 6th.—Sewer.—Town Surveyor, Town Hall, Hove.

POKESDOWN (NEAR BOURNEMOUTH).—April 9th.—Sewers, &c.—Mr. Edward Wembridge Ingamells, engineer and surveyor, Council Offices, Pokesdown, Bournemouth.

COMPETITIONS.

CRICKLADE (WILTS), April 30th.—Water Supply Plans.—The Cricklade and Wootton Bassett Rural District Council invite engineers to forward a report, with plans and estimates, for furnishing an effective system of water supply to the town of Cricklade, Wilts, exclusive of the cost of the land or easements, but inclusive of all other expenses. Premiums of £21 and £10 10s. will be given for the plans which the Council shall adjudge to be first and second in order of merit. Mr. Harry Bevir, clerk, Union Offices, Wootton Bassett.

FORMBY (LANCS), July 1st.—Sewerage Scheme.—The Formby Parochial Committee invite competitive schemes for the sewerage of a portion of the township of Formby. Premiums are offered amounting to £100 for the scheme considered first in order of merit, £50 for the second, and £25 for the third. Mr. J. H. Havelock Sutton, Piercefield-road, Formby. A professional assessor will be appointed to adjudicate upon the plans.

To Surveyors, Sanitary Inspectors, &c.—First-class Cycles at reasonable prices. Don't place your orders elsewhere until you have seen our post-free catalogue.—MELROSE CYCLE COMPANY, Coventry.

DR. TIBBLES' VI-COCOA.

ARTICLE NO. 2.

THE VALUE OF KOLA.

Dr. Tibbles' Vi-Cocoa is a carefully-prepared Cocoa made from the finest Caracas brand, with the addition of definite proportions of malt, hops, and Kola. The object in adding these is to give the Cocoa the digestive properties of malt, the tonic properties of hops, and the restorative and refreshing properties of tea. The success which has followed the introduction of this preparation is shown by the attempts that have been made by a well-known firm of Cocoa manufacturers to throw discredit on the use of Kola. This has been done by quoting utterly erroneous statements from a medical journal which is almost unknown to the medical profession, and is not taken in by the leading medical libraries.

It would have been useless to attempt to decry the value of malt and hops, but the general public are probably not quite so familiar with the facts concerning Kola.

But the published evidence as to the value of Kola is so extensive and overwhelming that no medical journal of any standing would risk its reputation by denying that Kola possesses the same active principle as tea or Cocoa, or by venturing to assert that it possesses injurious properties.

Kola has several times been carefully analysed, and has been found to contain caffeine, the same active principle as tea and coffee, as well as theobromine, which is the active principle of Cocoa, and no injurious ingredient whatever. There are many people who find that Cocoa alone does not produce the same effect as tea, that it does not remove the sense of fatigue after prolonged muscular exertion, and that it does not cause the same feeling of alertness or active brain power that is produced by pure coffee.

On the other hand, in some people tea produces a feeling of nervousness and tremulousness, especially Indian or Ceylon tea, and in others coffee causes constipation. These effects are due probably to minute quantities of volatile substances present in tea and coffee. The use of Kola is not known to produce any injurious effect whatever, whilst it contains the same

active principle as tea and coffee, to which they owe their restorative properties, &c. The addition of Kola to Cocoa, therefore, improves the Cocoa by increasing its invigorating property without the corresponding disadvantages that some persons experience from the use of tea and coffee.

But this is not all. Cocoa in the pure state contains nearly half its weight of fat, which is apt to disagree with delicate stomachs, and is, therefore, generally removed by Cocoa manufacturers. But Kola contains only 1·5 per cent. of fat. On the other hand, Kola contains 42·5 per cent. of starch, but Cocoa only 14 to 18 per cent. It is, therefore, more of the nature of a food than Cocoa. Consequently, it is a valuable addition to Cocoa, whether as an invigorant or as a food.

THE USE OF MALT.

The valuable properties of malt in aiding digestion are now everywhere recognised by the medical profession, so that malt extract has become a household word. Malt contains a peculiar principle known as diastase, and which possesses the property of rendering the starch soluble, and thus converting it into a form in which it is readily absorbed, and acts as a nourishing food. This alteration in starch and starchy foods is partly performed by the saliva before digestion in a healthy body, hence the importance of well masticating all starchy food, such as bread and potatoes.

The process is subsequently completed by the pancreatic juice. But in weak states of health, in wasting diseases and consumptive patients, and in the case of busy people who bolt their food, the use of malt extract considerably aids the digestion of starchy foods, and thus increases its nourishing properties. Obviously, therefore, the addition of malt must increase the solubility of the starch present in Cocoa and in the Kola, and increases its value as a food.

THE USE OF HOPS.

In connection with ale and beer the tonic value of hops is so widely recognised by Britons and Germans all over the world as scarcely to require attention to be directed to the fact.

It may, however, be pointed out that, apart from their use in alcoholic liquors and beverages, hops have a distinctly beneficial action of their own.

The bitter principle of the hop has a decided tonic effect on the digestive organs, and the sedative principle it contains tends to calm disordered nerves, hence it is peculiarly fitted to relieve cases of indigestion in which the stomach is in an irritable and exhausted state. By the addition of a carefully-prepared extract of hops, freed from all the insoluble parts, an excellent tonic effect is given to the Cocoa, and the large class of temperance advocates are thus enabled to enjoy the advantage of the hop without the disadvantages of alcohol.

THE COCOA

employed in the preparation of Dr. Tibbles' Vi-Cocoa is the finest variety in the market. Anyone who is accustomed to the use of Caracas Cocoa will readily recognise its delicious flavour. The extract of malt is made from the finest pale malt, and the extract of hops from the best and most fragrant quality of Kentish hops. The Kola nuts are carefully chosen, and particular care is taken to secure the best quality in the market. These ingredients are specially prepared by one of the leading firms of manufacturing chemists, which is well known for the care taken with the preparations that they make. The bitterness of the hop is masked by the flavour of the Cocoa, and the starch of the Cocoa and Kola is rendered soluble by the diastase present in the malt. It would be difficult to contrive a more perfect beverage for daily use.

GUARANTEE.

As a result of trade jealousy consequent upon the unprecedented success of this unique preparation, derogatory statements devoid of the slightest particle of truth are being widely circulated.

The Proprietors of Dr. Tibbles' Vi-Cocoa guarantee that each package is absolutely beneficial to the most delicate invalid or the youngest infant.

A little book containing the reports of the very highest medical experts and analysts in the United Kingdom, showing the advantages of Dr. Tibbles' Vi-Cocoa over all other food producers, will be forwarded to any medical man post-free on application (a postcard will do), to any address, also a large sample tin.

Address—DR. TIBBLES' VI-COCOA, LIMITED, 60, 61, and 62, Bunhill-row, London, E.C.

SITUATIONS.

VACANT.

☞ *Advertisements of Situations Vacant are inserted at the rate of Sixpence per line (prepaid), minimum three lines — eight words to line. Special rates for a series.*

WANTED.

THE SANITARY RECORD *will be found an excellent medium for those who are desirous of seeking Situations in the Offices of Surveyors, Sanitary Inspectors, Sanitary Engineers, Architects, &c. The charge for such advertisements (prepaid) is Sixpence per line. Minimum three lines—eight words to the line.*

☞ **Advertisements for this Department must reach us by Tuesday morning in each week, at latest.**

SANITARY INSTITUTE EXAMINATIONS.

TUITION BY CORRESPONDENCE.

An Engineer and Surveyor (Mem. San. Inst.), Certificated Surveyor and Inspector, prepares students for these Exams. by Correspondence through the post.

Fees strictly moderate. Cramming studiously avoided.

The course of tuition is arranged so as not only to qualify the student for passing the exams., but what is of equal importance, viz., that he may become a thoroughly efficient Inspector.

On successfully passing the exams., all possible assistance and advice is given to help forward intending candidates for public offices.

Many of my old pupils are now filling positions with salaries of over £120 a year.

For terms, &c., address "C. E.," care SANITARY RECORD, 5. Fetter-lane, London, E.C.

SANITARY ASSOCIATION OF SCOTLAND

EXAMINATIONS IN SANITARY SCIENCE.

Examinations for Certificates of Competency in Sanitary Science are held each year as follows, viz.:—In Glasgow in April, in Edinburgh in October, and at such other time and place as the Board of Examiners may determine.

Entrance Fee £2 2s.

For further particulars apply to

GEORGE MIDDLETON, M.A., LL.B.,
Writer, 92, Bath Street, Glasgow,
Secretary to the Board of Examiners.

A Stamped Addressed Envelope must accompany all letters requiring an answer.

SANITARY INSTITUTE EXAMINATIONS.

SPECIAL Corresponding Classes for the **Practical Sanitary Science,** and **Sanitary Inspectors' Examinations** of the **Sanitary Institute, 1898,** conducted by a gentleman holding appointments as Urban District Council Engineer and Sanitary Inspector, holder of three certificates from the Sanitary Institute, First-class Honour Medallist Hygiene, &c. Hundreds of successes.—For all particulars, testimonials, &c., apply Mem. San. Inst., Office of THE SANITARY RECORD, 5, Fetter-lane, London E.C.

OFFICIAL ADVERTISEMENTS.

THE SANITARY INSTITUTE.
EXAMINATIONS IN SANITARY KNOWLEDGE.

The next Examination in PRACTICAL SANITARY SCIENCE and for SANITARY INSPECTORS will be held in London on May 6th and 7th.

The last day for receiving applications for examination is April 23rd.

Forms of application and full particulars can be obtained at the office of the Institute, Margaret-street, London, W.

ROYAL BURGH OF EDINBURGH.—The Corporation invite APPLICATIONS for the Office of CHIEF SANITARY INSPECTOR.

Salary £400 per annum.

Copies of the regulations for regulating the duties of the office may be had from the subscriber, with whom applications must be lodged not later than the 5th proximo.

THOMAS HUNTER, W.S.,
Town Clerk.

City Chambers,
22nd March, 1898.

IMPORTANT ANNOUNCEMENTS.

WILL SHORTLY APPEAR IN THE

Sanitary Record

A SERIES OF ARTICLES

ENTITLED—

"THE CHEMICAL AND BIOLOGICAL EXAMINATION OF WATER,"

BY

C. G. MOOR, M.A., F.C.S.

These Articles, which have been expecially written for THE SANITARY RECORD by Mr. Moor, will be fully illustrated, and will embody the results of the latest researches on this all-important subject.

The writer holds a unique reputation as joint author (with Mr. T. H. Pearmain) of "Applied Bacteriology" and "Aids to the Study of Bacteriology," both of which works have received high encomiums from the *Lancet*, the *British Medical Journal*, the *Chemical News*, &c., and we have no hesitation in commending this new series to the notice of all Public Bodies who are interested in the purity of public water supplies.

A

New Series of Articles

BY

W. J. DIBDIN, F.I.C., F.C.S.,

Late Chemist to the London County Council, Author of "The Purification of Sewage and Water," &c.,

WILL COMMENCE IN

The Sanitary Record

AT AN EARLY DATE.

Mr. Dibdin has chosen for his subject—

"LIME MORTAR AND CEMENT: Their Composition and Analysis,"

And the Articles will prove invaluable to Surveyors, Municipal Engineers, &c.

The date of publication will be duly announced in this column.

NOTICES.

ANNUAL SUBSCRIPTIONS. — The Annual Subscription to "The Sanitary Record," paid in advance, is 12s. 6d. This includes postage, and a Copy of the Diary, post free.

SUBSCRIBERS RESIDING in SCOTLAND and IRELAND are requested to pay by P.O. and NOT *by cheque. If cheques* BE *sent they must be drawn for 13s.*

MSS. cannot be returned unless accompanied by a stamped directed envelope.

Advertisements cannot be inserted unless received before Four o'clock on the TUESDAY of each week.

All communications should be addressed to the EDITOR, at 5, FETTER LANE, London, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, Ld.

THE

Sanitary Record,

APRIL 8, 1898.

Notes.

Recovery of Tolls under Markets and Fairs Clauses Acts.

WE have from time to time been asked to advise as to the powers of a Local Authority who have adopted the Markets and Fairs Clauses Act, 1847, to recover tolls on marketable articles sold outside the precincts of a market. As bearing on the subject, a case—Ross *v.* Taylerson, decided in the Queen's Bench Divisional Court on

January 19th (62 J.P. 181)—will be found useful to many of our readers and to Local Authorities. The case was an appeal from the Justices in and for the city of Liverpool, who had convicted the appellant (Ross), on the information of Edward Taylerson (the respondent), a servant of an association of retail dealers, many of whom deal in tollable articles in a place in which the Markets and Fairs Clauses Act, 1847, apply, under Sec. 167 of the Public Health Act, 1875, and who had taken proceedings as a party aggrieved under Sec. 253 of the Act for the recovery of penalties under Sec. 13 of the Markets and Fairs Clauses Act, 1847. It appears that the appellant, not being a a licensed hawker, sold in Adelaide-street, about a quarter of a mile from his shop, in the said city of Liverpool, certain marketable articles, to wit, potatoes and vegetables, in respect of which toll was authorised to be taken in the wholesale and retail fruit and vegetable market in the said city, and for which no tolls had been demanded or paid by the Local Authority. It was contended on the part of the appellant that the Markets and Fairs Clauses Act, 1847, does not extend to the markets and fairs established in Liverpool, and that the informant was not a party aggrieved within the meaning of Sec. 253 of the Public Health Act, 1875 (under which proceedings for a recovery of penalties may be instituted either by a Local Authority or a party aggrieved). These objections were both over-ruled, and the conviction of the magistrates was affirmed.

The Inspection of Private Schools.

An important question was raised at the meeting of the St. Pancras Vestry. Very properly the Health Committee of the Vestry had determined that the private schools in their district shall be officially inspected by the officers of the Vestry, just the same as the public institutions. Although the high-schools may be carried on for private profit, in them is gathered together a large number of young people from all parts, and it is the duty of the Authorities to see that the conditions prevailing are such as will promote and ensure their health and well-being. Acting on the instructions of the Committee, the female Sanitary Inspector sought admission to the North London Collegiate and Camden School for Girls, Sandall-road, but entrance was refused; and the Clerk of the Governors intimated that admission would not be granted except it be ordered by the High Courts of Justice. The Health Committee reported this fact to the Vestry, also stating that the solicitor held that the Committee had no alternative but to enforce the Vestry's statutory powers by legal proceedings, and that counsel had been retained to represent the Vestry in any legal proceedings.

The Folly of Refusal.

We regret that the managers of so important a school should have acted so unwisely as to refuse to have their premises inspected. The request from the Vestry cast no aspersion upon their institution. In fact, several of the members spoke from personal knowledge of its high character and good conduct. But public bodies cannot take such things for granted, and invidious distinctions cannot be made. But why should entrance be refused? If all is as it should be, the Governors have everything to gain and nothing to lose by admitting the Inspector. A certificate from a professional man is good in itself, but it must be borne in mind that he is called in to certify a certain thing, and the bias of his report is bound to be in the direction of what is wanted. But it would be infinitely better to be able to publish a guarantee from the Local Authority that every precaution was taken to ensure the perfect sanitation of the school premises and their surroundings. We trust, therefore, that wiser counsels will prevail, and that the Vestry will not have to take the threatened proceedings. The Governors will, we believe, lose the day, and in all probability have to pay dearly for their unwise refusal. We may state that the action of the Health Committee was heartily approved by the Vestry.

Gipsy Dislike of Sanitary Law.

The Medical Officer of Blackpool has just had a bout with a gipsy, who had pitched his tent within the borders of the district. It was found that in the encampment were children suffering from infectious disease, and the Medical Officer of Health very properly desired their removal to the Sanatorium. The father (named Boswell) declined to let the children be taken away, and resisted the order of the magistrate, notwithstanding that the doctor and Inspector had the services of the police when they attempted to enforce it. On Friday the gipsy was taken before the magistrate, and on being asked to plead, Boswell humbly begged pardon for what he had done; but the screams of his wife and children had unnerved him, and he did not know what he was doing. He was asked if he would allow his children to be taken, and he replied that there was no necessity for their removal. He argued with the magistrates, and appealed for the children not to be sent away. He would give the whole world, if he could, rather than that they should go. He was again asked, and said it would make his heart bleed to say "Yes." Being warned that he would be seriously dealt with if he did not consent, Boswell asked what the penalty would be, and was told that even if the penalty were enforced the children would still be taken. After consulting with another gipsy, Boswell consented to let the children go, and later in the day they were taken to the Sanatorium, along with the father, who will remain with them. It seems hardly credible that such ignorance should prevail to-day, and yet there are people who defend these nomads in their refusal to conform to the laws of health and safety. The history of the small-pox at Middlesbrough should be a warning to all of the danger incurred by allowing these wandering tribes to travel unmolested throughout the country.

The Pollution of Rivers.

One of the difficulties anticipated in connection with the Pollution of Rivers Prevention Bill now before Parliament is that, as the Bill does not extend to Scotland, County Councils immediately south of the Border will have an imperfect jurisdiction over streams which lie partly in Scottish territory; and the President of the Local Government Board has therefore been appealed to

to introduce a short Bill, consisting of a single clause, to enable such County Councils in England to co-operate with Scottish County Councils immediately north of the Border in the formation of joint committees for the prevention of the pollution of such streams as are subject to a divided jurisdiction. Mr. Chaplin, though declining to introduce such a Bill on behalf of the Government, has given an assurance that, in the event of one being introduced by a private member, it should receive his support; or, he suggested, a clause to the same effect might be inserted in Committee on the Rivers Pollution Prevention Bill, providing for the appointment of joint committees to meet the end in view.

The Spey Case.

An important case of river pollution has been occupying the attention of the Scotch Courts. The case is that of the Spey, and also of a small tributary called the Ringorm Burn, near Aberlour. The complainers are the Countess of Seafield and several other riparian owners; and the pollution complained of was said to be caused by the discharge of the waste products of Macallan Distillery into the river. There has been within recent years a great extension of the distillery industry (that is a fact for temperance reformers to ponder), and on Speyside in particular the industry has made great strides. The consequence is that the quite insignificant pollution which could be laid to the charge of distilleries along the river a few years ago has now grown to be an intolerable nuisance, and has proved the ruin of valuable salmon fishings. These facts have been established by the evidence which has been led at great length in the Court of Session. The offending distillery has been found "guilty," but before its work is interfered with by interdict, it has been given a chance to reform; and the case has meanwhile been stayed to allow time to test the effectiveness of certain filter beds and other remedial works designed to prevent the pollution.

A Fever Hospital Case

A pretty little fight has arisen between the Local authority of the town of Hawick and the Local authority of the Hawick District of the County, as to the liability for the expense of maintenance of a patient in the Hawick Fever Hospital. The patient belonged to the County district, and the case had been notified by the County Medical Officer, but as there was no fever hospital for the County, the patient was removed to the Hawick Hospital. In point of fact, the removal was at the instance of the patient's private medical attendant, but it was contended that as he had been detained by the County Medical Officer, who also agreed to the removal, the County should be liable. On the other hand, it was argued that the case was just the same as if a person had gone into hospital of his own free will, that the notification by the Medical Officer was merely the performance of a statutory duty, and that his approval of the removal to hospital could not constitute a ground of legal liability. The Court upheld the latter contention, though evidently not without strong sympathy for the view taken by the Burgh Local Authority. The hardship of the case for them lay in this, that it was apparently impossible to recover the expense from the patient himself, and of the two Local Authorities concerned, it seemed most fitting that the Authority for the district where the case occurred should be responsible. There was, however, no special arrangement between them, and though such an adjustment of the responsibility might seem equitable, it could not be legally enforced. It was an unfortunate instance of the friction that will occasionally arise between bodies that are really working for the same object.

The Small-pox at Middlesbrough.

We are glad to observe that the epidemic of small-pox at Middlesbrough is beginning to show some real indication of being at last on the decline. The sudden recrudescence, which was no more than was anticipated, appears to have spent itself; and the number of cases reported from day to day, though still sufficiently serious, is so perceptibly diminishing as to warrant the expectation of the Authorities that it will not now be long ere the scourge is effectually stamped out. By the end of March about 1200 cases of small-pox had been notified, and as the epidemic is by no means over yet, before we have heard the last of it this number will probably be considerably increased. Such an experience as Middlesbrough has passed through, with all its attendant loss and suffering, is enough to furnish matter for grave reflection to the veriest infidel in the benefits of sanitary administration, and the virtues of vaccination as a prophylactic.

Oysters and Typhoid Fever.

The deputation which waited on Mr. Chaplin the other day at the Local Government Board Office, to impress on him the necessity for legislation in order to check the cultivation of oysters and other shell-fish in close proximity to, or actually under discharges of sewage, or to prohibit the sale of bivalves reared in such dangerous localities, has opened the eyes of the public to a very alarming state of things. The speakers included a number of representative members of Parliament and Medical Officers, and their views are entitled to the greatest weight. Their opinions were unanimous as to the dangers connected with the present unrestricted methods of oyster cultivation, and the powerlessness of Local Authorities to deal with the matter. One and all testified to the very serious prevalence of typhoid and other forms of enteric fever due to this cause; and it was stated that Local Authorities had no means of preventing the sale of shell-fish within their districts, even though they had the clearest evidence that the consumption of such shell-fish had been the cause of enteric fever, and that they were derived from a source known to be contaminated with sewage.

The Magnitude of the Danger.

Now this is undoubtedly a very grave state of matters, and the danger is all the greater because oysters swarming with typhoid germs may appear quite sound to the naked eye. Moreover, the danger is not confined to any one class; for, if oysters are chiefly consumed by the rich, the poorer classes are great consumers of mussels, cockles, and peri-

winkles, all of which molluscs are equally exposed to contamination by sewage discharge. The consumption in London is very large, and frequently in a raw state. Completely reliable statistics can hardly yet be expected as to the rate of mortality to be attributed to this cause, but some figures were submitted which we believe are trustworthy. Dr. Nevin, of Manchester, said that one-tenth of the cases of typhoid in that city were traceable to such impregnated food; and Dr. Newsholme, Medical Officer for Brighton, stated that he had ascertained that contaminated oysters were responsible for one death out of every three from typhoid in the fashionable English watering-place.

The Position of Brighton in the Question.

The lead in the movement for legislation has been taken by Brighton, which feels that its reputation as a health resort is deeply affected. Sir John Blaker, the Mayor, said that they had been compelled to take action in consequence of the alarming report of their Medical Officer. Moreover, the report of the Medical Department of the Local Government Board in 1896 on the conditions under which oysters and other edible molluscs are cultivated on the coasts of England and Wales, proved that in many places they were liable to sewage contamination of the grossest kind, and that the consumption of shell fish derived from these sources was a serious danger to the public health. The Corporation of Brighton accordingly, on consideration of these facts, attempted to deal with the question in 1896 by private legislation; but the fact that the report of the Medical Department of the Local Government Board had not then been presented was urged by the Board of Trade as a reason for not legislating by private Bill, but by a public Bill after the result of the inquiry was made known. Brighton, however, was resolved that the matter should not rest; and Sir John stated that they had received the active support of twenty-seven large towns who were interested in the question, and a resolution had also been passed by the London County Council approving of their action.

Mr. Chaplin's Promises of Legislation.

Such a strong representation of the case, backed as it was by a body of expert opinion of the greatest weight, including Sir William Priestley and Dr. Collingridge, Medical Officer for the Port of London, could not fail to produce a deep impression on Mr. Chaplin. And that he was so impressed was evident from his reply to the deputation. He admitted the gravity of the situation, and promised to see what could be done. He added that he thought the time had arrived for legislation. The question was, however, larger than he had believed, for the danger connected with the consumption of the smaller and cheaper shell-fish was an aspect of the case that he had not considered, and inquiries would have to be made before action could be taken. But with regard to oysters, he hoped before long to adopt measures that would be satisfactory. He did not indicate what these would be, but no doubt he will give effect as far as possible to the views which were urged upon him; and these were, that Local Authorities should be empowered to prevent the sale within their districts of shell-fish from any source proved to be contaminated by sewage, that they should also be required to construct their sewage outfall works in such a manner as not to contaminate oyster beds, and that the owners of the oyster beds should be compelled to keep them at a distance from the sewers.

Vital Statistics for Scotland.

The Report of the Registrar-General on the Births, Deaths, and Marriages for Scotland in 1897 was issued the other day. As usual, a document of this nature bristles with figures; and we only extract a few, relating to the death-rate and the vaccination returns. The death-rate for Scotland in 1897 was 18·7 per 1000; the highest rate, 20·8, being recorded in the principal urban districts; and the lowest, of 16·2, in the mainland rural districts. The percentage of successful vaccinations of children, whose births were recorded, was 85·135. In 2·2 per cent. of the cases, certificates of postponement were granted; 0·421 per cent. of the cases were described as insusceptible of vaccination in consequence of some constitutional peculiarity, and 0·221 per cent. in consequence of their having been vaccinated, but by persons who were not qualified to grant certificates; 9·425 per cent. died before vaccination; and 2·598 per cent. were removed from the district in which they were born prior to vaccination, or were otherwise unaccounted for. There were seven deaths from small-pox in the eight principal towns during the year.

DIET IN THE TREATMENT OF INEBRIETY.

For a long time persons have urged that diet was the real remedy for inebriety. Yet, when it was applied in certain cases, no better results were obtained. The drink symptom remained. Occasionally the change from a meat to a grain diet, or the reverse, was followed by the subsidence of all desire for spirits. In a continuous drinker a general diet of both meats and grains appears to meet the demands of a disordered nutrition and semi-starved condition better than any special articles of food. In the periodic cases an albuminous or proteid diet is often decidedly injurious. In some cases an intense craving for meat or for starchy foods precedes the drink paroxysm, which subsides when the craze breaks out. The intimate relation between foods and the drink paroxysm is very prominent in many cases.

In some cases excessive meat eating is associated with great irritability and sensitiveness of the brain and nervous system. The change of diet is followed by a great improvement of mental activity. It would appear from a study of many cases that so far no general rule can be found, and each case must be studied from the facts of its history. Thus, in some cases a meat diet is literally poisonous, and its removal is the first essential for a cure. Again, a grain or fruit diet is clearly injurious, and more rapid recovery follows a change. In all cases states of starvation and anti-intoxications exist, the removal of which is of equal importance to that of spirits. The study of the diet brings out many unsuspected causes, which require removal and treatment before a cure can be effected.

NOTES ON
PRACTICAL SANITARY SCIENCE.

By WILLIAM H. MAXWELL.

Assistant Engineer and Surveyor, Leyton Urban District Council, Author of "Drainage Work and Sanitary Fittings," "Ventilation Heating, and Lighting," &c., Certificates of the Association of Municipal and County Engineers, and Sanitary Institute.

No. 56.—REFUSE DESTRUCTORS.

(*Continued from page* 334.)

The "Bennett-Phythian" Destructor.

The "*Bennett Phythian*" constant high-temperature destructor is an apparatus which has very recently made its appearance, and a furnace of this type has been erected by the Farnworth Urban District Council. The special features of the furnace will be apparent from an inspection of Figs. 24, 25, and from the following description:—When at work the fires are burning upon the grate in two of the cells, the other being empty. The central cell obtains a maximum heat, and when it requires re-charging the grate is moved to bring that part which was in the central cell into the empty side cell, and that which was in the outer cell into the centre, and thus, without cooling the central cell or furnace, a fresh charge is brought into it which had been gradually increasing in heat. The grate that has been moved into the empty cell is then clinkered and re-charged, and the blast turned on to it, when it gradually increases in temperature, the products of combustion from it passing over the hotter fire in the centre, until that in its turn requires re-charging; and thus the side cells are alternately re-charged and the grate moved to carry the charge into the central cell. The grate on which the refuse is placed may be moved by the rack-and-pinion arrangement illustrated, but an electric motor may be utilised for this purpose.

Some of the points claimed for it are:—

(1) That it is capable of destroying 24 tons of house refuse in twenty-four hours, and at the same time of raising steam for electric light or other purposes.

(2) That all gases pass over the central cell, where constant temperature is maintained at 2000 deg. Fah.

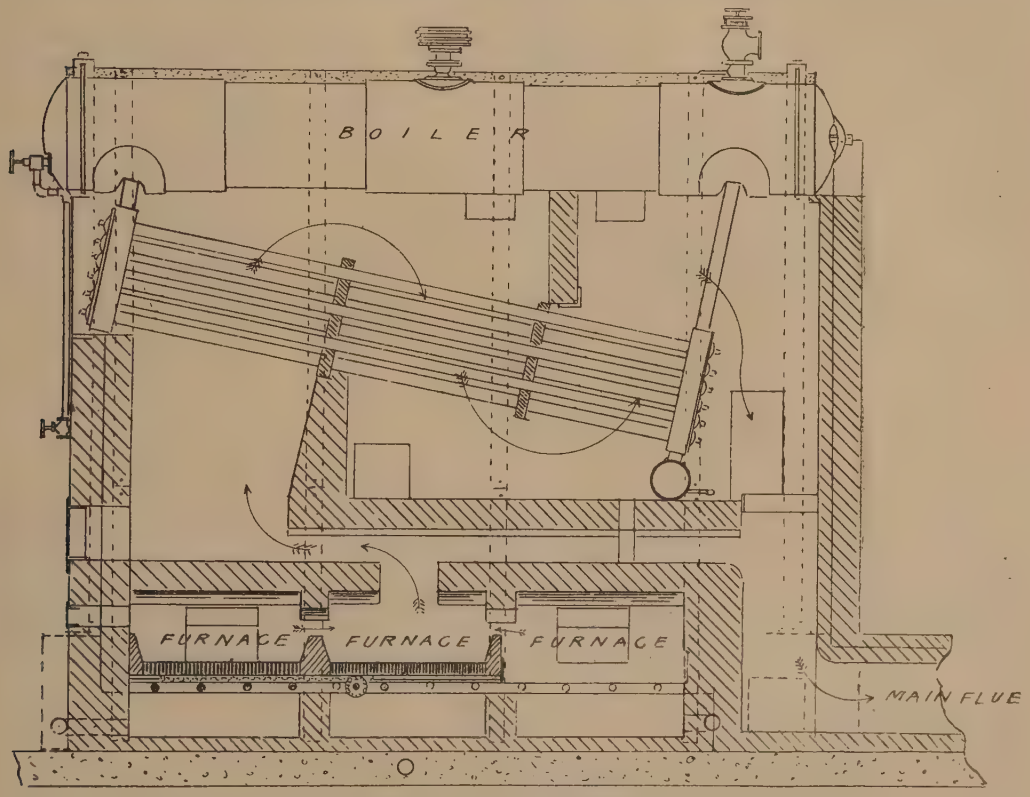

Fig. 24.—Section of the "Bennett Phythian" Destructor.

(3) No elevated roadway is required, and the charging and clinkering are done on the ground level.

The Willoughby Patent Refuse Destructor.

The Willoughby refuse destructor, as now in use at Lewisham, is the most recent type of furnace that has been adopted, and, as will be seen from the accompanying illustrations (Figs. 26 and 27) possesses several entirely new features. It consists mainly of a furnace and a revolving cell.

The *furnace* is placed at one end and fed, not with town's refuse, but with gas coke, coal, or breeze, assisted with a draught forced by Meldrum blowers, so as to give a fire of high temperature.

The products of this furnace escape into a revolving cell.

This *revolving cell* consists of a long tube of iron or steel plate, lined throughout with fire-brick, and fixed at a small angle from the horizontal. The first portion of this cell or tube (Fig. 26) has a diameter of about 8ft., and the lower portion one of about 5ft. Each section is about 23ft. in length. In the inside are projecting fire-brick ledges arranged so as to give a series of longitudinal ribs which serve to catch and carry up the contents of the tube, and drop the same time after time as it passes along the length of the cell.

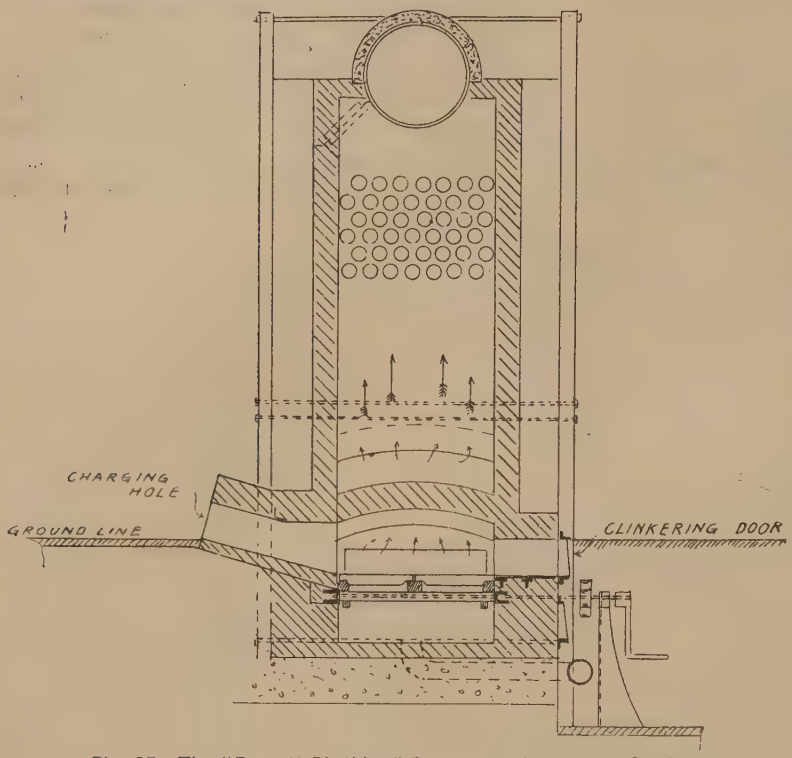

Fig. 25.—The "Bennett Phythian" Destructor: Transverse Section.

The tube is carried within a series of stout rings which run on bearing rollers. One ring is geared o an engine, which gives the rotary motion to the cell and actuates the residue elevator, the feed ram, and the ash screen, &c. The cell revolves slowly, and the speed is regulated according to the nature and condition of the refuse to be destroyed. Sight doors are provided through which the interior of the cell is fully visible.

The refuse is brought, as usual, up an inclined roadway, and delivered on to a tipping platform near the feeding hopper, which is placed over the coke furnace. A large slowly-reciprocating ram enters the base of the hopper and pushes the refuse along a short tube, which terminates at the upper end of the revolving cell. The lower end of the cell opens into a charpit, which serves as a receptacle for the unburnt residue from the cell. Beyond this pit is a multitubular steam boiler and secondary furnace — for use only when the destructor is idle—and flues leading to the chimney.

When the destructor is first put into action, the furnace at the front end is lighted, and a few hours are required to get the cell and walls of the chamber to a glowing heat. Then the ram is started, and about six times per minute a small portion of refuse is passed into the hot cell. Falling as this does immediately in front of the furnace on the red-hot walls of the cell, all light burnable stuff is immediately consumed, and no screens are necessary to keep paper from getting out of the chimney top as in some destructors. The fumes or gases arising from the burning of semi-putrescent matter which constitutes a considerable part of a town's refuse, become thoroughly burnt, having to pass along the whole length of the glowing walls of the revolving cell before finding their way into the flue. No two lots of refuse delivered by the ram fall upon the same spot of the cell at one time, and therefore no heaping up and stewing of green refuse is likely to take place. By the revolving action of the cell,

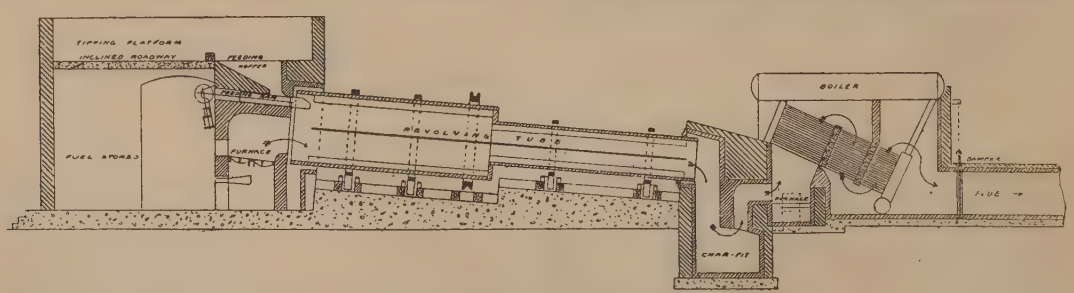

Fig. 26. Section of the Willoughby Patent Refuse Destructor.

and its inclination towards the charpit, the refuse is gradually carried away from the front until what is left unconsumed is delivered into this chamber.

This unburnt residue consists of chards, tins, glass, and cinders, but *no clinkers*. The longer the refuse takes in passing through the cell the less cinders are delivered. These at Lewisham find a ready sale, and the only residue for which there is no market consists of tins, glass, chards, and similar unburnable material. The whole of the residue is delivered in a state of bright incandescence, and is entirely free from any organic matter.

As the residue escapes it is quenched with water, and passed up an elevator to a graduated revolving

The new destructor is also claimed to give the best results in raising steam for electric lighting or other purposes.

In a report of Messrs. Alabaster, Gatehouse, and Co., upon this destructor as now in use in the yard of the Lewisham Board of Works, Molesworth-street, Lewisham, S.E., it is stated that at the time of their visit the whole of the interior of the revolving cell was found to be in a bright-red condition, and full of refuse and flame. Being about 36ft. in length, the progress of the refuse is of considerable duration; and with such a temperature (at least 2000 deg. Fah.) it is impossible for any gases given off by putrescent matter to escape unburned and unpurified.

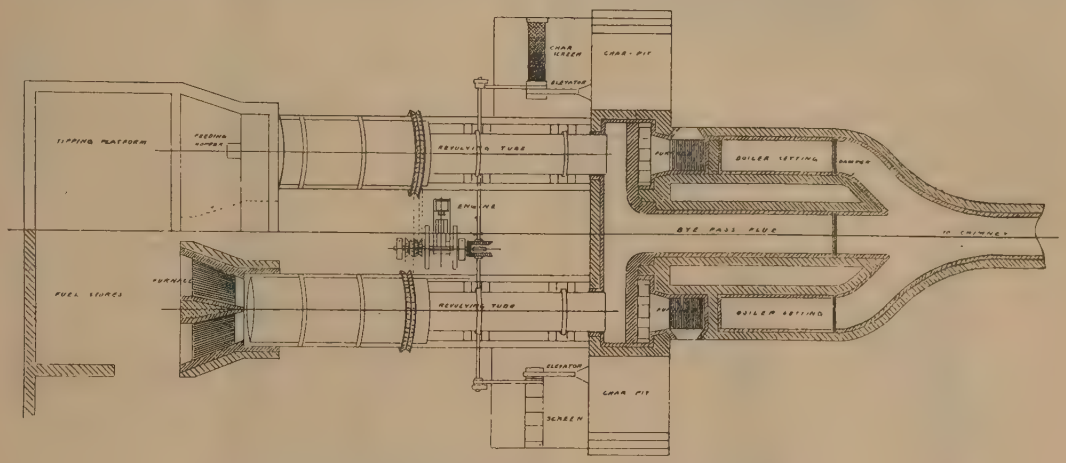

Fig. 27.—Plan of the Willoughby Patent Refuse Destructor.

inclined wire screen, which sorts to size and rejects the tins, sheet iron, &c.; the sand is separated out for the use of builders and others, and the breeze or cinders for fuel.

In the long flue leading to the chimney shaft is a water screen about 4ft. from back to front. This screen separates out the dust from the flue gases, and discharges it with the water into a pit, from which the dust is removed as required.

There is *no clinker* to deal with from the refuse passed through the Willoughby destructor, and at Lewisham, where the first installation of this furnace and plant has been laid down, the only portion of the unburnt refuse which has to be carted away is the chard, &c., amounting to about 4½ per cent. of the refuse treated.

Four men with one such cell as shown in Fig. 26 would, it is estimated from the Lewisham experience, pass through four tons of refuse per hour. One man attends to the ram feeder, one to the coke fire and the engine, and two on the unburnt residue. The wages for four men for this work would, of course, vary with the locality; but, taking a rate of pay of 6d. per hour, the *cost of labour per ton* of refuse passed through the destructor is put down at 8d., and the *cost of fuel* being about 3d. per ton, the refuse, it is claimed, is thus burned, and the residue[138] disposed of at a total cost not exceeding 1s. per ton.

[138] The residue or clinker at some destructor works is a source of profit. At Leyton this is sold by contract at the rates of—clinker, 6d. per load; fine ash, 1s. 4d. per load; the contractor undertaking all cartage and labour of removal.

Mr. H. Graham Harris, C.E., the Engineer appointed by the Board of Works for the Lewisham District, to examine as to the efficiency of the destructor, reported in November, 1897, that the conditions of the agreement of the manufacturers with the Lewisham Authorities as regards the consumption of the furnace and the absence of nuisance had been satisfied. The words of the agreement on this point were as follows:—(*a*) "That the destructor will cremate from 40 to 50 tons of house refuse per day of 24 hours, and that the formation of clinker from house refuse is impracticable excepting as to residue." (*b*) "That the destructor will destroy all noxious and poisonous gases and smells arising from this refuse while cremating."

Professor Dewar caused a good deal of amusement at the Royal Institution on Friday night by producing a milk can, which he had filled with liquid air, and pouring the fluid out, just as one would the more familiar substance, milk. A few years ago, he said, liquid air could only be obtained by the pint, now a gallon of it could be produced with the greatest ease, owing to the improvements in the apparatus for its manufacture. Professor Dewar remarked that many industrial and commercial uses for liquid air had been found, and as its production was cheapened further applications would be sought for.

THE SANITATION OF DOMESTIC BUILDINGS.

By Frank Latham, C.E., M. San. Inst., &c., Assistant Surveyor, Borough of Margate.

CHAPTER VI.

Section 2.

FLUSHING APPARATUS.

Having selected a good and reliable closet, its satisfactory working depends on the efficiency of the flushing apparatus provided. The use of unsuitable flushing apparatus is neither sanitary nor, in the long run, economical, most of the old flushing appliances being great water users with comparatively small results, whereas the flushing could be better done with less trouble and unnecessary waste of water by the use of more perfect systems.

There are numerous descriptions of good flushing apparatus for closets, but before considering these it is necessary to give examples of unsanitary methods in order to guard against them. In most instances where the supply is intermittent, houses

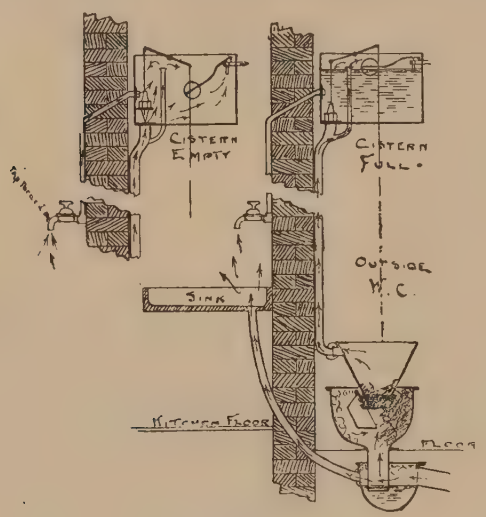

Fig. 69.

are provided with cisterns for storing the water for domestic and other purposes, and sometimes the closets are flushed direct from these cisterns, the result being that the supply may be contaminated with the impure air from the closets through the flush pipe or other intercommunication. Figures 69 and 70 illustrate some defects reproduced from the author's note-book. It is a matter of grave importance that no such direct connection should be allowed, although, without doubt, the number of houses in which such a dangerous defect exists would upon examination be found rather a large one.

Frequently the only flush to a water-closet is by turning on a tap on the water service (Fig. 71). This not only gives an insufficient flush, but is a great water waster, and a very dangerous contrivance for contaminating the water in the pipe or main, especially when the supply is intermittent, or at times when the mains are emptied by accident or otherwise, foul air, and possibly other matters, being sucked into the distribution system. No closet should be flushed off any arrangement in direct connection with the water supply of the house, but be provided with either proper flushing valves or separate flushing cisterns. Flushing valves are now nearly obsolete, and their working not always sanitary, their main faults being that in cases where the flush pipe is on the water service, should the pipes become empty by the water in the main being turned off for repairs, or through

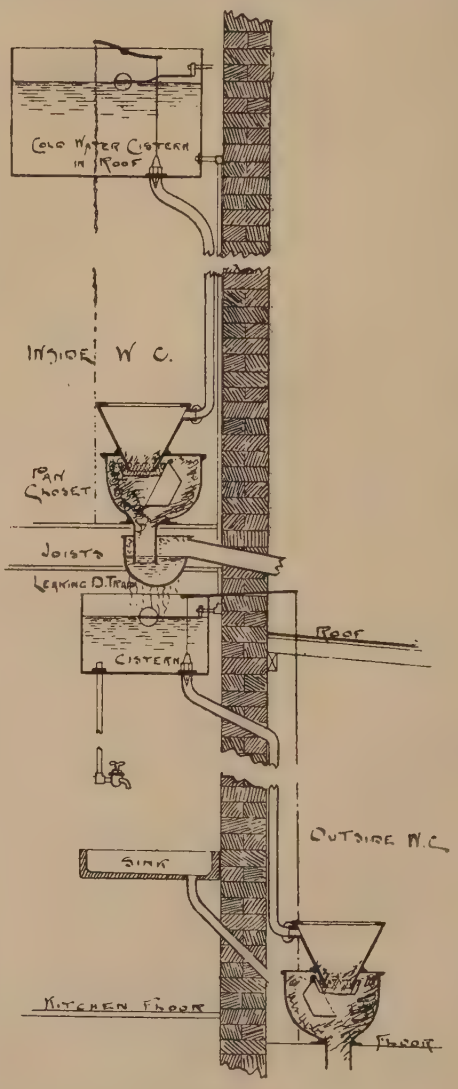

Fig. 70.

the supply being inconstant, the same disadvantages attach to them as to the turn-down tap.

Closets should be provided with syphon flushing cisterns, such as Jennings' (Fig. 72) or Jones and Brice's (Fig. 73), one for each closet, and fixed on the wall 5ft. or 6ft. above the floor on brackets. These cisterns should then be supplied with water by a separate service, either from the main or storage system (Fig. 74). This cistern is connected with the closet by a lead flushing pipe, which

should be carried direct from the cistern to the closet basin, and firmly jointed at each end in the best and strongest manner. It ought not to be less than 1½in. in internal diameter, and that size maintained from the outlet of the cistern to the flushing rim. By using this sized pipe it will be found that the large and quick flush thus provided will more effectively cleanse the basin and drains than a smaller and slower one would.

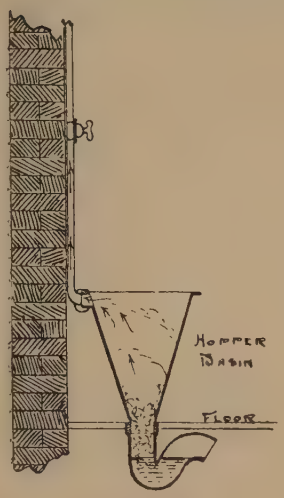

Fig. 71.

Syphon cisterns should not hold less than a two-gallon flush, to be discharged immediately on the handle being pulled, the whole being syphoned out in three seconds. A two-gallon flush is sufficient to cleanse most good closets and drains, where the soil pipe is 3½in. in diameter and the drain 4in. with good fall, but in cases where the drains are 6in. or more it is advantageous to use a three-gallon

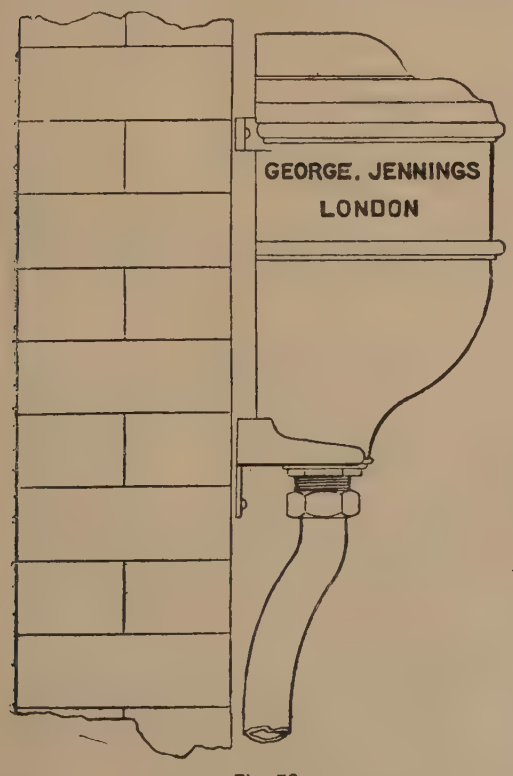

Fig. 72.

flush, *i.e.*, if the water company will allow it. This again shows that now-a-days, when the economical use of water is an important matter, the advantage should be taken of using 4in. drains for ordinary sized houses, as requiring a less amount of water for effective flushing than larger sizes.

Automatic flushing tanks and cisterns, although not so much required in the majority of house

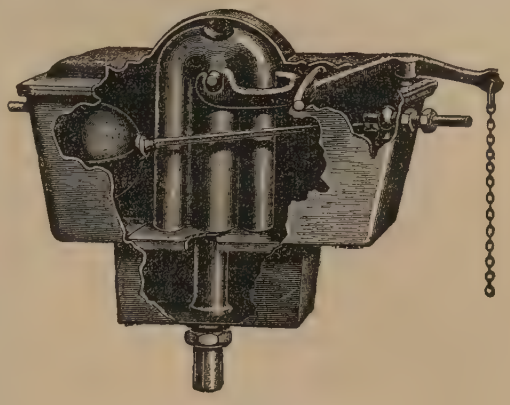

Fig. 73.

drains, are invaluable when fixed at the head of lengths of drains, especially in cases where only a small fall can be obtained. These tanks are generally constructed on the syphon principle with

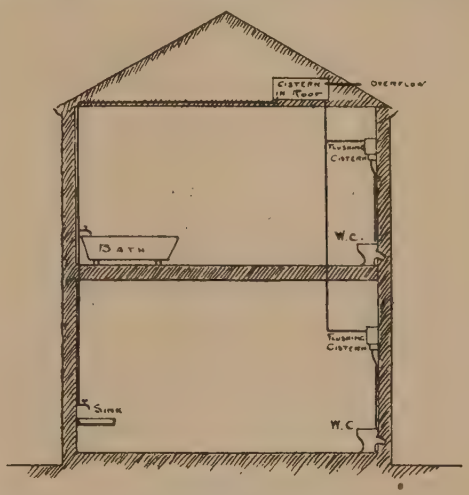

Fig. 74.

delivery of large bore so as to allow of their contents being emptied at once into the drain. They can either be supplied with water from the main or with waste water from baths, lavatories,

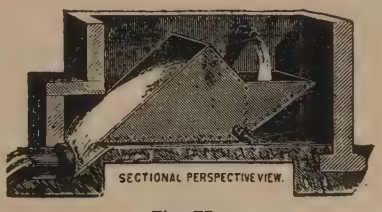

Fig. 75.

sinks, and rain-water pipes, &c., which otherwise would generally dribble down the drain with little cleansing power. They can be obtained to hold from a small to a large amount, the general size

being about eighty gallons. The tip-over contrivance is also a good form of flush. That manufactured by Messrs. Braby and Co. (Fig. 75) has a tipper made in two compartments, so that when the principal or large one is discharging it is replaced by the smaller, which upon being filled outweighs the larger vessel and tips back again, into position. The apparatus is enclosed in a brick chamber and made to discharge into the drain, being fed by the waste water which is conveyed to it by a pipe, and tippers can be obtained to discharge any amount up to two hundred gallons of water at a time.

Trough closets and urinals should always be fitted with automatic flushing cisterns of a capacity suited to the number of stalls and length of the trough. The discharge can be regulated according to the requirements of the apparatus.

EPIDEMIOLOGICAL SOCIETY.

AT a meeting of the above Society, held on March 18th, Professor J. Lane Notter, M.D., President, in the chair, Dr. D. S. Davies read a paper on "Milk-borne Enteric Fever in Clifton," in which he considered the distribution, incidence of attack, and character of illness. The facts of the outbreak already reported in the *British Medical Journal* of December 4th, 1897, page 1669, were shortly as follows:—A brook polluted with sewage passed through a farm K, where the unboiled water of a well sunk close by the stream was used for washing the cans. Milk from this farm was supplied to 57 houses, in 41 of which 101 cases of enteric fever appeared, and 20 other houses in which 33 cases occurred were found to have obtained the same milk from the dairy. A second supply from L, originally pure, but mixed before entering the city with some from K, was distributed to 39 houses, of which 15 were attacked, the cases numbering 37. A third supply, also pure, was distributed on three distinct walks, in two of which no cases occurred; the third remained free until on one occasion, in consequence of the reassembling of the schools causing a sudden increase in the demand, the carrier, meeting the man in charge of one of K's walks, took a quantity of milk from him. Of the 16 houses at which he subsequently called 8 were attacked, and 22 cases occurred; the only case in the twelve houses visited before their paths crossed was that of a servant, who, living close to K's shop, had drunk milk from that supply. Thus 94 per cent. of all the cases in Clifton were clearly traced to the milk from a single farm. The mean death-rate from enteric fever has ever since 1878, when an outbreak was caused by an infected milk supply from Westbury, been only 8·5, as against 19·8 in the 33 great towns; and the cases up to September, 1897, several of which were introduced from elsewhere, had never exceeded 4 in a month. But about the end of September Dr. Davies was informed of an outbreak of "influenza" in certain "houses" connected with Clifton College. Since the inmates of these associated in school with those of the other houses which escaped, he doubted the correctness of the diagnosis, and obtained samples of the blood of the patients for Widal's test, and by October 24th he and Dr. Klein had obtained positive evidence in 38 out of 41 cases, one of the three doubtful cases being verified *post mortem* by the presence of the bacilli in the spleen. The next day, instead of having recourse to the tedious procedure under Section 4 of the Public Health (Amendment) Act, which would have involved the loss of nearly a month, he induced the Sanitary Authority to buy up the whole of the milk from the farm in question for four weeks, meanwhile taking steps to prevent the recurrence of the pollution. The paper was illustrated by several tables, embodying facts not previously published. Thus, on the regular walks, 58 were attacked with 186 cases, and 27 houses with 44 cases obtained milk from two shops supplied with the same milk. Besides these 13 houses with 14 cases obtained theirs from shops not proved to have received milk from infectious sources—that is, 230 of the 244 cases were known to have drunk milk from the one farm, and of the remaining 14, three had very probably done so, three were customers of a shop close to that supplied from the farm, while one, a medical student, and three nurses, may have been infected by neglect of precautions in their contact with the patients. Of the eight college houses, however, five using this milk were attacked, and three with pure supplies were not.

The males of all ages were 80, and the females 164; of the former 65, and of the latter 75 were under 20 years of age; the males between 30 and 35 were 9; the females 63, the excess being mostly domestic servants. Of these, of all ages, 3 were males and 62 females, with 2 and 12 deaths respectively. Of boys at school there were 58 cases with one death, and of girls 52 with four. Four schoolmasters and four mistresses were attacked, one of each dying, while the one medical student and one of the three nurses attacked died. Some of the numbers were too small for safe conclusions, but the low mortality among the cases under 20 years, 6·4, and the heavy rate of 21 per cent. at higher ages, was very striking; indeed, the deaths among the 66 between 15 and 20 were only 6·0 per cent., and those among the 29 between 20 and 25 years were 31 per cent.

The results of 192 cases in which he used Widal's test were positive in 138, all but two of which were clinically confirmed, 14 were doubtful, but in 6 there was clinical evidence of enteric fever, and of the 39 that did not react on the first trial, four, two of which gave positive indications on a repetition of the test, subsequently developed enteric symptoms, but in 35 the negative results of the test were confirmed by the course of the case. He was therefore decidedly of opinion the Widal's procedure afforded valuable assistance in the early stages of the disease, before its true nature could be determined on clinical evidence alone.

Dr. WASHBOURN looked on Widal's test as a valuable aid rather than as an absolute indication, though the alleged reaction in scarlatina was easily distinguished; the scarlatinform rash observed in some cases was frequent in all febrile states. He doubted if enteric fever was ever notified much before the third week from infection.

Drs. CHILDS, BULSTRODE, and SWEETING asked whether there were premonitory and collateral diarrhœa, or secondary cases of typhoid, and criticised Dr. Davies' estimated incubation periods,

and statistical conclusions from too scanty materials.

The PRESIDENT had known enteric fever break out among troops three weeks after their arrival in isolated, even uninhabited regions in South Africa and Afghanistan. The report of the chemical and microscopic examination of the water shown by Dr. Davies was the work of a mere chemist, and useless for practical purposes. There was no doubt as to the connection of the fever with the milk supply; the question was how the milk became infected, and such inquiries should be entrusted to the Medical Officer of Health himself, not to the analyst. Widal's test could be overrated; indeed, he preferred Ehrlich's test of the urine.

Dr. DAVIES replying, stated that a bacteriological examination of the water of the farm was made by Professor McFadyen, but not until October 26th, when large numbers of B. coli were found. There were some secondary cases besides the student and three nurses, one of whom could not have drunk any of the infected milk. The autumnal wave of diarrhœa was below the average, showing that epidemic did not develope from small beginnings, but, like all outbreaks caused by infected milk supplies, it was sudden and simultaneous.

Annotations from Annual Reports.

Proximity of Trees to Dwelling-houses.—The proximity of trees and shrubs to dwelling-houses is not generally considered in the light of a health problem, but the fact that it is to be so considered is raised by Dr. Owen Coleman, Medical Officer of Health, Surbiton, in his Annual Report for 1897. Surbiton, it may be mentioned, is a popular London suburb, where trees and shrubs form a considerable item, both in the front and rear of the dwelling-house. According to Dr. Coleman, "it is not the trees in the roads, whether they are big or little, nor the large forest trees that still fortunately exist in some numbers scattered about the district, that affect the public health, but the perfect jungle that so many householders encourage in their front and back gardens, and seem to love to cultivate, that are so prejudicial. They darken the lower rooms of the houses, keep the ground damp and sour, and obstruct the proper access of fresh and wholesome air to the lower parts of the houses. During the night, when the warm self-contained air naturally rises, and to some extent passes out of the upper part of the house, its place is supplied by air coming in at the basement or ground floor; and if this has to be filtered through bushes and undergrowth mixed with the exhalations from damp soil charged with decaying organic matter, it is small wonder that some households find themselves specially liable to sore throats or indifferent health. These not infrequently are never advised as to the possible cause, but incontinently refer it to the neighbourhood as a whole, and either go on suffering or pack up and leave the place. The big trees (due regard of course being had to their soundness) have an important part in keeping up the salubrity and equable climate that is peculiar to that part of the Thames Valley. They serve as wind screens, and act the same part as a breakwater does in subduing the violence of the waves. Remove them to any large extent, and undoubtedly, as a consequence of becoming more wind swept, the temperature will be sensibly lower in winter, and the character of the whole of the district altered. This is a well-known fact, and de-foresting on a large acale has been found to alter the climate of considerable tracts of country very much for the worse; and what is true on a large scale may justly be anticipated to be equally so on a small."

MR. GLADSTONE'S ALLEGED INDIFFERENCE TO SANITARY LEGISLATION.

AN old medical friend of Mr. Gladstone and who had been somewhat of a sanitarian all his life, is wont to complain that he has never been able to enlist the attention of that mind of large and multitudinous interests in questions of sanitary reform—questions of infinitely greater importance to Englishmen than the troubles of Bulgaria and Armenia. This venerable physician has come to the conclusion that sanitation lacks in those "showy" qualities that lead public men to become the champions of subjects that excite the *vox populi*. The best way to get politicians to consider the public health is to educate people up to that point where the latter will begin to insist upon having that theme put as "a plank in every platform." When votes are to be caught by pledges on behalf of sanitary reforms and administrations are turned out for not redeeming such pledges, then will the statesman arise to the needs of the commonwealth, and we will view the upbuilding of a national Department of the Public Health. It is not difficult to imagine how different might have been the position of public medicine before the world if Mr. Gladstone had, in the early part of his career and later, adopted sanitation as one of his war cries. It cannot be said that his attention was not properly called to the subject, for his lively foeman, Disraeli, in the seventies, threw down the challenge in a proposition that speedily sped around the English-speaking world, to the effect that "the first consideration of a minister should be the health of the people."

NEW BATHS AT NEWINGTON.—The public opening of new baths and wash-houses in Manor-place, Walworth-road, took place on Saturday, March 26th, in the presence of a large assemblage, which included Mr. Spokes, L.C.C., Mr. Parker, L.C.C., Mr. Gilbert, L.C.C., the Rev. J. W. Horsley, and numerous representatives of the Newington Vestry and other local bodies. The baths have been erected upon a site secured by the Newington Vestry in 1888, and occupy an area of 4242 square yards. The buildings, which have been erected from the design of Mr. E. B. I'Anson, include a laundry, two swimming baths for men, a swimming bath for women, and various private washing baths. The men's first-class bath has a water area of 120ft. by 40ft., and will hold 157,000 gallons of water. It is to be floored over in the winter, and will be used for public assemblies. The cost has been met by a loan of £41,000, repayable in fifty years.

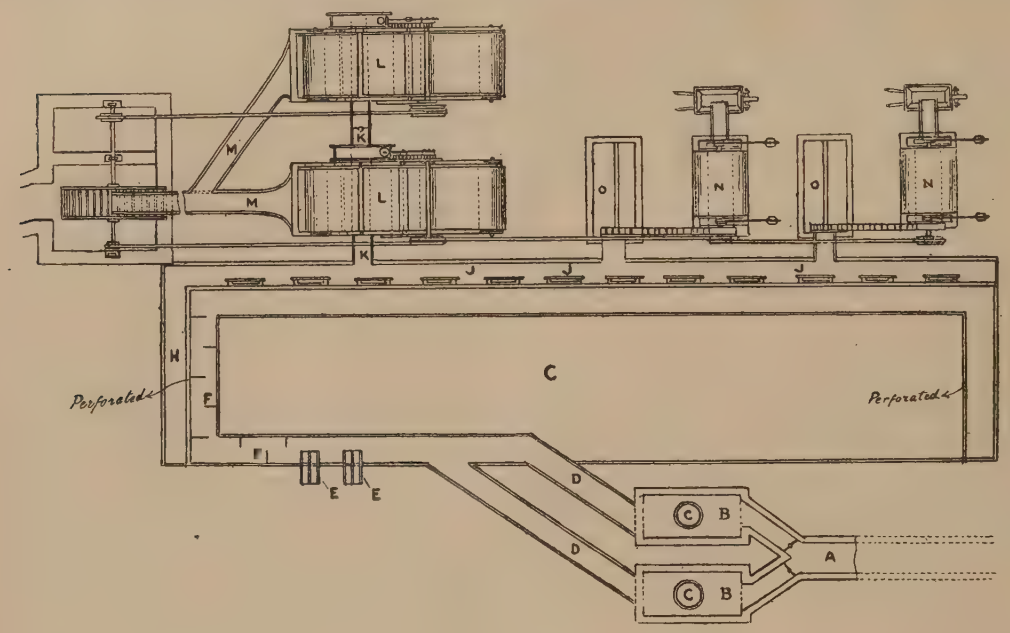
BIRSTALL SEWAGE DISPOSAL WORKS.

FOR the following particulars and accompanying plan of the Birstall sewage works we are indebted to Mr. William Birch, engineer, Lower Broughton, Manchester, the inventor of the system.

The population is about 7000. The district is a woollen manufacturing one, and has also a water-carried system. The sewage is of a very pollutable nature. The plant has been in operation for over three years, therefore the system has proved itself capable of executing its work, and has stood the test and experience which merits it as being a substantial and efficient one.

The flow of sewage is of a fluctuating character, as the district is very hilly, making it very difficult to manage under ordinary circumstances, but in this especial case no trouble is experienced. The sewage on admittance to the works passes by and dissolves a portion of the precipitant—blocks of alumino-ferric, which are placed in nearly perpendicular shoots, with one dipping into the sewage; by this simple arrangement the precipitant applied regulates itself.

After leaving the precipitant the sewage then enters one of the two silt traps (working alternately, to allow each of emptying when necessary), where all road grit and foreign matter is deposited, either by precipitation or screening. The sewage is led from these by a wooden trough in which are placed pieces of timber (bafflers) projecting out from the sides, against which dashes the sewage, breaking the solids up. By now flocculisation has taken place, and the sewage enters the whole width of the cast iron tank (the tank can be constructed of brick) and leaves at the opposite end, from the top, in a more clarified condition, and then passes on to the filter apparatus. During this process the precipitation of the greatest portion of the solids has taken place. The tank, which is continuous, never requires to be let off to extract the sludge, as the same is drawn off by means of ∧-shaped channels, over the whole area of the bottom, leading to valves at one end, or rather, the side of tank—these valves are so constructed that they will not crack during frosty weather. The sludge is directed on leaving the tank by a concrete channel to a sludge well, when it is then raised by a chain elevator to an automatic rotatory sludge press, where all superfluous water is forced out, and the sludge, about the consistency of mortar, is then delivered by a shoot into a receptacle ready for transporting to the land for manuring purposes.



A—Sewage Inlet.
B—Silt Traps.
C—Drain Wells (perforated).
D—Sewage Shoots.
E—Alumino-Ferric Boxes.
F—Bafflers.
G—Semi-ceptic Sludge Trap Settling Tanks (requires no emptying).
H—Overflow.
J—Sludge Outlet Valves.
K—Supernatant Water from Tank to Filtering Machines.
L—Filtering Machines.
M—Filtered Effluents.
N—Automatic Sludge Compressor.
O—Sludge Pits.

It will now be observed that the sewage has been freed of the greatest portion of the solids, which can be taken to the land in a portable condition. By precipitation the solids have been removed, but the clarified sewage yet remains in an unfit condition—it has not yet been sufficiently treated, and is not purified enough to enter any watercourse.

Up to this point it may be safely said that the sewage is the same in all systems of sewage treatment, and the methods by which it is arrived is more or less alike to all; the results obtained being practically the same with the exception of one or two, which claim to have no sludge to deposit, and which are of course being watched with great interest.

The tank for this plant measures 90ft. long, 17ft. 6in. wide, and 6ft. deep. This is an exceptionally small tank for the population; but, by active treatment, aided by the fact of having the same current of stream throughout the whole width over the full length of tank, produced by allowing the water to enter the full width of tank, and by being drawn off at the outlet for the full width, and also by having a slight fall at the inlet, checking the force and giving an almost imperceptible current at an early stage. As duplicate tanks are unnecessary, little space is occupied. There are two sludge-pressing machines, therefore it is no great item for the disposal of sludge.

The next and final treatment of the effluent is by artificial filtration unless afterwards filtered through land. The means of doing this are many, the chief amongst them being through sand, with also some purifying agent; this, like land, needs constant attention and periodical rest, or else it becomes "clogged" up and no longer fit for the work it has to perform. The filters used at these works are not of this description.

In order that a filter may do its work perfectly it must be kept constantly cleaned. As a sand filter cannot provide itself with any provisions for cleaning itself, and as it is not self-sustaining, it is at a great disadvantage compared to a filter whose medium is cloth—as cloth is self-sustaining, and provisions can be made wherewith it can be made to clean itself by motive power; also the impurities can be taken away as fast as they are arrested from the effluent by having the filtering medium (cloth) in constant motion.

The effluent is conveyed from the tank by a wooden trough on to the cloth, where all the remaining solids are arrested by straining action. The cloth, as it becomes loaded with impurities, is gradually working towards the cleansing apparatus, where all the solids are extracted—forced out, by means of an ingenious contrivance, where pressure is applied by springs to a roller moving and working intermittently round a drum over which the cloth travels, when it is subjected afterwards to a washing process. The water used is that of the filtrant water, thus, the filtering medium is kept constantly cleaned with motive power, instead of hand labour as in filter beds. The effluent on leaving the cloth passes over the surface of a series of wooden rollers—forming a bottom upon which the cloth travels—in a thin film, absorbing the oxygen of the atmosphere, hence the oxidisation and aëration of the effluent has taken place, which is the last and final stage for the purification of the sewage.

The waste water resulting from the washing process of the filter machines, of which there are two, and the superfluous water from the sludge presses is gravitated back to the tank for retreatment. The filter machines each occupy a space of 23ft. by 8ft., and the sludge presses each occupy 6 square feet. The motive power to drive the plant is derived from the filtrant water passing over a water-wheel, therefore the plant may be safely described as automatic. The works are situated within the heart of the district, bounded on two sides by the principal streets, and surrounded by houses—thus testifying to the efficiency of its operation.

Sanitary Inspectors' Associations.

LONDON.

THE ordinary monthly meeting of the members of the Sanitary Inspectors' Association was held on Saturday, at the Carpenters' Hall, London Wall, E.C. Mr. T. G. Dee, Westminster, the Chairman of the Council, presided, and there was a good attendance of members, including Messrs. C. W. Raymond, I. Young, H. Alexander, W. W. West, Potter, S. C. Legg, Barth, Pettit, Ashdown, Thomas, Chapman, Duck, Jordan, Bagshaw, &c., and Mr. E. Tidman, C.E., the Hon. Secretary. A number of new members having been elected and general business transacted,

The CHAIRMAN read a paper on "Sanitation in the Homes of the Working Classes," by Mr. T. J. Moss Flower, C.E., F.G.S., of the Western Branch, he being unavoidably absent. This was, he said, a subject more or less interesting to Sanitary Inspectors as well as to the public at large, particularly to those engaged in the application of the principle shadowed forth in the laws bearing upon sanitation in dwellings. The term "shadowed forth" was used advisedly, because in many instances, the intention of the legislators could not be successfully determined. The sanitary condition of the homes of the working classes was a matter receiving much attention in this country, and necessarily so, because it is a matter which greatly concerns the well-being of the nation, looked at from every point of view. Sanitary Inspectors were fully alive to the enormity of the degradation, misery, sickness, and death occasioned by the insanitary condition of working-class dwellings in this country—a country characterised as being "fair and beautiful," and "the home of the brave and free." The scope of the paper was to define some of the defects existing at the present time, to discuss a few of the causes, and to make some suggestions as to the possibilities of bringing about a better state of things. Who are the working classes? It was difficult, he thought, to define that class, since all persons whose existence depends upon their own efforts belonged to it, and it included not only the field labourer, the docker, and artisan, but also the merchant and the professional. But for the purposes of the paper the working classes might be regarded as those who gain their livelihood by manual labour, and whose income averages anything up to 32s. per week. The maximum rent they could pay was from 4s. to 6s. 6d. per week. Now, cottages they occupied in rural districts were generally more or less insanitary, being frequently thatched, without drainage or proper water supply. Large houses of the tenement type in towns were frequently found to be in a deplorable condition. Then there were the dirty little houses to be found off fine business thoroughfares—houses possessing two or three rooms, without a backlet or open space; houses built back to back, small houses in narrow streets; there were also the houses of the barrack or flat type, which, although a distinct improvement, were by no means ideal; yet they were the means to crowd upon a small area a large number of human beings. This was not necessary when so much land was available on the outskirts of the towns, provided cheap

and easy means of communication were granted. Overcrowding on small areas was to be attributed to the defects in the land laws, and until Parliament insisted upon the land bearing its proper share of taxation so long would they have to look upon this crowding. The building bye-laws in towns were not nearly severe enough in many respects, and in some cases they were practically a dead letter. This crowding upon area conduces to a low condition of life, a low standard of morality, and a high rate of mortality, helping to rob life of all its natural charm. Rents in the centre of large towns were so high that the working classes were driven to take what was on offer, with the inevitable results. For these people something would have to be done in the way of clearance of unhealthy areas and the erection of suitable dwellings. But the clearing of an insanitary area more often than not displaced more people than could be replaced. What then was to be done with those for whom no provision had been made? The only problem was to erect suitable dwellings on the outskirts of the towns and provide cheap travelling facilities. The insanitary evils most common in the homes of the working classes were overcrowding, defective roofs, gulleys and spouts, defective drains—coked, cracked, leaky, untrapped, unventilated, defective w.c.'s, unflushed, unventilated, in bad positions ; absence of ventilation, dirty walls, crumbling ceilings, absence of fireplaces, several thicknesses of dirty paper on the walls, want of lime washing, dampness from soft bricks and mortar, absence of damp course under walls and beneath lowest timber, site not covered with concrete, space not ventilated under floor, woodwork decaying from want of paint. All these evils were often aggravated by the site of the house being below flood level, or the house beiug built on hollows previously filled with house refuse. Overcrowding was one of the greatest difficulties of the Sanitary Inspector, for their poverty could not be removed. This evil existed not only in large towns but also in rural districts where there was absolutely no excuse for it. In watering places during the summer the homes of the working classes were frightfully overcrowded owing to visitors being lodged. The whole list was capped by the absence of legislation calculated to successfully deal with the proper housing of the working classes, by the Government and municipalities. A great deal of the responsibility rested with the Sanitary Authority, who gave to one Inspector work enough for half a dozen men ; not only so, but a large proportion of that one man's work was quite outside the duties of a Sanitary Inspector. The wealthy and the well-to-do could look after themselves, but the working classes who had an equal right to have their houses regularly inspected, were neglected. Further than this, the fact that the members of the local boards were too often interested in not having sanitary work properly carried out, had to be taken into account, and if a Sanitary Inspector was zealous he was liable to be turned out. The property owners were largely represented on the Local Authorities, and they could render an Inspector's life so unpleasant that he would prefer to resign at a great sacrifice, rather than remain and be afraid to do his duty properly. Parliament was to blame for this, and therefore the Association asked for a secure tenure of office for Sanitary Inspectors, who would use the power given to them only for the good of the many in a just and fair spirit. But it was not to be thought either that the working classes were not themselves in some instances to blame for the insanitary condition of their homes. In such cases the evils were difficult to deal with, but improvement in this respect was to be expected in the future from a course of hygiene being made a part of every school curriculum. Landlords often would do nothing for their tenants, and while houses were in agents' hands or changing owners it was most difficult to get nuisances due to structural defects abated. An amendment of the law in this respect was urgently needed, fines for non-observance of the law increased with power to the magistrates to send offenders to prison. Magistrates, too, were often unable to look at sanitary requirements with a broad mind, and dealt leniently with property owners. It was the duty of the Sanitary Inspector in carrying out his noble work to see that those who could not well help themselves should receive his willing and ready assistance. Those who preached the gospel of health should live the gospel of health, and should be placed in such a position that they can conscientiously and fearlessly do their duty to all men without fear of tyranny or the loss of the means of existence. The nation which did not pay proper attention to the improvement of the sanitary condition under which the working classes live, must eventually make way for other nations that do, and while this country was by no means in the rear in this important national work, there was much which still required to be done.

Mr. W. W. WEST (Walthamstow) moved a hearty vote of thanks to Mr. Moss Flower for his paper, and this was seconded by Mr. DUCK (Plumstead).

Messrs. ALEXANDER, YOUNG, THOMAS, CHAPMAN, and the CHAIRMAN took part in the discussion which followed, and the vote of thanks was heartily accorded.

The members' private conference was then held, and the proceedings ended with the usual compliment to the Chairman.

WHAT CITY MEN BREATHE.—Some interesting statistics relating to the presence of dust and bacteria in London air have been reproduced in the first number of the "Transactions" of the British Institute of Preventive Medicine. From experiments made, it appears that in a suburb the dust particles numbered 20,000 per cubic centimetre in the open air, and 44,000 in a quiet room ; in the City, on the other hand, the totals per cubic centimetre were 500,000 when taken from a roof, 300,000 in a yard, and about 400,000 in a room. In the City the dust contamination was proved to be 900 per cent. greater than in the suburbs, which fact is in accord with the general experience that fogs are both more dense and more frequent over the centre than in the outskirts of the City. Although dust is the great carrier of micro-organisms, the proportion of the one to the other was found to be not higher than one organism to 38,000,000 particles. Calculating 100 organisms per cubic metre, a man in the course of his three score years and ten would inspire about 25,000,000 microbes, which is about the number contained in half-a-pint of milk.

Institute of Sanitary Engineers

THE SANITARY ADMINISTRATION OF BELFAST.

(*Continued from page* 343.)

It is quite clear that the poorer classes, whatever their employment, are more crowded together in their dwelling-houses and sleeping rooms, as well as in their work places, than others, and are therefore more exposed to the infection of this disease. From the same causes they are more likely to be debilitated by the want of good air, and therefore in a more favourable condition for yielding to infection. The circumstances of the case render it not so easy, however, to provide a remedy. Any we seek for must in part be found in improved action on the part of the Authorities, but in the main from improved intelligence on the part of those who suffer.

First of all, then, what regulations can be made which will protect the poor from this scourge? The regulation of work places must, after all, be partly conditioned by what will allow them to be carried on at a reasonable profit, otherwise the livelihood of the workers will cease. Short of this limit, however, ample provision for ventilation must always be insisted upon, and the use of warmed fresh air might be more often inculcated, if not compelled, than is the case. It is not the people who live in the open air, however much their exposure, who suffer from "colds," or who die of consumption. The butcher, the policeman, the bricklayer in his shirt sleeves upon the scaffold, are not consumptives. Neither is the sailor, who for days together has hardly a dry thread upon him; or yet the labourer in the fields—he may be bent double with rheumatism before he is sixty, but that is not consumption. It is the tailor in his warm and sheltered workroom, or the girl in the hot spinning mill or sewing-room, who wastes away with this disease.

But the chief remedy must come from the enlightenment of the people themselves. Every modern military bureau has now an intelligence department; such a department as, had England possessed one at the time of the Crimean War, would have informed the Generals that in the Crimea the winter usually set in early and was very severe, and that would have seen that the necessary precautions against this were taken in time. Why might not every Town Council—and County Council, indeed—also have an intelligence department, whose duty it should be to provide for the health education of the masses?

No doubt the enforcement of sanitary bye-laws is in itself a sort of education for the people, but it is slow and very imperfect in its operation. What is wanted is that every National School teacher should be acquainted with at least the elements of hygiene, and should be able to impart to their scholars simple lessons often repeated and enforced by example as well as precept, because, unfortunately, the great bulk of our elementary education seems to be so given that it remains something quite apart from and totally unconnected with the daily life of those taught. There is a very great mass of information upon sanitary matters, upon the laws of health in general, among the members of any Public Health Department, which should be freely placed at the service of the people. More especially might a series of simple health leaflets, couched in the plainest and most intelligible language, and printed in large type, be distributed broadcast amongst the working classes, and that not as a mere isolated effort only, but regularly and often repeated. Do we not all know as a fact, that, except perhaps in some moment of temporary panic at the outbreak of a great epidemic, not alone the poorer, but every class of the electors, care less than nothing for sanitary matters? The elections hinge upon a man's politics, upon his religion, upon any consideration rather than whether he is an intelligent sanitary reformer. No such qualification would weigh in favour of a man, however good and able, if he had not also the support of some powerful political organisation; if he possesses that, the want of the other qualification would matter but little to his chances of success. Several years ago a "Health Society" was started in Belfast under the most eminent, scientific and social patronage. It ran for about twelve months, and then suddenly ceased, certainly for anything but the alleged reason that it had accomplished its work. While in existence several health lectures were delivered under its auspices, among others, one by the Medical Officer of Health for the city. What I would contend for is that in every well-regulated community the Public Health Department should be a permanent health society, independent of fashionable caprice, and responsible to the whole constituency, but that will never be until municipal constituencies are lifted up out of the miserable slough of party politics.

There is a topic which has not yet been touched upon, but which to all child-lovers should be of surpassing interest. This is infant mortality. It is rather surprising that, considering the position of Belfast as a great manufacturing centre, it should come out under this head as creditably as it does. For the year 1896, the last to which I have access, the mortality per thousand births of children under one year old in Belfast was 147, for eight other large towns during the same period it was greater, viz., Dublin, Leeds, Liverpool, Manchester, Blackburn, Oldham, Birmingham, and Preston; Birmingham coming out worst with 197 per thousand. Yet Birmingham has always been taken as a model city in municipal affairs. The consideration of these figures leaves it rather difficult to decide exactly where the cause lies. The employment of women in Belfast in factories and work places of one sort and another is exceptionally large, and to the employment of mothers away from their homes infant mortality has generally been ascribed. Possibly an explanation may in the case of Belfast be found in the fact that there is here employment of many varied sorts, shipyards, and their concomitant works, as well as spinning, weaving, box-making, &c. &c., so that it may to a larger extent than in some other places have resulted, that while every other member, male and female, were employed the actual mothers could be left free to remain at home.

There can be no doubt, however, that in the case of infant mortality it is due to the ignorance or the indifference of the mothers themselves. The remedy must come from the improved mental and moral condition of these. But surely, if we

are to be governed at all, these matters must occupy the attention of our rulers. Papers like this deal not merely with the law and its administration as it *is*, but as it *ought to be*. The suggestions made may not always be feasible as the law now stands, but they are suggestions for a brighter future.

It was said to be the boast of a great Roman ruler, that he "found Rome of brick and left it of marble." Referring to this, a great English orator of the present century, speaking of the reform of the law, said, that he hoped that some English reformer might be able to boast, that he "found law dear, but left it cheap;" possibly rather a questionable boast, because law at its cheapest is apt to be found in the end an expensive privilege. But the boast will be without alloy if in some year—let us devoutly hope in the early future—some, or many, legislators may say that they found the health of the people bad, and the death-rate high, but that they left it low, and the health of the people good, and as a consequence thereof, the people happy, contented, and leading good and useful lives; the children happy and smiling, the youths full of exuberant life, those of middle age the masters of their work, and more than the rivals of foreign nations, and old age happy and contented, because healthy and without any but inevitable decay. To all these wishes let us devoutly say, Amen!

DISCUSSION.

Mr. WELLS proposed that a hearty vote of thanks be conveyed to Mr. Lockwood for his interesting paper. He had treated the subject in a very exhaustive way, and their thanks were due to him for the trouble he had taken in dealing with it. One thing he could hardly understand in the paper was why a large town like Belfast permitted large deposits of street refuse to be placed on sites near the town, which were ultimately intended to be built upon. He did not know what precautions were taken under the bye-laws of the city in regard to building on such sites, but it was a dangerous thing to build on a site 10ft. deep in house refuse.

The CHAIRMAN said he thought the paper said after seven years.

Mr. WELLS replied that that was not sufficient time to elapse before the land was built upon. He supposed the same bye-laws were in force in Belfast as in London. But even then he thought it rather a dangerous proceeding. He thought a dust destructor was a far better way of dealing with refuse.

Mr. DOVE seconded the vote of thanks, and said that Mr. Lockwood had taken very great trouble to bring the whole of the sanitary matters in Belfast before their notice. It appeared to him that not only did the Belfast Authorities allow the deposits of refuse to be placed on waste land, but that they were raising a bank on the side of the river, which, in his opinion, was far worse than placing the refuse upon waste land. Some years ago he knew a very large gravel pit. It was about 25ft. deep, and extended over two acres of land. It was a portion of a brickfield. It became a common shoot, was ultimately filled up, and had now for years been built upon. He happened to know some people who resided in those houses. Some of his friends went there when the houses were just finished and others at a later period, but from the first to the last there was always a complaint about dampness. Of course cracks were numerous, and he believed the whole portion of the brickfield had a bad reputation for sore throats.

Mr. RAYNER, referring to the question of notification of diseases, said that he had noticed the poorer classes generally had a dread of hospitals, and would not go to them when there was a case of infectious disease in the house. They always tried to keep the infectious person at home, and by that means many other persons in the neighbourhood had the disease communicated to them. He noticed in Sutton there had been one or two such cases, and the Sanitary Inspector had had to deal with them rather strictly. He thought the poorer classes required to be educated on the matter. When they educated them in sanitary laws they would see the benefit to be derived from taking the patient direct to the hospital, and so be the means of stopping the spread of the disease.

The CHAIRMAN said that had time permitted he should have joined issue with Mr. Lockwood on his contention with regard to the conversion of cottage property to business premises. In the year-book of the Belfast Corporation he was very much struck in the progress that had been made there. He was in Belfast some fourteen or fifteen years ago and was very much impressed with the go-ahead way of the place, and the way in which the city was laid out as regarded open spaces. Belfast had only been incorporated since 1841, and at that time the population was 75,000. In 1891 it had risen to 255,000, in 1896 to 305,000, and they might safely put it now at 325,000. Apart from Johannesburg and Klondyke, he did not believe there was any town which had increased at the rate of Belfast. At the present time there were seventy-five sets of building plans presented per week to the Corporation, so that what with the progress being made on the old property before the foundation of the Corporation, he thought their sympathies might go out to those who administered the Health Acts and bye-laws under those Acts.

The vote of thanks was unanimously passed, and a similar compliment having been accorded the Chairman, the meeting dispersed.

The following gentlemen were elected as members by the Governing Body of the Institute of Sanitary Engineers at the meeting held on the 24th ult.:—

FELLOWS:—Aburrow, Charles, Assoc. M. Inst. C.E., Town Engineer, Johannesburg, South Africa; Adams, Stephen Isaac, Mem. San. Inst., Southend; Brook, James Riddell, Wimbledon; Hainsworth, Marshall, Mem. Assoc. Municipal and County Engineers, Teddington; Harlock, Harold, Assoc. M. Inst. C.E., Mem. Assoc. Municipal and County Engineers, Southend; Jones, Edwin John, Architect and Surveyor, Cardiff; Leed, James Constable, Cambridge; Matthews, James Newsome, A.M. Inst. C.E., Doncaster; Morris, Adam, Assoc. San. Inst., St. Boswells, N.B.; McLean, Hugh, Nottingham; Unwin, William Thomas, March; Stow, John Freebairn, Bridlington.

ASSOCIATES:—Bridge, Thomas Henry, West Bromwich; Chown, William Henry, Lympstone; Jaques, Henry Lea, Assoc. San. Inst., Moston, Manchester; Mansfield, William Joseph, Nottingham; Markham, William Ephraim, Assoc. San. Inst., London; Mankin, Hender Goman, R.P.C., London; Nicoll, Walter Ramsey, R.P.C., Sanitary Association of Scotland, Perth; Streather, Edward, Assoc. San. Inst., London; Sturch, Wilmer, London; Webb, George Stephen, Sutton.

General News.

HOME.

TWEEDMOUTH.—The boring for water is to be continued.

INGATESTONE.—The cost of the proposed water supply, exclusive of the land, is estimated at £750.

EASTBOURNE.—The plans for the proposed improvement of the Princess Alice Hospital have been approved by the Joint Committee.

MEDWAY.—Mr. G. E. Bond, architect, has estimated the cost for the new hospital at £4300. The plans have been submitted to the Guardians.

STRATTON.—The District Council has decided to proceed with the Wrasford Moor scheme of water supply for Stratton and Bude. The estimated cost is £9000.

WEST LANCASHIRE. — The Urban District Council has decided to advertise for tenders for the piping for the supply of water to Melling from the Kirkby and Knowsley pumping stations.

SOUTHWARK.—The Vestry has decided to apply to the London County Council for a loan of £3900 to defray the cost of the construction of underground conveniences in Old Kent-road and Borough-road.

WOOLWICH.—The Local Board has decided to make application to the Local Government Board to sanction a loan of £2500 for the purpose of erecting a new mortuary, post-mortem room, and shelter in Sun-street.

HEYSHAM.—At the annual parish meeting, reference was made to the arrangement with the Lancaster Corporation to supply Heysham with water, the cost of the scheme being estimated at between £3000 and £4000.

LANCASTER. — A conference of representatives of the Lancaster, Garstang, and Morecambe District Councils was held at Lancaster recently to discuss the proposal to erect small-pox and isolation hospitals for the combined districts.

ADERDEEN.—The Public Health Sub-Committee of Aberdeen district of the County Council has agreed to co-operate with the Town Conncil in the arrangements for the employment of Professor Hamilton as bacteriological examiner in cases of infectious diseases.

KEIGHLEY.—Owing to a fresh epidemic of diphtheria the Medical Officer has closed the infant and junior departments of the Holycroft Board School. Similar action was taken a few weeks ago with satisfactory results, but since the schools have been re-opened about a dozen more cases of the disease have been reported.

CHISWICK.—The annual report of Dr. Dodsworth, the Medical Officer of Health, has just been compiled for the District Council, and contains a mass of interesting statements and statistics, showing great improvement in the health of the parish. The vital statistics show a rise in the birth-rate, being about the average for the past ten years. The death-rate was one of the lowest on record, while the rate from zymotic disease was considerably less than that of the previous year. The year was, on the whole, a healthy one.

ROTHERHITHE.—Improvements are suggested for the swimming baths.

WROTHAM.—A Local Government Board inquiry has been held with reference to the provision of a water scheme for the district.

BURNLEY.—The Local Government Board has intimated to the District Council that under certain conditions it would be prepared to approve of the proposed scheme for providing a supply of water to Foulridge.

MIDDLESEX.—The Middlesex County Surveyor, Mr. F. H. Pownall, has resigned his post, and has been appointed consulting surveyor at a salary of £200 a year. The former office is now open, and the salary is to be £700 a year, rising to £850. There will be a deputy and two assistants at salaries of £250 a year, rising to £350.

DORSET.—With reference to the water supply of Maiden Newton, the Sanitary Committee recently reported that it was still in communication with the Governors of the Dorchester Grammar School as to the site of the reservoir. It had also received an offer from Lord Wynford of a site adjoining the previous site, and was considering which plan would be the more feasible.

ABERDEEN.—The report by Mr. Dyack, Burgh Surveyor, on the proposed public slaughter-house has been issued to the Committee in charge of the scheme. Mr. Dyack discusses the sites at Central Park, Hayton-road and Cattofield, and has also, at the Committee's request, prepared a modified plan of a building at Central Park. The estimates of proposals vary from £30,000 to £60,000.

NORTHAM.—The Urban District Water Bill, which has been read a second time, recently came before Mr. J. W. Lowther, chairman of Ways and Means. The object is to authorise the Urban District Council of Northam to construct waterworks for the supply of its district, the estimated cost of the undertaking being £27,000. The Bill, with amendments, was formally reported for third reading.

CHINLEY.—At a recent meeting of the ratepayers of Chinley, Bugsworth, and Browside, held to consider the proposed scheme of water supply for New Smithy and Chapel Milton, a small portion of the township, it was stated that the estimated cost of the scheme, as prepared by Messrs. Sterling and Swann, by direction of the Chapel-en-le-Frith Rural District Council, was £2500, exclusive of engineering and legal expenses. The proceedings terminated with a resolution requesting the District Council to convey the water all over Chinley and Bugsworth, in case the people have to pay.

DUNDEE. — In accordance with instructions given, Sir Thomas Thornton, Town Clerk, has prepared a report on the subject of the terms on which water is supplied by the Water Authorities of several towns in Scotland for sanitary and other purposes. The question was raised at the last meeting of the Town Council in connection with the supply of water to the harbour, and at the same time it was suggested that the Sanitary Department of Dundee was not paying its full share that the supply of water required. The report was submitted to a recent meeting of the Sanitary Committee of the Town Council, when it was agreed that the matter should be fully considered in detail.

BRADFORD-ON-AVON.—At the last District Council meeting it was decided to thoroughly overhaul the engine at the waterworks, and also to take up the remaining £2500 of the loan of £5000 for sewerage purposes.

ABROAD.

ROUMANIA.—At various dates between April 7th and May 11th, there will be adjudicated in this country tenders for the construction of barracks, slaughter-houses, &c., amounting to £120,000.

PERU.—The following Order has been issued by the Government of Peru:—"That a period of six months from January 15th be allowed steam vessels calling at ports in Peru to be fitted with disinfecting stoves. After the expiration of this time (say, 15th July, 1898) no steam vessel will be allowed to anchor in a port in Peru unless so fitted."

SYDNEY.—One of the most distant of the series of dams which are required to ensure for Sydney a constant supply of water had been washed away. The dam is that known as the Cataract dam, was about 500ft. across, rose to a height of 10ft. above the bed of the river, and was 14ft. wide at the base. The dam was constructed of concrete and masonry, and was generally regarded as a substantial work. It was stated that there was no occasion for any alarm being felt by the citizens of the metropolis or the residents of other places at present supplied with water from the Nepean scheme, because there is in the Prospect reservoir about 18 months' supply of water. The water is now running over the weir at Prospect, and the reservoir contains eleven thousand million gallons of water. The present rate of consumption for Sydney and suburbs is 20 million gallons per diem, and there being in the reservoir seven thousand million gallons of water which would be available for gravitation, it would take 350 days to consume this volume of water at the ordinary rate of consumption.

Personal.

MR. W. WYNNE has been appointed Medica Officer for number two district of Rye union.

MR. E. KENNINGTON has been appointed Medical Officer for number eight district of Basingstoke.

JOHN HENRY HOBLING, L.S.A. (Lond.), has been appointed Medical Officer for the Bideford rural district.

A. H. WHICHER, M.R.C.S., has been reappointed Medical Officer of Health for the Midsomer Norton urban District.

MR. C. R. SPENCER has been appointed Surveyor for the Belper urban district, at a salary of £150 per annum.

R. DAVEY BOASE, L.R.C.P., M.R.C.S., has been re-elected Medical Officer for the Penzance Port Sanitary Authority.

THE salary of Mr. T. Charles, Engineer and Surveyor for the urban district of Harrow, has been increased by £50 per annum.

MR. G. GREEN, late Assistant Surveyor to the Islington Vestry, has been appointed Surveyor to the St. Martin's-in-the-Fields Vestry.

THE Local Government Board has sanctioned the appointment of Dr. Pratt as Medical Officer for the urban district of Wiveliscombe.

MR. J. PAGET WADDINGTON, of Whitechapel, has been elected Surveyor for the Marylebone Vestry, in room of Mr. Tomkins, retired.

DR. CALEB J. POWELL has been appointed Medical Officer for the North Dublin union workhouse in room of Dr. Minehin, retired.

CHARLES J. MYERS, M.R.C.S., L.S.A., has been appointed Medical Officer of Health for the Louth rural district, vice R. Domenichetti, resigned.

ARTHUR D. FORBES, M.B. (Aberd.), has been appointed Medical Officer for the seventh sanitary district (Horsmonden) of the Tonbridge Union.

MR. E. W. CODE, of the Borough Surveyor's office, Tiverton, has been appointed District Engineer under the Ceylon Public Works Department.

J. MCKENNA, M.D., Ch.M. (Irel.), has been appointed a Public Vaccinator for Shepperton, Victoria, Australia, vice J. W. Harbison, resigned.

CHARLES W. VICKERS, M.R.C.S., L.R.C.P. (Edin.), L.S.A., D.P.H. (Lond.), has been reappointed Medical Officer of Health for Paignton, Devon.

W. KING BULLMORE, M.D., St. And., M.R.C.S, L.S.A., has been re-appointed Medical Officer of Health for the Falmouth and Truro Port Sanitary Authority.

J. W. COX, M.B., Ch.M. (Edin.), has been appointed a Government Medical Officer and Vaccinator for the district of Nymagee, New South Wales, vice H. R. H. Peare.

MR. F. A CLARKE, Plymouth, has been elected Engineer and Surveyor for the rural district of Plympton, at a salary of £150 per annum, and a commission of 2½ per cent. on all works executed.

MR. R. S. W. PERKINS, chief assistant to Mr. R. J. Thomas, County Surveyor of Buckinghamshire, has been selected by the Monmouthshire County Council for the appointment of District Main Road Surveyor under Mr. William Tanner, the County Surveyor.

Sewerage Schemes.

[TO MUNICIPAL ENGINEERS AND SURVEYORS.—The Editor will be pleased to receive items for publication relating to sewerage schemes projected or inaugurated, together with explanatory diagrams or photographs. The former should be drawn and lettered in black ink.]

THE Urban District Council of Chesterton has borrowed £650 for sewerage works.

THE Local Government Board has sanctioned the borrowing of £300 for the Ormskirk end of Bickerstaff sewerage, West Lancashire.

THE Colwall Parochial Committee has resolved to accept Mr. Clarson's estimates of twelve guineas to make plans, sections, specifications, and estimates for the Wyche sewerage scheme.

THE Local Government Board has sanctioned the borrowing of £1000 for sewerage works at Bridlington.

A LOCAL inquiry has been held at Barnstaple with reference to the Town Council's application to borrow £3300 for sewerage and for a swing-bridge.

THE Chesterfield District Council has decided to call in Mr. Walker, of Nottingham, to prepare a sewage disposal scheme for the consideration of the Council.

AN arrangement between the Leatherhead and Ashtead Councils regarding the disposal of sewage as proposed by the Committee has been adopted by the latter Council.

THE Wellington Urban District Council has authorised the Drainage Committee to make further inquiry with a view to experimental works for the treatment of sewage.

A SPECIAL meeting of the Isle of Thanet Rural District Council was held recently in connection with the Minster drainage scheme. Mr. Bailey Denton was appointed engineer to the scheme.

THE Corporation of Wolverhampton has decided to abolish the catchpits on the old sewers, and to carry out other improvements at an estimated cost of £4560. The borough surveyor has also been instructed to make tests of various sewer flushing and ventilating apparatus.

ON Wednesday, the 30th ult., the Aberfeldy sewage purification works were formerly opened by Mr. Wm. Dunn, factor to the Marquis of Breadalbane. Mr. Copland, C.E., Glasgow, the engineer of the scheme, briefly described the works, and explained the system of purification.

A DEPUTATION, consisting of Mr. J. M'Hutcheon Dobbie, convener of the Lasswade District Committee of the County Council of Mid-Lothian; Mr. Charles Cowan, Valleyfield; Provost Liddell, Bailie Lucas, and Mr. Paul Goudie, Sanitary Inspector, Dalkeith, visited on Friday last the Glasgow Corporation sewage works, in view of the expected necessity for an extensive drainage scheme for the Esk Valley district.

THE Derbyshire County Council, which has long been threatening the Corporation of Derby with proceedings in respect of their pollution of the River Derwent, now signifies its intention of going into Court next May. The Corporation, while striving to remedy the nuisance, by the adoption of some effective scheme of sewage disposal, is anxious to avoid litigation, and at a private meeting it was decided to request the Mayor to wait upon Lord Waterpark (Chairman of the Public Health Committee of the County Council) with a view to securing an amicable arrangement.

A LOCAL inquiry is to be held at Newmarket into the Urban District Council's application for permission to borrow £45,000 for main drainage works.

A LOCAL Government Board inquiry has been held at Bexhill into the application of the District Council to borrow £4500 for the purpose of drainage at Little Common.

A LOCAL Government Board inquiry was held at Edmonton last week into the applications of the District Council for sanction to borrow several sums, including £4571 for works of sewerage.

THE Leyland Urban District Council has obtained the sanction of the Local Government Board to a loan of £5200 for the purpose of executing additional works of sewerage and sewage disposal, and their engineer, Mr. Wrennall, has been instructed to take the requisite steps for the execution thereof.

AT a meeting of the Rural District Council of Keighley, the question of Morton sewerage and sewage disposal was under discussion. It was suggested that the Council should apply for a loan of £4000. Neither of the Morton representatives would move to that effect. It was stated that the Council was under a binding contract to take the land. Finally it was decided to apply to the Public Loan Commissioners for £4000.

A LOCAL Government Board inquiry was held at York during last month in reference to the application of the City Council for sanction to the borrowing of £23,000 for sewerage purposes, as authorised by the Council. The application for power to borrow £2500 for the experimental septic tanks was opposed by Lord Wenlock and the fishery tenants below Naburn Locks. The Yorkshire Fishery Board and the West Riding of Yorkshire Rivers Board were also represented.

THE Public Works Committee of Balsall Heath Council reports that plans have been submitted for the laying out of the estates of Messrs. Smith-Ryland and J. R. Turner, lying between Balsall Heath-road and Edgbaston-road, and it is found that the sewers in the district are too shallow to effectually drain the area. It is also found that owing to the development of property in this part of Balsall Heath, the sewers which were constructed by the late Local Board are already overcharged, and that the sewers in Court-road and Clevedon-road are in an unsatisfactory condition. Under these circumstances it has been necessary to devise a scheme of main drainage for the low-lying portion of Balsall Heath, between Balsall Heath-road and Edgbaston-road. The City Surveyor has prepared a scheme by means of which the whole of this area can be effectually and satisfactorily drained, utilising the sewer in Alexandra-road, which is of adequate dimensions for the purpose.

THE Local Government Board has rejected the sewerage and sewage disposal scheme which was the subject of the recent inquiry at Warminster.

A SPECIAL meeting of the Monmouth Town Council was held recently, when the engineer, Mr. Lailey, was present by request, and was asked to explain how his original estimate for the drainage was several thousands of pounds below the actual cost. Mr. Lailey attributed some of the extras to the purchase of timber, cement, &c., the necessity for which was not discovered until after the excavations were commenced. Mr. Lailey submitted a new report on the drainage, which was complained of by the Council. It was eventually agreed to ask for powers to borrow £10,000 more to complete the work.

A MEETING of property owners and ratepayers, convened by a Committee appointed two years ago to watch the interests of the town in regard to the drainage area question, was held at Shifnal last week. Mr. J. R. Howard McLean presided, and said his views were in direct opposition to the formation of the proposed drainage area for Shifnal, or the formation of any area other than that including the whole parish. In the chairman's opinion, the water and drainage schemes for Shifnal could not be carried out for less than £9000. The number of the Committee was increased, their duty being to oppose the formation of the proposed area.

Lighting.

THE Enfield Gas Company's Bill has passed through Committee without opposition.

THE undertaking of the Kingston-upon-Hull Gas Company has been taken over by the Corporation, the price paid for it being £92,500.

THE York Corporation has come to an agreement with the local Gas Company, and as a result all opposition to the Parliamentary Bill promoted by the latter has been withdrawn.

A LOCAL Government Board inquiry has been held at Conway into an application of the Town Council to borrow £1500 for new municipal buildings, and £310 for gasworks purposes.

SWANSEA Corporation has under consideration a report by Mr. Manville on a scheme for electric lighting. The capital expenditure on this scheme Mr. Manville fixes, after adding 7½ per cent. for contingencies, engineering, &c., at £35,936. In his estimate of the revenue derivable he gives 15,700 8-candle power lamps for private lighting, which would, at 4½d. per unit, bring in £4444, whilst the public lighting would bring in £733, making a total of £5177. The cost of maintenance he averages at 3·05d. per unit, which gives a surplus of ·77d. per unit, or a total of £1052.

MR. PREECE is to be asked to enlarge the proposed boiler-house in connection with the electric lighting works at Wimbledon, so as to provide room for an additional boiler for a dust destructor, and to prepare plans and estimates for the latter.

A SPECIAL meeting of the Sheffield City Council is to be held on April 13th, for the purpose of approving of the applications to Parliament for a local and personal Act "to confirm an agreement for the purchase of the undertaking of the Sheffield Electric Light and Power Company (Limited) by the Corporation of Sheffield, and to confer borrowing powers and other powers on the said Corporation."

THE Electric Lighting Committee of the Edinburgh Town Council has resolved to recommend that the charges for energy from Whit-Sunday next should be 3½d. per unit with the ordinary discount, for each public lamp £14 per annum, and for motor power 1½d. per unit. The Committee has also agreed to recommend that the salary of the resident electrical engineer should be increased from £500 to £600 a year.

AT last Friday's meeting of the Oldbury District Council the Gas Committee reported having fully discussed the question of electric lighting, and the application to the Board of Trade for Provisional Orders both by the Council and the Midland Electric Corporation, and recommended that, subject to the approval of the Board of Trade, and providing satisfactory terms in all respects to the Council can be arranged, and the opposition by the Midland Corporation to the order of the Council be withdrawn. The Council discussed the matter in committee, but the idea is to keep control of the public lighting of the town, and to make arrangements for the Midland Corporation to supply the Council in bulk at a reduced rate, but to supply the manufacturers on their own account.

AT a meeting of the Gas and Electricity Supply Committee of the Bradford City Council last Friday the Mayor (Mr. T. Speight) presented an interesting report containing the result of the observations of a deputation which recently visited the Continent for the purpose of inquiring into the various systems of electric lighting and traction. The deputation visited Brussels, Hamburg, Berlin, Dresden, and Leipzic, the electric equipment of which towns was described at considerable length. It appeared that at Leipzic they inspected the works of Messrs. Körting and Mathieson, arc lamp makers, where special inquiries were made with a view to improving the public lighting arrangements of Frizinghall and Heaton by means of small arc lamps instead of incandescent lamps. The generating stations were very much larger and finer than anything to be seen in this country, and there could be no question but that, instead of making undue haste in the matter of electric traction for lighting, Bradford was in each of these instances considerably behind the development which had already taken place in each of the towns which were visited.

Law Cases.

NOVEL SANITARY PROSECUTION AT GOVAN.

A CHIMNEY sweeper named William Docherty was charged at Govan Police-court with having in his house permitted the body of his mother, who died of enteric fever, to be "waked" previous to burial. He pleaded not guilty.

From the evidence it seemed that the Sanitary Authorities had been notified of the woman's death, and in the course of the afternoon two assistants warned the accused that he would be prosecuted if he allowed a "wake" to be held, as it was illegal under the new Public Health Act. They again visited the house shortly before midnight, and found eight men, nine women, and two young children in the house, which was a single apartment. The body of deceased was lying in the centre of the room. When Lieutenant Sloan passed the window of the house about two hours later there was still a noise as if the "wake" was being continued. The Fiscal explained that this was the first prosecution under the new Public Health Act in the burgh, although similar cases had been reported to the Sanitary Department.

For the defence it was contended that the men and women "held the wake" in the absence of Docherty, who only returned from Glasgow shortly before the second visit of the Sanitary Inspectors.

Bailie SMITH explained that the maximum penalty under the new Act was five guineas, but as this was the first prosecution he modified the fine to a guinea, with the alternative of a fortnight's imprisonment.

SALFORD SEWAGE EXPERIMENTS.

(*To the Editor of* THE SANITARY RECORD.)

SIR,—I note with very great pleasure your editorial remarks in THE SANITARY RECORD of March 4th with regard to my paper on "The Present Position of the Sewage Purification Problem," and I regret that the analyses which were given in my paper were omitted by the reporter, probably owing to the limitation placed upon him with regard to space.

In reply to your suggestions, I take the opportunity of sending you the following additional information with regard to the experiments in sewage purification carried on by the Salford Corporation under the direction of Mr. Joseph Corbett, Borough Engineer, together with the summary of such analyses as are at my disposal.

I may premise by saying that the River Conservancy Committee decided at an early date to carry on the experiment for their own information, and not as a national experiment carried on at the expense of the ratepayers of their own borough, hence the analyses have not been tabulated and published with the great care and voluminousness which have characterised the experiments carried on by the Massachusetts State Board of Health; and I am therefore prohibited from sending you details of the weekly analyses which have been taken for a long period of years.

The filtration of sewage on bacterial lines was commenced by Salford in February, 1893, or, in other words, soon after the publication of the Massachusetts Report, and Mr. Corbett, in advising his Committee to experiment on these filters, took up the work at the point at which that report left off. He believed that a very great deal of ventilation was essential to successful artificial filtration.

His first set of filters were, therefore, constructed in three heights, with a ventilation floor between each 20in. of filtering material, as described in THE SANITARY RECORD of February 25th, page 199, column 1.

The result of fifteen months' working, taking the average of a large number of analyses in parts per 100,000, was as follows :—

Solids in solution	88·00
Solids in suspension	0·
Free ammonia	1·29
Albuminoid ammonia	0·13

And this is considered to be a very successful result.

The tank effluent was applied at the rate of 1000 gallons per square yard for twenty-four hours alternate days, thus averaging 500 gallons per yard per day.

In July, 1895, the two filters 8ft. deep were constructed—page 199, column 2. Filter "E" had an area of $11\frac{2}{9}$ super yards, and contained four beds of small cinders from $\frac{1}{8}$in. to $\frac{7}{16}$in. in diameter, and 20in. thick, with three intermediate ventilated floors with spaces $4\frac{1}{2}$in. each, a total depth of 8ft.; filter "F" was the same area, and contained cinders of the same size, but in one mass 8ft. deep.

Each filter-bed rested on an open floor, with free outlet for air and water.

The analyses at my disposal date from May 2nd to October 10th, 1896, showing an average of about seventy-two hours' work per week, except when stopped for alterations to pipes, &c., at the rate of 500 gallons per square yard per day of 12 hours:—

	"E"	"F"	
Oxygen required in 4 hours	·843 ...	·768	per 100,000.
Free ammonia	·67 ...	·577	,,
Albuminoid ammonia ...	·188 ...	·165	,,

In the autumn of 1896 the Committee decided to test these filters to their utmost capacity, or to the point of destruction, and from October 12th for about twelve months, the filters were run practically continuously, the only stoppages being owing to the oiling and repair of machinery, and the average number of hours of work being over 160 per week. The analyses at my disposal date from October 12th, 1896, to April 1st, 1897, and the average of these is as follows :—

	"E"	"F"	
Oxygen required in 4 hrs.	·943	·837	per 100,000
Free ammonia...	1·15	·94	ditto.
Aluminoid ammonia ...	·184	·175	ditto.

Since the conclusion of that experiment, the filters were run for a short time at 500 gallons per square yard, and since then at 700 gallons per square yard.

It should be noted that while these filtration experiments have been in progress a large number of precipitation processes have been tried simul-

taneously, and the majority of these were, of course, unsuccessful, yet the effluents passed into these filters and were dealt with satisfactorily. I have no available figures as to the percentage of purification; Mr. Corbett has no doubt whatever but that the percentage of purification will be very high; but it will, of course, be seen that with an exceedingly bad tank effluent, highly charged with chemicals, the action of the bacterial filters will be considerably handicapped, and the analysis of the filtrate correspondingly unsatisfactory; these are included in the above averages.

The averages of monthly filtration tests between 1885 and 1887 are as follows :—

Free ammonia	0·483	in parts per 100,000.
Albuminoid ammonia ...	0·137	ditto
Oxygen absorbed in 4 hrs.	0·625	ditto

As a corroboration of these analyses I include an extract from the report dated 18th March, 1898, by the Rivers Committee of the Manchester Corporation.

The Manchester Committee visited the Salford sewage works on the 13th January, and took samples of the sewage, the tank effluent and filtrate, and the following is the report of their chemist :—

Salford Sewage Works,
January 13th, 1898.

DESCRIPTION OF SAMPLES.

Salford sewage, 4.5 p.m.—Blackish-grey, turbid liquid, with blackish-grey deposit

Pendleton sewage, 4.5 p.m.—Purplish turbid liquid, brownish-purple deposit.

Tank effluent, 4.5 p.m.—Liquid has brownish-purple colour, slight brown suspended matter; smells of some chemical refuse; is strongly alkaline.

Roughing filter, 4.15 p.m.—Slightly coloured and slight turbidity.

Final filter, 4.20 p.m.—Bright, clear, and colourless, no smell.

Analytical Numbers.

	Grains per gallon. Oxygen absorbed four hours.	Free and Saline Ammonia.	Albuminoid Ammonia.	Chlorine.
Salford sewage (shaken)	5·28	2·00	·50	—
(settled)	3·88	1·80	·34	10·4
Pendleton ,, (shaken)	7·58	1·40	·75	—
(settled)	5·86	1·60	·34	17·2
Tank effluent...	3·16	1·20	·23	17·0
Roughing filter	2·58	1·10	·22	16·2
Final filter	·60	·48	·06	—

Incuba'or Tests.—Three minutes' Oxygen absorption.

	Grains per gallon. before Incubator.	after Incubator.	Putrescibility.
Salford sewage...	1·44	1·92	Putrid in 5 days.
Pendleton ,, ...	1·54	2·00	Putrid in 5 days.
Tank effluent ...	1·12	1·05	Very slight smell after 5 days.
Roughing filter...	·86	·74	Very slight smell after 5 days.
Final filter	Not determined, as quantity insufficient.		Quite sweet.

In reply to your criticism as to the amount of sewage treated as exceeding in a very unaccountable measure that done by any other biological filters, of which you are aware; it was recognised as long ago as the first report of the Commissioners appointed in 1868 to inquire into the best means of preventing the pollution of rivers (Mersey and Ribble Basins), Vol. 1, 1870, page 64, that the quantity per cubic yard is the index of capacity of filters, and not the quantity per square yard, and on considering the figures given it will be found that they are not so very abnormal :—

	Gallons.			Gallons.	
Mr. Dibdin's filters	206½	at 3′ 6″	deep =	177	per c. yd.
Salford filters... ...	500	,, 8′ 0″	,, =	187½	,,
,, ...	1000	,, 8′ 0″	,, =	375	,,
,, ...	700	,, 8′ 0″	,, =	262½	,,
London Water Co's as quoted by you	540	per sq. yd.	=	?	,,

The special point of Mr. Corbett's filters is that the filters, like the Massachusetts, are throughout their whole depth open to the free and uninterrupted passage of sewage and fresh air; in contradistinction to the system introduced by Mr. Dibdin, where the filter is water-logged (especially the lower layers) for hours at a time.

So satisfied is the Salford Corporation with the efficiency of bacterial filters, that they have decided to lay down a sufficient area of these filters to deal with the whole of the Salford sewage at the rate of 500 gallons per square yard, on a filter 5ft. deep, or at the rate of 278 gallons per cubic yard of filtration material; and although the Local Government Board have refused to sanction the scheme unless the Corporation included a sum to cover the purchase of land over which the filter effluent might be turned and further purified, they have arranged to borrow £80,000 under Sec. 235 of the Public Health Act, 1875, and to construct the works without the necessity for obtaining the sanction of the Local Government Board.

It is interesting to remark that since my paper was read (I cannot claim it as a consequence of my paper) the Local Government Board has shown itself on the verge of being aroused from its state of "agnostical immobility," and has announced in Parliament that they have decided to appoint a Commission to examine the claims of efficiency on the part of bacterial filters.—Yours faithfully,

H. Gilbert Whyatt,
Assoc. M. Inst. C.E., M. San. I.,
Deputy Borough Engineer.
Town Hall, Salford, March 30th, 1898.

SEWAGE DISPOSAL AND WHEAT GROWING.

Sir,—The following account of an experiment in wheat growing is given by Mr. Brown, Smithy Farm, Congleton, as a result of using the product of the natural method of sewage disposal now firmly established at Congleton.

Mr. Brown carried out the experiment for his own satisfaction, having used the same product for years very successfully on other crops. The wheat experiment was on two acres, the produce of which was kept separate. The wheat from 9½ acres was thrashed on the 4th inst., and I here give the farmer's own words as to the results :—

"The 7½ acres of wheat grown in the ordinary way of manuring and rotation course yielded 8¼ bags of 12 scores per acre. The two acres which had been dressed with the Congleton manure (no

other manure used) yielded 12½ bags of 12 scores per acre, so that the absolute difference is 4½ bags per acre—over 50 per cent. more. There is no doubt in my mind that the excretions contained in the peat manure is the food *par excellence* for wheat."

I may here explain that the 17 bushels of wheat "extra yield" was produced at a cost of 15s. for manure, or less than 1s. per bushel; and that the expense in sowing, reaping, and threshing, was practically the same as for the poorer crop. When we consider that London destroys annually what would produce fifty million bushels of wheat, which London could restore to the farmer at a cost of 1s. per bushel for the wheat produced, we are forced to the conclusion that no sin could have been greater against nature. The farmer cannot help himself in this matter. He is practically asked to produce calico without cotton. His whole duty is to feed the teeming populations of our great cities, and he naturally looks to the cities for his necessary raw material in return. They offer him, not bread for his co-workers in nature (the bacteria of the soil) but stones. What, then, would be the consequence if the vast stores of raw material (the base things of the world which are despised) which the insatiable maw of the ocean now swallows were made accessible to the British farmer? Who can limit the increase of national wealth, national employment, and national home-grown food which would accrue to our country, if a true natural method of sewage disposal were established in place of the many tinkering artificial devices by which man's 'prentice hand has tried in vain to improve on nature, both as regards "artificial" manures and 'artificial" methods of sewage disposal?—Yours faithfully,

WILLIAM BOWLER.

Longsight, March 31st.

Notes and Queries.

Subscribers have the privilege of obtaining advice in this column on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed to THE EDITOR, "Notes and Queries," THE SANITARY RECORD, 5, Fetter-lane, London, E.C.

NOTE.—If an answer be required immediately, a stamped addressed envelope must be enclosed, when we will endeavour to furnish a copy of the answer by post, as owing to the large number of queries received we cannot guarantee the insertion of a reply in the succeeding issue.

1024.—SLAUGHTER-HOUSES: LICENSING AND REGISTERING OF.—"Subscriber" writes:—"With regard to the Powers of an Urban Sanitary Authority to license slaughter-houses, will you please advise (1) whether a slaughter-house in use before the passing of the Public Health Act, 1875, is held to be a registered slaughter-house? (2) If not, in what year were Urban Authorities first empowered to license slaughter-houses? The Towns Improvement Clauses Act, 1847, Section 126, refers to a special Act, the section reading that no slaughter-house shall be used (unless licensed) unless it was in use and occupation before the passing of the Special Act. Which is the Special Act referred to in this section?"

Answer.—(1) Slaughter-houses in use and occupation at the time of the passing of the Public Health Act, 1875, and so continued ever since, are required to be registered only as distinguished from licensed. (2) The Special Act has now to be read as the Public Health Act, 1875. In districts where the Public Health Acts Amendment Act, 1890, has been adopted, the provisions of Secs. 29—31 should not be overlooked.

1025.—DRAWINGS ON TRACING CLOTH: HOW TO MAKE.—"Amateur" writes:—"In making drawings on tracing cloth, I find that the ink does not flow freely, and suppose there must be something to mix with the ink or put on the paper. Will you please advise me what can be done?"

Answer.—Tracing cloth may be obtained glazed on both sides or on one side only. If the latter be used the tracing should be made on the unglazed side, and the colouring done on the glazed side. Where, however, the glazed side is to be used for the tracing, the difficulty of getting the ink to flow freely may be overcome by rubbing dry powdered whiting over the surface with a piece of rag. The whiting must, however, be all dusted off the surface before using the ink, or any whiting not removed will clog the pen. Another method adopted by draughtsmen is to use a little prepared ox gall (obtainable from any chemist), which is rubbed up with the ink, although when the ink is good and freshly made this is not generally necessary. For colouring the back of the tracing a little ox gall rubbed up with the colour will cause it to flow freely and evenly over the surface. Higgins' prepared liquid Indian ink, and Higgins' coloured inks, price 1s. per bottle, we may incidentally mention, will be found much more convenient than ink obtainable from cakes. These may be obtained from Messrs. J. Halden and Co., 8, Great Chapel-street, Westminster, S.W., and 8, Albert-square, Manchester, the well-known manufacturers of surveying instruments and apparatus.

1026.—HOUSES WITHOUT SUFFICIENT WATER-CLOSETS; DEFECTIVE DRAINAGE: PROCEDURE.—"F. J. A." writes:—"In this district we have a gentleman who is the owner of thirty-six houses in one street. The houses are divided into four blocks—of eight, five, eleven, and twelve houses respectively. My committee (after hearing the reports of the Medical Officer of Health) have instructed me to serve a notice or notices on the owner to put the property into a proper sanitary condition, and to pull down the present defective and insufficient privy and ashpit accommodation and substitute therefor the water carriage system. (1) Can the whole of the property be dealt with under one notice, or must I serve four notices, dealing with each block separately, or would it be necessary to serve a notice for each house? At present one privy serves for two houses, and there are sufficient privies in point of number, but they are not sufficient in a sanitary sense, as both privies and ashpits are built with 4½in. brick walls, liquid soaks through them, and they are generally in a very unsatisfactory state. (2) Have my Authority the power to insist upon water-closets (either slop or cistern-flushed) being provided in place of the privies and ashpits above described? I am aware we cannot specify which kind of water-closet shall be provided, this being at the discretion of the owner. (3) Can the whole of the insanitary arrangements of the property be dealt with upon one notice, or is it necessary to serve one dealing with privies and ashpits, another with asphalting the yards, another with the drainage?"

Answer.—(1) We should advise that a statutory notice be served in respect to each house. (2) Providing the Local Authority have not adopted a general rule requiring that water-closets shall be substituted for privies, and have inquired into the particular circumstances of each case and the particular requirements of each house, they may, if satisfied of the insufficiency of the privy accommodation from a sanitary point of view, require the provision of water-closets under Sec. 36 of the Public Health Act, 1875. In Wood *v.* Mayor, &c., of Widnes, 61 J.P., 647, it was held that a Local Authority have no power under Sec. 36 of the Act of 1875 to enforce as a general rule throughout their whole district or any part of their district the substitution of water-closets on a particular system. They must exercise their discretion upon the report of their surveyor or inspector of nuisances in

each particular case, and can only require the provision of a sufficient water-closet, &c., as the case may require, sufficient, that is, in a sanitary sense, having regard to the requirements of the particular case. (3) If the Local Authority elect to proceed under Sec. 94 of the Act in respect to the defective sanitary condition of the houses generally, they may do so, when one notice in respect to each house for defective (*a*) privy accommodation, (*b*) drainage and (*c*) yard paving, would be sufficient. Otherwise notices must be served separately if proceedings are intended to be taken under Sec. 23 for defective drainage, Sec. 36 for insufficient water-closet accommodation, and under Sec. 94 for defective yard paving. If the Public Health Acts Amendment Act, 1890, has been adopted the Local Authority may by bye-laws enforce the paving of yards to old as well as to new houses.

1027.—SURVEYORS' AND SANITARY INSPECTORS' APPOINTMENTS, &C.—"G. E. L." writes:—"I am desirous of gaining a post as Sanitary Inspector and Surveyor combined, and shall be grateful if you will answer me the following questions:—(1) What examinations have to be passed in order to qualify for these posts? (2) What are the best means of acquiring the necessary knowledge for these examinations? (3) How long will it take to complete the studies? (4) What is the average salary for the combined post of Sanitary Inspector and Surveyor? (5) Is there a good opening in the profession for energetic men? (6) Are there any limits as to age, &c.?

Answer.—(1) Unless a person has been trained in a Surveyor's office, and has had practical experience of the work and duties of a Surveyor to a Local Authority, he would find it almost impossible to secure a post as Surveyor to an Urban or Rural Sanitary Authority. He might, however, qualify himself for the examination of the Sanitary Institute for the certificate of an Inspector of Nuisances. (2) Probably the best way of obtaining the necessary knowledge for the Inspector's examination would be by taking a course of study under any one of the gentlemen who "coach" for these examinations, advertisements as to which will be found in THE SANITARY RECORD. (3) This will depend greatly upon the student himself, but may be taken as between four and twelve months. (4) Probably £120 for the combined office, but we have no means of ascertaining definitely. (5) Whenever a vacancy occurs there is always a large number of applicants for the post. (6) A person cannot be appointed to such a post if he is under twenty-one years of age, and generally advertisements for Inspectors prescribe that candidates must not be over forty years of age.

1028.—SANITARY INSTITUTE EXAMINATIONS: QUALIFICATIONS.—"Student" writes:—"Having gone through a course of studies with a practical Sanitary Engineer, I am doubtful as to whether I should present myself for examination at the London May Examination of the Sanitary Institute. My biggest drawback is that I cannot sketch; but setting that aside, I think I could probably get through. I have been working very hard for six months. Would you advise me to postpone presenting myself until December?"

Answer.—We can scarcely, we think, be expected to decide on the chances of candidates passing examinations, as we have no means of knowing their qualifications or knowledge, and such questions should be addressed to the professional "coach" who prepares pupils for examinations. Moreover, the information is not of general interest to our readers. If the candidate, in this instance, has procured "Model Answers to the Examination Questions for Sanitary Inspectors," price 2s., published by the Sanitary Publishing Company, and which should be in the hands of all candidates, and he is enabled to answer the questions in a manner closely approaching the answers therein given, notwithstanding his inability to sketch accurately, which is no doubt a serious defect, he may nevertheless be advised to sit at the forthcoming examination in May. If he fails at this examination, he may then present himself at the December examination on payment of half fees on giving the usual notice.

1029.—HOUSING OF THE WORKING CLASSES ACT, 1890: PROCEDURE FOR CLOSING HOUSES.—"M.O.H." writes:—"Kindly inform me if it is necessary to describe the work required to be done when a notice under Form A, Schedule IV., of the above Act, is served upon the owner of a house unfit for human habitation. Can you give me a case where the point has been raised? If so, where can I get the report of it?"

Answer.—In proceedings under Sec. 32, Sub-section 2, of the Housing of the Working Classes Act, 1890, which may be taken for the express purpose of causing the dwelling-house to be closed, the form of notice prescribed (Form A, Schedule IV.), does not specify any work required to be done, and it appears to be impossible to contend that it should do so. If proceedings, however, be taken under Sec. 32, Sub-section 1, of the Act, the first step in the procedure is to give notice to the owner to carry out such works as may be necessary to put the house in proper condition, and on his failure to do so to apply to justices for a closing order. The form of notice under Sec. 32, Sub-section 1, will be similar to that under Sec. 94 of the Public Health Act, 1875. Our correspondent will find in the notes under Sec. 94, in Lumley's "Public Health," a number of cases bearing on the point raised by him. If, however, he is advising his Authority to take proceedings for the express purpose of closing the house, these should be taken under Sec. 32 (2) of the Housing of the Working Classes Act, 1890.

1030.—CONSERVATORY: PLANS OF: REQUIRED UNDER BYE-LAWS.—"E. G." writes: "Could you tell me whether it is compulsory to submit plan of conservatory to a Local Authority? The building is to be heated by hot water, and will be built adjacent to a detached house, but with no direct communication with the interior of the house. I have been given to understand that such buildings are exempt so far as submitting plans to Council are concerned."

Answer.—The building referred to will not be exempt from the operation of the Building Bye-laws, and plans should be submitted to the Local Authority. The exemption only extends to "buildings erected and used, or intended to be erected and used, exclusively for the purposes of a plant-house, orchard-house, summer-house, poultry-house, or aviary, *which shall be wholly detached, and at a distance of 10ft. at the least from any other building*, and which shall not be heated otherwise than by hot water, and in which the fireplaces (if any) shall be detached, with no flues of any kind within such plant-house, orchard-house, summer-house, poultry-house or aviary." The building proposed to be erected does not comply with the requirements of this clause, and is therefore, as we have said, not exempt.

1031.—BUILDING LINE: AUTHORITY CANNOT PRESCRIBE FOR BACK WALLS OF HOUSES.—"R. W. G." writes:—"Am I correct in saying that an Urban Council have power to make the architect of a proposed new building set back the walls of the building at the back of the house, so as to keep them in line with the adjoining buildings? The architect wishes to bring out the new building 4ft. beyond the line of existing adjoining building, and thinks he has power to do so. Please give me your opinion. I enclose page of bye-laws *re* air space, and should thank you for your expression of opinion."

Answer.—Neither an Urban nor a Rural Sanitary Authority have any power to enforce a building line for the back walls of houses when these abut on yard spaces. The Building Bye-laws do not apply to such cases except so far as to prescribe the amount of open space which must be provided, and the minimum distance of space to

be allowed between the rearmost wall of the domestic building and the boundary of the premises. Sec. 3 of Public Health (Buildings in Streets) Act, 1888, applies and prescribes that "it shall not be lawful in any urban district, without the written consent of the Urban Authority, to erect and bring forward any house or building in any street or any part of such house or building beyond the front main wall of the house or building on either side thereof in the same street, nor to build any addition to any house or building beyond the front main wall of the house or building on either side of the same." It must be observed that the section is restricted to the *front* wall of buildings, and not to cases such as that mentioned by our correspondent. If the plan complies with the requirements as to open space at rear, and is not otherwise in contravention of any bye-law, the Urban Authority will not be enabled to refuse approval of the same.

1032.—LEGAL PROCEEDINGS: NOTICES BY SURVEYOR OR SANITARY INSPECTOR INSUFFICIENT.—"X. Y. Z." writes:—"In a county borough can any of the following officials prosecute before they have laid their case before their Committee or Council, and received their instructions to do so, viz.:—(1) The Surveyor to the Authority, when a person erects a building contrary to the building bye-laws; (2) an Inspector of Nuisances, when a person refuses to comply with an order for the abatement of a nuisance; (3) an Inspector under the Food and Drugs Act, when he discovers a contravention of that Act has been committed? If they can do so, under what Acts, or sections of same, have they the power? If not, have any cases been decided in any courts against them? Further, can a Council, by special resolution, give them the power, and, if so, under what Act and section?"

Answer.—(1) and (2) In neither case can legal proceedings be instituted, except and until the complaint has been laid before the Local Authority, and they have determined to prosecute. Under the Building Bye-laws it is the Council who are to institute proceedings, and under Sec. 94 of the Public Health Act, 1875, it is the Local Authority who must issue the notice. Neither the Surveyor nor the Inspector is the Council or Local Authority, and any legal proceedings instituted by them, without the complaint having been first reported to the Local Authority would fail. (See Vestry of St. Leonard's, Shoreditch, *v.* Holmes, 50 J. P., 132.) (3) An Inspector under the Food and Drugs Act, appointed by a County Council, will, we are of opinion, be enabled to prosecute for offences under the Act without the direction of the body appointing him.

1033.—OLD HIGHWAY BECOMING NEW STREET UNDER BYE-LAWS.—"Gus" writes:—"I send you tracing," (not reproduced) "showing plans of buildings proposed to be erected on land adjacent to a public highway, which latter is only 26ft. 9in. in width at this point. Immediately beyond this point the road is a private street, laid out the full width according to the bye-laws. I shall be glad to be informed whether the Council have the power to compel the owner to set back his building line 18ft. from the centre of the existing highway, and if so, whether under the circumstances you could take the centre as being midway between the forecourt wall and the fence on the opposite side of the road, or from the outer edge of kerb to the opposite fence. My Council have not yet adopted new bye-laws as an Urban Council,

INSURANCE.

THE MUTUAL LIFE INSURANCE COMPANY OF NEW YORK.

but are working under the bye-laws of the Rural Authority of which they formerly formed a part. A copy of the bye-laws is enclosed."

Answer.—The question as to when an old highway becomes a new street, to which the Bye-laws as to width of Streets apply, is always a question of fact. An ancient highway, it has been decided over and over again, may become a new street within the meaning of Sec. 157 of the Public Health Act, 1875, and the bye-laws made thereunder. (See Robinson *v.* Barton Local Board, 21 Ch. D., 632, &c.) In the case named by our correspondent, the bye-laws of the Rural Sanitary Authority are exercisable under Sec. 275 of the Act of 1875 by the present Urban Sanitary Authority. These bye-laws prescribe that new streets must be of a width of 36ft. Taking into consideration the circumstances of the case, we are of opinion that the Local Authority will be enabled to require the forecourt wall to the proposed new houses to be set back a distance of 18ft. from the centre of the old highway.

Vacancies.

BUILDING INSPECTOR (LITHERLAND, LANCS, April 16th).—For the Urban District Council. Salary £110 per annum. Messrs. North, Kirk, and Cornett, clerks to the Council, 15, Lord-street, Liverpool.

ELECTRICAL ENGINEER (DEWSBURY, April 9th).—For the Corporation. Salary £250 per annum. Mr. G. Trevelyan Lee, town clerk, Town Hall, Dewsbury.

SURVEYOR, &C. (SWADLINCOTE, April 11th).—For the Swadlincote District Urban District Council. Salary £200 per annum. Mr. W. A. Musson, clerk, Market-street, Ashby-de-la-Zouch.

Contracts Open.

The dates given below are the latest up to which tenders can be received.

POKESDOWN (NEAR BOURNEMOUTH).—April 9th.—Sewers, &c.—Mr. Edward Wembridge Ingamells, engineer and surveyor, Council Offices, Pokesdown, Bournemouth.

CHURCH (LANCS).—April 11th.—Sewering.—The Surveyor, Urban District Council Office, Church.

DUKINFIELD. — April 12th.— Sewage Purification Works.—Messrs. Newton, 17, Cooper-street, Manchester.

WEDNESFIELD.—April 14th.—Sewerage Works.—Mr. R. E. W. Berrington, 1, 2, and 3, Bank-buildings, Lichfield-street, Wolverhampton.

ULVERSTON.—April 13th.—Sewerage Works.—Mr. Joseph Greenwood, Union Offices, Ulverston.

WASHINGTON (DURHAM).—April 13th.—Sewers.—Mr. George Lymon, surveyor, Birtley.

METHLEY (YORKS). — April 18th. — Sewers.—John Richardson, Esq., J.P., Methley Park, Leeds.

COMPETITIONS.

CRICKLADE (WILTS), April 30th.—Water Supply Plans.—The Cricklade and Wootton Bassett Rural District Council invite engineers to forward a report, with plans and estimates, for furnishing an effective system of water supply to the town of Cricklade, Wilts, exclusive of the cost of the land or easements, but inclusive of all other expenses. Premiums of £21 and £10 10s. will be given for the plans which the Council shall adjudge to be first and second in order of merit. Mr. Harry Bevir, clerk, Union Offices, Wootton Bassett.

FORMBY (LANCS), July 1st.—Sewerage Scheme.—The Formby Parochial Committee invite competitive schemes for the sewerage of a portion of the township of Formby. Premiums are offered amounting to £100 for the scheme considered first in order of merit, £50 for the second, and £25 for the third. Mr. J. H. Havelock Sutton, Piercefield-road, Formby. A professional assessor will be appointed to adjudicate upon the plans.

DR. ERNEST HART.—The will, which is dated January 3rd, 1898, of Dr. Ernest Abraham Hart, of Fairlawn, Totteridge, M.R.C.S., editor of the *British Medical Journal*, who died on January 7th last, aged sixty-two years, has been proved by his widow, Mrs. Alice Marion Hart (daughter of Mr. Alexander Rowland), Mr. Stephen Simon Hyam, of Finsbury-pavement, solicitor, and Sir Ernest Clarke, of 13, Hanover-square. The testator's personal estate has been valued at £15,966 6s. 11d. gross and £12,114 18s. 11d. net.

WORSHIPFUL COMPANY OF PLUMBERS.—At a public meeting held at the Town Hall, Durham, the following resolution was carried unanimously:—"That this annual general meeting of the North of England District Council for the National Registration of Plumbers is of opinion that an organised and efficient system of registration of qualified plumbers is essential to the protection and preservation of the health of the community, and records its approval of legislative sanction being given to the registration movement, and its desire that the members of Parliament in the district will support the Bill now before the House of Commons."

To Surveyors, Sanitary Inspectors, &c.—First-class Cycles at reasonable prices. Don't place your orders elsewhere until you have seen our post-free catalogue.—MELROSE CYCLE COMPANY, Coventry.

SCHERING'S NEW DIETETIC.

This is a new albumen preparation for domestic use. Its constituents, similar to milk, especially Human Milk, give it a peculiar value.

SANOSE

SANOSE is an odourless and tasteless white powder, forming an emulsion when stirred in water.
THE MEDICAL PROFESSION strongly recommends it in cases of Anæmia, Dyspeptic troubles, Consumption, and in Cachectic Women.

For literature see "THE THERAPIST," November, 1897, and January, 1898.

Price 1s. per ounce; 3s. 6d. per 4 ounces.

DR. TIBBLES' VI-COCOA.

ARTICLE No. 3.

ITS STRENGTH-GIVING PROPERTIES.

DR. TIBBLES' Vi-Cocoa is a skilful combination of Kola nuts, malt, and hops, with the purest Caracas cocoa. That ordinary cocoa is somewhat lacking in stimulant properties as compared with tea and coffee is a proposition that will be readily conceded by all who can take either without any discomfort.

But there are many who cannot take tea without suffering from indigestion, nervousness, a feeling of tremulousness, and other symptoms indicating irritation of the stomach. Others are equally uncomfortable if they take coffee, and fall back upon cocoa. Although the cocoa seed or nib has an aromatic flavour that by most people is considered agreeable, especially when flavoured by vanilla and sweetened as in chocolate, yet it is deficient in the stimulating and refreshing properties of tea and coffee. These properties are generally affirmed to be due to the active principle called caffeine which both tea and coffee possess, but which is not present in cocoa.

The unpleasant effects produced in some constitutions by tea and coffee are believed to be due to small quantities of volatile ingredients contained in them. But there is a seed which is largely used in Central and Northern Africa, and which contains the same active principle as tea and coffee, but without any injurious ingredient whatever. This is the Kola nut. It is nearly allied to cocoa, since it belongs to the same natural order of plants, and contains also the same active principle as cocoa, viz., theobromine. It has, however, not the agreeable flavour of cocoa but a rather insipid taste.

By mixing this perfectly harmless seed with cocoa in definite proportions, it imparts to it the advantages of the caffeine, without communicating any flavour of its own, and thus confers on the cocoa the stimulating properties of tea and coffee without their disadvantages.

As attempts have been made by ignorant persons to depreciate, apparently for business purposes of their own, the value of Kola, reference is made here to a few of the large number of published statements by competent authorities on the subject.

Dr. Daniel, who lived for some time at Sierra Leone, states in the *Pharmaceutical Journal* (1865 (2), vol. xi., p. 450—456) :—"It would be difficult to find any product which occupies such an exalted position in the social and dietetic economy of the Negro tribes, and which constitutes such an important article of commerce in the Soudan as the Kola nut. . . . For many years these valuable commodities have been offered for sale in the markets of Fez, Tripoli, and other depôts on the shores of the Mediterranean. . . . One remarkable feature, worthy of attention, is the marked avidity displayed by the Negro inhabitants of Sierra Leone and the Portuguese colonies for the nuts in preference to the beverages of tea and coffee, although these contain the same alkaloid."

The high importance of Kola has been recognised by the Kew Authorities, by whom this statement is made :—(*Kew Bulletin*, November, 1890, p. 254)—"From 1880 onwards, the Kola plant has been propagated at Kew, and steadily distributed from there."

Sir Alfred Moloney, C.M.G., speaks very highly of the Kola nut in his "Forestry of West Africa," page 162, and remarks, "Attention to its development is indeed small compared with what may prove to be the importance any demand for the Kola in the future, whether as Kola chocolate, or in view of the steady spread of Mohammedanism from North-East Africa towards the West, to meet the proportionately increasing want by its followers, of a stimulant other than that resulting from the degrading and degenerating use, more frequently than not in excess, of imported spirit appropriately called the 'fire-water' of the white man."

Mr. Peter Boa records in the *Pharmaceutical Journal* (April 1892, page 842) a candid and evidently unbiassed opinion concerning Kola nuts as follows :—"My own experience of Kola is that as a beverage, say, for breakfast use, its effects last longer than the effects of tea and coffee similarly taken." He adds further, "Mr. Henry had some experience of the stimulating and sustaining effects of Kola during walking expeditions, and similar prolonged exercise. Its effects were similar to cocoa, but it possessed the advantage of warding off the pangs of hunger."

The evidences of the value of Kola are overwhelming, and only those ignorant of the literature of the subject would venture to make any statement to the contrary.

As a result of trade jealousy consequent upon the unprecedented success of our unique preparation, derogatory statements devoid of the slightest particle of truth are being widely circulated.

The Proprietors of Dr. Tibbles' Vi-Cocoa guarantee that each packet is not only harmless but is absolutely beneficial to the most delicate invalid or the youngest infant.

A little book containing the reports of the very highest medical experts and analysts in the United Kingdom, showing the advantages of Dr. Tibbles' Vi-Cocoa over all other food products, will be forwarded post free on application (a post card will do) to any medical man, along with a large sample tin. Address : Dr. Tibbles' Vi-Cocoa, Ltd., 60, 61, and 62, Bunhill Row, London, E.C.

SITUATIONS.

VACANT.

THE

Sanitary Record,

APRIL 15, 1898.

POWERS OF LOCAL AUTHORITIES IN REGARD TO WATER-CLOSET ACCOMMODATION.

THERE have been two cases recently decided in the Courts on this subject, which should serve as useful guidance to Local Authorities in the exercise of their powers in enforcing the provision of sufficient water-closet accommodation; or, more properly, in enforcing the substitution of water-closets for privies, under Sec. 36 of the Public Health Act, 1875.

The first case to which we refer is Wood *v.* Mayor, &c., of Widnes, in the Queen's Bench Division, on July 24th last (61 J.P. 646), and which was carried to the Court of Appeal January 26th, 1898 (62 J.P. 84). In this case the Local Authority had passed a general resolution on the 12th February, 1895, which was to the effect that, "in all future cases of nuisances regarding the reconstruction of privies and ashpits, the Local Authority of this borough do, as far as practicable, order that such privies and ashpits be converted into the waste-water closet system, or into such other system as the Local Authority may from time to time approve, and that the Highway, &c., Committee be requested to take such steps for the adoption of the first-named system generally throughout the borough."

Subsequent to this resolution the officers of the Local Authority reported that a large number of houses in a particular district of the borough, and numbered in batches consecutively, were without sufficient water-closets. Notices were then given by the Local Authority to the owners, requiring water-closets to be provided on the waste-water closet system, in accordance with plans and specifications which it was stated by the notice could be seen at the office of the borough surveyor, such notices not being given in respect of each house, but in respect of whole batches of houses at a time, and not condescending, as Ridley, J., pointed out, to deal with the different requirements of different houses. He also observed, as did Lawrence, J., that a Local Authority are not entitled to say, "You shall have a water-closet of a particular pattern, or a particular size, or on any particular system." If the owner provides a sufficient water-closet, that is, a water-closet which is sufficient in a sanitary sense, that is all that the Local Authority have the right to call upon the owner to do. Here the Local Authority had made a general rule for the substitution of water-closets on a particular system in the place of privies, and that was against all the authorities. Lawrence, J., held that the resolution of the Council of the 12th February, 1895, was not valid, and that it invalidated all subsequent proceedings, and Ridley, J., held that the discretion of the Local Authority, under Section 36 of the Public Health Act, 1875, ought to be exercised in each case with regard to the circumstances of that particular case, and the owner or occupier ought to have the opportunity of choosing for himself the kind of w.c. he will have subject to the necessity that it should be a sufficient w.c. within the meaning of the Act of Parliament; sufficient, that is, in a particular sense, of which the Local Authority are to be the judges, having regard to the requirements of the particular sense. This case was carried by the Local Authority to the Court of Appeal (62 J.P. 84), but the appeal was dismissed, the Court holding that the Corporation had not considered the requirements of each individual house, but had acted in pursuance of a general scheme.

The second case to which we refer is that of Robinson *v.* Mayor, Aldermen, and Burgesses of Sunderland, and came on for trial before Ridley, J., at the Durham Assizes on March 4th (62 J.P. 216), and was an action brought by the owner claiming an injunction restraining the Corporation, their servants, &c., from entering upon his premises for the purpose of doing the works specified in a notice calling upon him to provide a sufficient water-closet to a certain house within the district of the borough.

This case differed from Wood *v.* Mayor, &c., of Widnes in that the Corporation had not passed

a general resolution to the effect that the water-closet system should be substituted for privies, &c. But the Corporation, however, had required by their notice that the owner should provide a sufficient water-closet to the house, according to a particular specification given by the notice. Ridley, J., held that the plaintiff was entitled to succeed on the ground that the Corporation required him to supply one particular kind of water-closet, when they ought simply to have required him to supply a sufficient one.

These cases, as we pointed out earlier, will serve as a guidance to Local Authorities in proceeding under the provisions of Sec. 36 of the Act of 1875; and we doubt not that Authorities henceforth will avoid proceeding (1) by way of a general resolution to enforce the substitution of water-closets for privies, and (2) by requiring a water-closet of any particular pattern or system to be provided. It will be advisable, we are of opinion, for those Authorities which have such a general resolution on their minutes to have the same rescinded before taking further proceedings thereunder, in order to avoid litigation, which it is evident can only have one result, and that is against the Local Authority.

Notes.

Food Adulteration.

It is abundantly manifest that opinion in the provision trade and the other interests concerned with regard to the proposed changes in the law relating to food adulteration is in a very unsettled state. Less than a month ago we had occasion to note Mr. Chaplin's reception of a strong deputation from the Federation of the Grocers' Associations of the United Kingdom. That deputation wished to urge on the President of the Local Government Board the desirability of amending and consolidating the Sale of Food and Drugs Acts of 1875 and 1879 and the Margarine Act of 1897, on the lines of the recommendations contained in the recent report of the Select Committee on the subject; but Mr. Chaplin was under the necessity of pointing out to them that the lack of unanimity of opinion, not only in parliamentary circles, but also within the ranks of the Federation itself, constituted a very serious difficulty in the way of the Government's legislative proposals. In particular, he instanced the divergence of views entertained by members of the Federation on the margarine question, many of them being strongly opposed to the recommendations of the Committee—that the colouring of margarine and the mixing of margarine and butter should be altogether prohibited.

A New Deputation.

And now we find another Deputation, also claiming to represent the provision trade and its allied interests all over the kingdom, waiting on Mr. Chaplin at the Local Government Board office, to urge on him the policy of non-interference with regard to the sale of margarine. Sir John Leng, M.P., who acted as principal spokesman of the Deputation, in introducing the subject pointed out that the shoal of petitions in favour of an alteration of the Food Products Bill that had lately been pouring into the House of Commons, all bore a common stamp. They clearly represented the agricultural interest. Now, it is no more than we should expect that this important question should be viewed differently by those engaged in agriculture and by the provision trade. The latter maintain that the law relating to the sale of margarine is ample, if properly enforced. But Mr. Chaplin, while promising to give all due weight to the views urged upon him, very properly reminded the deputation that, in considering what legislation was necessary, the chief consideration must be the interests of the community at large, and not those of any particular trade or industry.

The Need for an Authoritative Court of Reference.

We observe, in connection with this subject, that the *Daily Mail* has been giving prominence to the views of Dr. Bernard Dyer, not in relation to margarine simply, but on the whole question of the introduction of preservatives into food, and of food adulteration. The extent to which preservative substances are used is apparently quite unsuspected by the general public. Dr. Dyer points out that the evidence taken before the Select Committee has established that aniline dyes are now very largely employed in colouring foodstuffs, and that antiseptics are added to almost all perishable foods; and he further observes that in most continental countries the sale of food containing antiseptics is forbidden, the export of such food to this country, however, for our consumption, being freely permitted. The opinion of all the most eminent authorities, and especially of public analysts, is that the only way to deal with this question satisfactorily is to leave it to the determination of the Court of Reference to be constituted in accordance with the Select Committee's recommendations. It should be empowered to fix the food standards, and also to decide what preservatives, if any, should be used, and in what quantities—instead of leaving such matters to the varying decisions of individual magistrates, who have no other guide but the evidence that may happen to be laid before them.

Diseased Foreign Produce.

The drift of certain questions in the House of Commons by Sir Mark Stewart and others seems to point to a growing belief among British politicians that it is time that we checked the free importation of diseased foreign produce by more stringent supervision at the port of entry. Mr. T. W. Russell has admitted that at present dairy produce is imported in large quantities from countries that possess no such regulations as to dairies and cowsheds as we do. In fact, as we recently pointed out, the importation of such produce is steadily on the increase; and the only precautions that exist for the protection of the consumer are the same as in the case of home produce, viz., that Medical Officers of Health and Inspectors of Nuisances have power to examine any animal, carcase, milk, or other suspected articles deposited for sale, and to seize any which they consider unsound or unfit for human consumption. But many people now hold that the Government should adopt more rigorous precautions than these with regard to foreign pro-

duce, especially when we know that it comes from places where the most insanitary conditions prevail. For example, there is no proper system of inspection or analysis of foreign milk, and if it happens to be infected, once it is beyond the control of the Port Authorities, there is no saying what harm it may not do. The fact that we know and can control the conditions under which the home produce is supplied, and that we have no such knowledge or control with regard to foreign produce, justifies us in differentiating between them, and checking the latter at the port of entry.

Manchester and the Sewage Question.

Manchester, like many other towns, is now face to face with the difficulties of the sewage question. They have been studying the modes adopted in Sutton, Barking, Glasgow, Oldham, and elsewhere, for the treatment of sewage and the disposal of the effluent, and have decided to embark on a scheme which is to cost, it is estimated, about £170,000. Unfortunately—and in this respect their experience has been by no means singular—friction has arisen with the Local Government Board over the proposed loan, and in particular with regard to the Board's preliminary requirement that more land should be acquired for dealing with the sewage effluent by means of irrigation. On this question the Rivers Committee of the City Council are at direct issue with the Board. They believe that for them irrigation would be not only costly, but altogether futile; whereas the scheme they advocate is, they are convinced, as the result of inquiry and personal observation, the cheapest and most effectual means now known of dealing with sewage. In the event of no compromise being possible, the Council may be under the necessity of going to Parliament for the necessary powers; but there are some who deprecate any conflict with the Local Government Board, and are in favour of holding the matter over until the report of the Royal Commission has been issued, estimates being meantime taken of the cost of construction of the proposed filters. No better illustration could be had of the necessity of this Commission, and of an authoritative pronouncement being made as soon as possible on the whole question of sewage disposal. It looks, however, as if the Council of Manchester are not very much in earnest, for at their last meeting the discussion resulted in a count out!

County Council Instruction in Dairy Work.

We are indebted to the Essex County Council for a return showing the extent to which instruction in dairy work is carried on under the auspices of County Councils. From this it appears that twenty-six counties at present employ travelling instructors, some for the whole year, others only for the principal dairying months. We find also that sixteen Councils support "fixed schools." The term must not, however, be understood to mean absolutely permanent institutions. In point of fact, the school in some places may be "fixed" at one centre for so many months in each year, or different centres may be selected in successive years, so that the benefit may be distributed over the entire county. The return also gives details as to the respective cost of these schools, but being compiled on no common principle, they differ so widely that they are statistically comparatively useless. Information is also given as to the hours of work and the staff employed. The remuneration of head teachers varies from £80 to £120 per annum.

Economic Progress of Electricity.

Mr. Hammond's paper at the recent meeting of the Institution of Electrical Engineers gave us some most interesting figures illustrating the reduction which has taken place within late years in the cost of the generation and distribution of electrical energy. In Leeds, for example, the selling price, which was 8d. per unit four years ago, is now only 4d. As to the cost per unit sold, in 1894 the lowest result was obtained by Manchester, the cost being 2·17d. per unit. We now find no fewer than fifteen towns that can show a lower cost of production, some of the principal rates being as follows:—Edinburgh, 1·13d.; Manchester, 1·45d.; Portsmouth, 1·71d.; Leeds, 1·73d.; Liverpool, 1·77d.; Bradford, 1·81d.; Glasgow, 1·92d.; Brighton, 2·04d; and so on. There are now 121 works in existence, principally for lighting purposes. These figures betoken extremely satisfactory progress. Mr. Hammond's paper was also instructive as indicating the directions in which further decrease in cost might in the future be attained.

Scottish Building Regulations.

The Convention of Scottish Burghs, at their annual meeting last week, adopted some important resolutions, some of which are of general interest to sanitarians. And the first to which we should like to draw attention is one for the establishment of a code of building regulations for all burghs in Scotland having a population exceeding 10,000. Such a code was adopted in Glasgow in 1892, under a special Act of Parliament, and it has proved of the greatest service not only to the Dean of Guild Court, but also to architects and others engaged in the building trade. The Authorities are thereby empowered to secure the proper ventilation of all blocks of houses, erected in hollow squares, by means of ventilation lanes; and the resulting benefit to the sanitation of the city has been immense. The adoption of such building regulations in crowded centres of population will prevent the recurrence of those congested areas and ill-ventilated and insanitary dwellings which are the bane of our larger towns; and experience also teaches that they have a most marked influence on the prevention of fires due to defective construction.

Sanitary Dwellings for the Poor.

Another important resolution was one in favour of obtaining powers from Parliament entitling municipalities to erect sanitary dwellings for the poorer classes. The resolution was moved by Mr. Chisholm, of Glasgow, who drew a vivid picture of the kind of houses the very poor at present inhabit—houses

situated in narrow streets, lanes, or alleys, or in back lands; with high garrets, up ricketty stairs, and even down in cellars, or what might be called such; damp, unwholesome, free from light and air; in a word, destitute of the very elementals of sanitation. The difficulty, however, experienced by all large towns in dealing with this question of the slums, arises from the high price of land, which in many cases renders almost prohibitive the attempt to provide really good, though plain, houses for the labouring population at rents that are within their means. The private builder at least will not do it, but the task is not altogether beyond the power of municipalities, with their easy command of money at low rates. Mr. Chisholm said that in Glasgow they had provided one-room houses at rents of £4 10s., and two-room houses at rents of £7, and had besides not only paid the interest on the invested money, but had also been able to carry a considerable amount to the general depreciation fund. And if it had been proved possible to do this in Glasgow, why should not municipalities in general be invested with similar powers, without the necessity of going to Parliament in each individual case?

The Midwives' Registration Bill.

At the meeting of the General Medical Council last week, when Sir William Turner, of Edinburgh, was elected president, in room of the late Sir Richard Quain, the Midwives' Registration Bill formed the principal subject of discussion. After protracted deliberations, the Council approved of the Bill, subject to certain conditions, and if these are adopted the effect of the Bill will be this—that midwives should be licensed annually, instead of being registered permanently; that a central board for the supervision of midwives should be established, which is to lay down regulations for their education and the manner in which they may practise, which must be approved by the Medical Council; that each midwife should further be under the direct supervision of the local Sanitary Authority for the district in which she resides; and that every unlicensed person who practises for gain in future should be punished. It is understood that at present considerably more than half the confinements in England are conducted by midwives, instead of by members of the medical profession, and as the question affects the well-being of more than half a million of mothers in England and Wales annually, the measure is one of very far-reaching importance.

The Consumption of Condensed Milk.

The statistics that appeared in a recent article in the *Times* showing the increased importation of condensed milk into this country, are interesting and instructive. Taking the first eight weeks of 1896, 1897, and 1898, the following quantities were received:—1896, 109,855 cwt.; 1897, 116,792 cwt,; and 1898, 152,067 cwt.; showing an increase this year of 30 per cent. over last year, and of 40 per cent over 1896. It is not unreasonable to suppose that this increased consumption of condensed milk, which is almost entirely an article of foreign manufacture, is partly, perhaps chiefly, due to the conviction which is now entertained by many people of the danger of using unsterilised milk. So many epidemics have been traced to an infected dairy, so much alarming information has been circulated as to the prevalence of turberculosis, especially in city byres—there are said to be 800,000 tuberculous cows in the country—that it is small wonder that people are growing chary of the milkman's cart, which may be, for aught they know, the vehicle of scarlet fever, consumption, or who can say what nameless forms of dread disease.

The Benefits of Sterilisation.

It is no longer necessary, however, to resort to condensed milk in order to secure the benefits of sterilisation. Many dealers at home now supply milk which has been absolutely sterilised, and will keep sweet for an indefinite time by being sealed in air-tight bottles. The necessity for this latter precaution lies in the fact that sterilisation by boiling would of itself prove but a slender security against the development of germs, unless the air were to be also afterwards excluded; for it has been shown that some germs attain their greatest activity in milk which has been boiled and subsequently exposed to the air. Be this as it may, however, it is certain that the milk which can be had in air-tight bottles is not only absolutely safe, and free from the presence of germs, but it is also as sweet and palatable, and moreover nearly as cheap, as the best fresh milk. Were this more generally known, we feel sure that the use of sterilised milk would become more common, especially for the use of infants, and there would be a marked decline in the death-rate. Some medical authorities, indeed, go so far as to say that in large towns the rate of mortality would be reduced by 50 per cent.

A Zealous Lady Sanitary Student.

We have had brought under our notice an excellent example of the spirit of zeal on the part of a student in sanitary science, which we think deserves to be recorded for the inspiration of others. It is noteworthy, too, that the student in question is a lady—there is no need to mention names. She had been studying medicine—with a view, we presume, to practising as a doctor—and had all but finished her curriculum; but she considered that her medical course would not be complete without some practical experience in the field of sanitation, for which there was no provision at the University. She therefore applied for and obtained an appointment, without a salary, on the sanitary staff of the city in which she was studying—merely for the sake of gaining experience. Were such an example to be followed by most of our young doctors, who consider that they are well qualified in public health, if they go through a certain course of study and take a diploma, but without any experience of practical work, there would be a great advance in the knowledge of hygiene. University instruction is an excellent thing; but just as no medical education is complete without experience of hospital work, so no course of hygiene should be considered complete without a certain degree of experience in the sanitary department of a large town.

THE SANITATION OF DOMESTIC BUILDINGS.

By Frank Latham, C.E., M. San. Inst, &c., Assistant Surveyor, Borough of Margate.

CHAPTER VI.

Section 3.

SINKS.

Although slop sinks (which are places where servants empty their pails) are convenient in large establishments their adoption in ordinary buildings where proper pedestal closets are provided may be dispensed with, as it is important that the number of inside connections with the house drains should be minimised as much as possible, water-closet basins being now specially manufactured with a slop top, but with a good size basin this slop

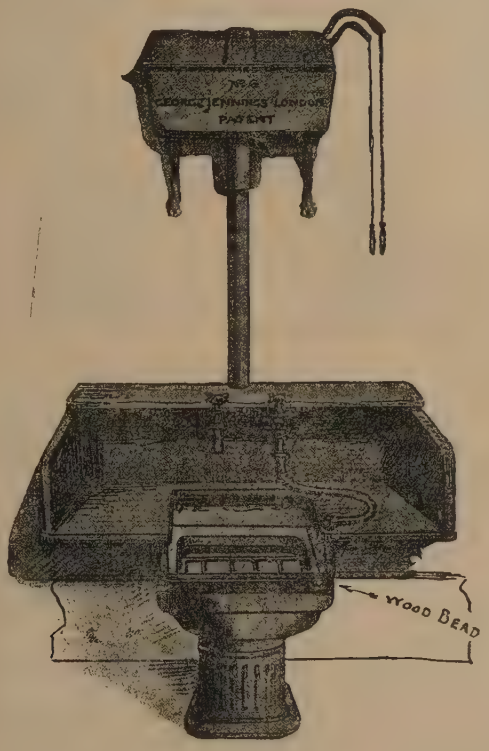

Fig 76.

sink is scarcely necessary. Slop sinks consist of an earthenware or porcelain enamelled iron basin, about the same size as that of a water-closet, and fixed in an open framing of woodwork, and connected with a special pipe by a 2½in. waste and trap similar in every way to the closet apparatus, the out-go pipe being well ventilated by means of a 2in. vent to prevent syphonage. In the top of the sink should be a slop top of the same ware also forming a flushing rim, and both sink and top manufactured in one piece (Fig. 76). A fillet of wood should be fixed in front of the sink to prevent pails coming into contact with the earthenware and breaking the apparatus. An enamelled iron grating is fixed at the bottom of the basin to prevent valuable or obstructive articles entering the drains. As in the case of closets, the inside surfaces should be washed by proper flushing apparatus, and a lead safe with waste pipe in 5lb. lead should be provided under the sink in case of spilling or overflow. It is very important that these sinks should be placed in good sanitary positions, no other situation but against an external wall with proper window to open being admissible. The method of placing them in unventilated chambers or on confined landings is specially objectionable.

Scullery and other sinks should be made impermeable, and of cleanly material adapted for the purpose intended. The waste pipe should be fixed in either the right or left-hand back corner, and the sink fixed to give a fall from all parts towards that angle so that it will drain itself. The commonly used white glazed earthenware sink with ordinary care answers as well as any, but it has its disadvantages when the household crockery, &c., comes in sharp contact with it. Wood is sometimes used as a protection for such utensils. Wood sinks lined with thick lead, or, better still, tinned copper, are recommended, and in some cases are to be preferred.

The white glazed earthenware sink is the best for washing vegetables and other articles of food in connection with the kitchen, the material being non-poisonous and easily kept clean.

Sink waste pipes should be of lead 2in. in diameter, and trapped directly under the sink by means of a syphon trap provided with brass

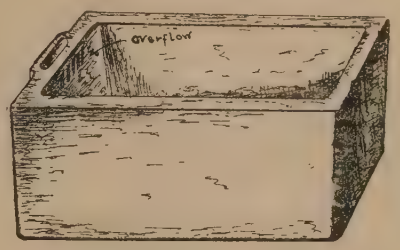

Fig. 77.

thumb-screw under, for cleansing purposes. The waste should be fixed by opening the inlet, and to ensure a fit with the outlet hole, the opened end being passed through the bottom, the pipe can be tafted over the inside of the sink, which is countersunk for that purpose. An ordinary brass grating can then, in the case of small sinks, be tafted over the waste. It is, however, necessary in the case of sinks required for washing-up purposes to adopt a brass cup grating, the cup being inserted in the opened end of the pipe in order that a plug may be used for retaining the water. In sinks of the latter description overflow pipes should either be provided in its manufacture, as in Fig. 77, or by means of a pipe connected with the waste on the house side of the trap.

Section 4.

URINALS.

The urinal is a most imperative necessity amongst sanitary fittings, and its extended use in hotels, schools, factories, and public conveniences has brought about great improvements in its construction. It is not an easy thing to contrive a sweet and cleanly urinal, and cheap ones are generally nasty. In all cases it is a matter of much consideration that the most sanitary form and service-

able value should be obtained. Urinals should be placed in well-lighted and ventilated positions, with due regard to convenience; if this rule is not kept in view, more or less, a nuisance is sure to result.

Urine is of a very corrosive nature, and will form a thick incrustation on the surfaces of an apparatus if at all neglected, even for a short period, which coating will throw off a strong and disgusting odour, besides sometimes corroding the small trap and

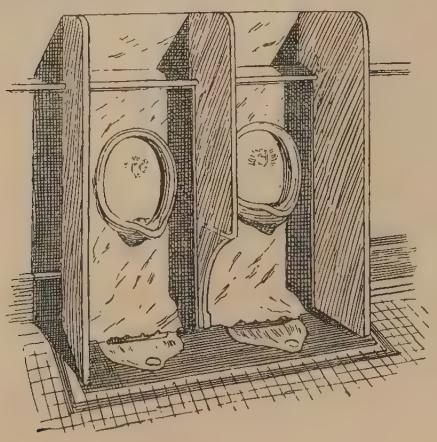

Fig. 78.

pipe found in some makes, and these being forced by some inexperienced person, will often become damaged, and the trap rendered useless, leading to the escape of drain air. Urinals, therefore, should be arranged so that they can be automatically flushed at frequent intervals with fresh water, the apparatus being also cleansed down at least once

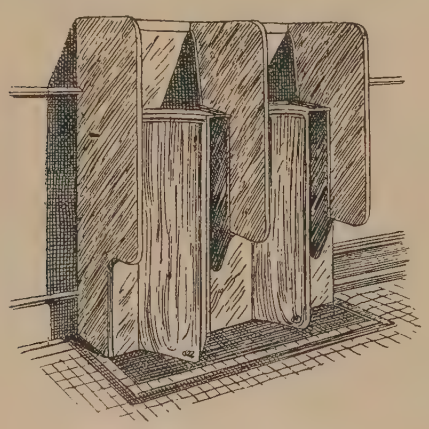

Fig. 79.

every day, and all corrosion removed. This will be found a comparatively easy matter if regularly done; when in a bad condition the use of hydrochloric acid may be necessary.

The best urinals should have no rough surfaces, unnecessary corners and joints, or any unprotected ironwork, to come in contact with urine. It is better to have no ironwork whatever, the flushing rims, &c., being either of copper or brass. The chamber floors should be tiled, cemented, or paved with impervious material, with falls towards the channels in connection with the apparatus, the urinals, together with floors and surroundings, being self-draining and easily cleansed.

There are several good patterns of urinals now in use, the most general form being an earthenware basin, containing fresh water fixed in a screened stall (Fig. 78). The water in the basin being more or less frequently changed by flushing from automatic syphon cistern or by treadle connected with a grating, which is stood upon by the person using the urinal, thus turning on the water for the time being.

In the case of the basin urinals with gratings, a proper impervious floor should be laid under the grating, with a channel leading to a gully trap, so that the whole can be properly flushed.

Some of the best forms of urinals now produced consist of stalls with cream or salt glazed ware semi-circular radials or bays, having floors of the same material, with falls towards a trap in front. The floor surrounding the urinal is laid with falls towards the same gully, so that every part can be sluiced down with fresh water, and the contents carried away down the drains (Fig. 79). These

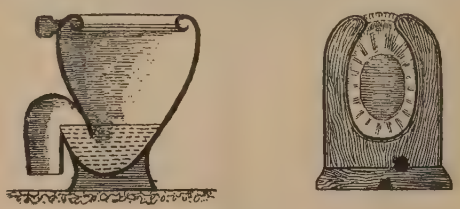

Fig. 80.

urinals are very simple and strong in construction, and should have no joints or angles to collect filth, so that they can be kept effectually clean with a small amount of attention; the floors and backs should be manufactured in one piece, thus doing away with a joint between the two. A disinfecting block, suspended in the flushing cistern, has a beneficial effect. Hope's Pynerzone blocks and suspenders for this purpose give off a pleasant odour, and maintain the lavatory compartment sweet and fresh. Urinal waste pipes should be trapped immediately after leaving the apparatus, and amply ventilated by a proper ventilation pipe and anti-syphonage before entering the drain.

A new and welcome departure in sanitary apparatus is the "Urinette" (Fig. 80). This contrivance is on the principle of a water-closet, but considerably smaller, thus requiring but little floor space; the object being its adoption in factories and such places where women are employed, and answers somewhat the same purpose as the urinal in the men's section. This apparatus is flushed in a similar manner as the urinal by means of an automatic flushing cistern, and is so designed as to work effectually if used as a water-closet. Urinettes can be divided off separately, as in the case of trough closets, and each enclosure screened by means of a special hanging curtain, which may be drawn when in use and opened when vacant.

It is expected that the Government will announce the names of the Royal Commission on the Sewage Question within the next few days.

"PRACTICAL SMOKE PREVENTION."

By W. Nicholson, Smoke Inspector, Sheffield.

The smoke question, like the poor, is ever with us, and is a problem almost as difficult of solution. Much has been written on the subject, and from many pens a stream of more or less interesting and practical matter has flowed. All who have written have presumably been actuated by the very best of motives. They have realised the nature and extent of the evil, they have witnessed the blighting effect upon the beauty of our public buildings, they have observed how it has hung like a pall over our cities, hiding out the light of the glorious sun, and contaminating the air with the particles of dirt, and how it has crippled the health, and shortened the lives of the crowded workers in our great centres of industry. All this they have seen, and it has moved them to put pen to paper in the hope of doing something towards remedying it. The question at issue is very plain. Can the smoke evil be remedied? Is there any reason why we should continue to live in an atmosphere thick and black enough to resemble "acres of crape," as Charles Reade long ago put it? To this last question I give an answer in the negative. The evil can and might be cured. In making this statement I base it upon a lengthy and practical acquaintance with the subject—an acquaintance of a twofold character. In the first place, I had prior to 1890 a long experience of almost all kinds of boilers and furnaces; and, in the second place, I have since 1890 been Smoke Inspector for the City of Sheffield, a place which has above all others suffered from the ravages of the "smoke fiend," and which is known the world over as the "city of smoke and steel." My duties as Smoke Inspector have brought me in daily contact with all kinds of working conditions, appliances, methods, means, and men whose object has been smoke abatement; so with such an exceptional and practical experience I am entitled to give utterance to a few practical suggestions on smoke prevention. My aim in this pamphlet is to address, in a few short simple sentences, all persons who are interested in this question, but more especially do I speak as an engineer to engineers, engine tenters, boiler firemen, and furnace firemen. To these I would say that smoke prevention is entirely in their hands, in spite of any appliances, automatic or otherwise. I trust, therefore, that those who have such power placed in their hands (and at whose mercy manufacturers are) will give these pages that consideration which they deserve, and it will be my endeavour to make them a useful little handbook full of practical, sensible suggestions and rules for those in charge of boilers and furnaces; and I feel confident in saying that if put into practice they will make each man a public benefactor by stopping a nuisance, and making the condition under which the poorer people live healthier and happier.

SMOKE FROM BOILERS AND FURNACES.

As far back as 1819 smoke from boilers and furnaces was considered a nuisance and prejudicial to public health; and people began to inquire, experiment, and ascertain if it were practicable to prevent it. Commissions of inquiry were appointed, which laboured long, but with very little beneficent result. The question became a public one, and as years rolled on the interest in it increased, and resulted in Acts of Parliament, made with the idea to compel as far as practicable its prevention.

SHADES OF SMOKE.

There are many shades, colours, and densities of smoke. The Admiralty has prepared a "Smoke Form," which deals with the various kinds and colours of smoke, as emitted from the different kinds of manufacturing chimneys, viz., black, dense black, thin black, brown, dense brown, dark brown, light brown, bluish cast, and orange or yellow, dense and light; in fact, there are so many colours they are too numerous to mention. Some writers, lecturers, and speakers on smoke say that all smoke is a nuisance, and can be practically prevented. To such I would say, that their knowledge of the matter is not practical.

What does the Public Health Act of 1875 say on the subject? In Section 91, "Any chimney not being the chimney of a private dwelling-house, sending forth *black smoke* in such a quantity as to be a nuisance, shall be deemed a nuisance, and dealt summarily with, as provided by the Act." The same section also says, "That all furnaces and fire-places must be so constructed as to consume, as far as practicable, the combustibles used, without interfering with the said trade or process carried on therein."

So we have it here plainly laid down by law, that black smoke in such a quantity is a nuisance, and is punishable by penalty; and other smoke in the eyes of the law is not considered a nuisance. Black smoke, then, must be prevented from all kinds of furnaces as far as practicable, the onus of proving impracticability resting upon the defendants. It will be well for us to keep the law on this question in our minds, so that when we speak of practical smoke prevention in the following papers, we shall mean *black smoke*. We have black smoke in our midst; the Health Act says it is a nuisance, and persons creating the said nuisance can be punished by penalties, if they do not do all that is practicable to prevent it.

We are now called upon to consider the *causes of black smoke from boilers and furnaces*. The causes are many, and as varied as the conditions under which trade is carried on. But let us notice a few of them, and by examination find the cure, then the effect (black smoke) will quickly disappear.

Ignorance. — I do not desire to say a single hard thing against anyone who has such difficult duties to perform; what I shall say will be in all kindness, my aim being to throw a little light on the subject, and help rather than hinder in the way of smoke prevention. In this age, after so much agitation on the subject, writing in the Press, and talking on the platform, one is greatly amazed, when in contact with masters, managers, and men, to find in many cases their entire absence of knowledge on the common law of combustion. The explanation is simple from the masters' and managers' point of view; they are too busy in business matters to even give it a thought. The men who have charge of this work, and whose desire should be to obtain all information possible on the matter, never give it a thought. "Where ignorance is bliss," he thinks it a "folly to be wise,"

and from day to day he goes on in this condition of contentment, satisfied in a certain sense, that nothing more can be learned, that he is doing everything that can be done, until the Inspector points out how easily it can be prevented. Then he wakes out of his dream, and wonders why he didn't see how simple it was, under most conditions, to prevent it. Thus this lack of knowledge of a few simple rules which must be observed to ensure complete combustion is one of the greatest causes of black smoke. These rules we shall deal with later on.

Idleness.—Laziness is largely responsible for a lot of smoke. To prevent it means a little extra exertion on the part of the fireman, and this extra many will not use, unless continually watched; not like the other class, he knows what ought to be done, but hasn't that interest in his work to do it. He has a greater liking for sitting, reading, or rambling about, instead of giving that attention to the fires they require. How does he find time for the things named? By allowing too long a time between the firings, then putting three times more coal on the fires than he ought, and with what result?—(1) It takes a long time to burn through; (2) wastes the fuel; and (3) makes dense black smoke. This is not done through want of knowledge, but because of laziness; and there are far too many of this class of firemen, who are continually getting their masters into trouble by making preventible smoke.

Indifference.—Then there is another class of men whom we continually come in contact with in charge of boilers and furnaces, and whom we might call the indifferent. We cannot say this class is without knowledge — *re* smoke prevention — neither can we justly call them lazy, yet they seem to be unconscious, or unconcerned about their responsibilities. They are cautioned by the Inspector, and threatened dismissal by the master, but they go on in the same old style (after a few days), forgetting to watch the chimney when firing; never read paper or pamphlet on the question, never ask themselves why smoke is made, and how it might be prevented; they go on from day to day, and year to year, not caring anything at all about smoke prevention, but rather inclined to believe (as all firemen used to believe) that if they make black smoke, they are making a lot of steam. In my daily rounds I have met men with many years of experience, who have said "they cannot make steam without making black smoke." It is difficult to teach men of this class a little common sense in the way of firing. When they are shown how to generate steam quickly with less fuel and no dense black smoke they hardly will believe it, and drift into their old habits of indifference again. The only way to cure such indifference and foolish firing, is to make them pay the costs and penalty imposed for breaches of the Public Health Act. Do not think for one moment that I desire to put on the shoulders of the fireman all the blame for the emission of black smoke. He has, in many cases, the whole of the power in his own hands to prevent it; but in very many instances he is powerless to prevent, try as he will, because his

DRAUGHT IS DEFECTIVE.

What is the cause of defective draught? Small, cramped flues in a low chimney, and the boiler so built in that almost all air is entirely excluded from going through the boiler. With what result? Sufficient heat cannot be generated to cause combustion of the gases, the fires are sluggish, and black smoke is made. The fireman may do his level best to try and prevent it, but all to no purpose, because the draught is defective. These conditions are not uncommon, but far too common, and cause much black smoke, for which the master and not the man is responsible.

(To be continued.)

CONTROL OF PUBLIC WATER SUPPLIES.

It will be remembered that when, during the recent outbreak of enteric fever at Horsforth, it was alleged, as it was subsequently proved by a Local Government Board inquiry, that unfiltered water from a hillside, habitually manured with human excrement, was used to supplement the public supply, the directors of the company curtly refused to permit the inspection of their collecting grounds, or, in their own words, to "brook any outside interference with the management of their works;" and, indeed, the companies, including the Water Committees of Sanitary Authorities, acting in that capacity, display the same jealousy, the private companies refusing to recognise any right on the part of the Sanitary Authorities of the districts they supply to inquire into the modes of collection and of purification of the water that their constituents are compelled to drink, and the Authorities which themselves undertake this function, delegating the conduct of the works to the surveyor, the municipal engineer, or, perhaps, to one whose duties are exclusively those of a superintending and resident engineer, regarding the interference of the Medical Officer of Health as an unauthorised intrusion into a department with which he has no concern. We do not deny that a really competent engineer is fully capable of judging of the purity of the water as collected, and of the efficiency of the filtering processes, if he choose to study the subject; but it is equally certain that he cannot have the thorough apprehension of the relation between the water supply and water-borne disease, of the influence of impurities specific or indifferent on the public health, and of the means by which diseases, the bacteria of which exist out of the human body, are propagated and diffused, as one who with a medical training and a knowledge of the true significance of water analysis and a practical acquaintance with bacteriological research, has made a special study of the questions involved.

The Local Government Board intends, as we have reason to believe, to insert in all new water Bills promoted by private companies a clause empowering the Sanitary Officers of the districts interested to enter at all reasonable times for inspecting the methods of collection and of purification, but this will not meet the case of the more numerous existing companies. We are, therefore, pleased to learn that Dr. Porter, the energetic Medical Officer of Health for Stockport, to whose efforts this resolution on the part of the Central Authority is, we believe, due, has induced the Council of his borough to invite the Authorities of all districts at present dependent for their water

supply on private companies to join in memorialising the Government to pass a short Act empowering every Sanitary Authority supplied by a water company not being itself a Sanitary Authority, to depute any duly appointed officers, presumably the Medical Officer of Health and Engineer, "to enter, inspect, inquire, and take samples at any part of any source, or works of water supply, or water purification at any time by day or night," and requiring such company, "to afford all reasonable facilities and information for such inspection, inquiry, or sampling." Such a Bill need not extend beyond two or three clauses; it would not involve any financial question or introduce any conflict of Authorities or jurisdiction, or other contentious matter; and the only opposition it could provoke would be from the representatives of water companies interested in the concealment of actual or possible abuses. The memorialists very properly point to the fact that the consumers of flesh, milk, and other articles of food are more or less protected by legislation, and that such safeguarding is even more urgently required in the case of water—a necessary of life—of which the companies enjoy the monopoly, while the consumers are entirely at their mercy.

THE ISOLATION OF INFECTIOUS DISEASES.

By Dr. J. H. GARRETT, M.O.H., Cheltenham.

THE one disease above all others which contributes most cases to the filling of isolation hospitals is scarlet fever. In fact, in many towns and places no provision is made for the isolation of any infectious diseases besides scarlet fever and small-pox, and as the latter disease is now only an occasional visitor, the isolation of infectious diseases resolves itself in those places into the isolation of scarlet fever almost simply.

That the segregation of infectious persons should be limited in this manner to one or two diseases is not in accordance with the ideals of the sanitarian, but one may conceive that in many districts at least, the difficulties attending the discovery and removal of cases, as well as the great expense involved in retaining them in hospital till free of infection, are sufficient to bar the possibility of isolating more than a moiety of the infectious cases that occur. Thus the isolation of enteric fever and diphtheria has not been attempted in many districts otherwise than in an irregular or casual way, although the advantages of an early segregation of such dangerous infectious disorders is too patent for argument.

So far as I am aware, no attempt at all has been anywhere made to systematically isolate measles and whooping-cough, which are diseases that annually claim many thousands of victims, chiefly children of tender age. The great numbers of cases which in epidemic periods are liable to occur preclude the possibility of adequate hospital accommodation being provided in the case of the two last mentioned diseases, although I may say in passing, that in my opinion the notification of them would tend largely to diminish the death-rate amongst such cases, and in some degree to limit their numbers.

In a population of some fifty and odd thousand lying together on a fairly distinct and circumscribed area, the opportunities of an effective isolation should be greater than in a larger or more scattered district, and the feasibility of such a contention is well illustrated by the fact of our having isolated in hospital 93 per cent. of the scarlet fever cases which occurred in the borough last year, the complaint being at times rather prevalent in one locality or another. I should like to be able to say as much for the diphtheria and enteric fever cases, and in regard to the former there is no reason why so much might not be said; but although special provision has now been made here for the isolation of both these diseases, I apprehend from one cause and another that we shall not, at least for some time to come, be able to remove to hospital so large a percentage of the enteric fever cases, one of the main reasons being the habit that medical practitioners have acquired of treating such patients in their own homes, and their reluctance to allow them to be sent away.

That enteric fever patients may be treated at home and no second case in the house or in any of the neighbouring houses occur is quite true, but the experience one has had of another case, or other cases, cropping up in the near vicinity of a first case, leads one to the opinion that it would be to the public advantage if most enteric fever cases were treated in hospital, where a routine system of disinfection of stools, &c., could be much more certainly carried out than is ever done in private houses, not to mention other advantages of hospital treatment.

Of course, for any hospital it is desirable that there should be a resident Medical Officer, but in the absence of such a provision patients are still infinitely better off in regard to their care and medical treatment than they would be in their own homes. In our own case the Medical Officer to the hospital lives on the same side of the town as that in which the hospital is situated, and is in communication with the hospital by telephone. Acting under general instructions of the Managing Committee of the hospital, he is able at any time to call in such medical assistance as he may require in any operation or for other purposes. Sister Isabel, the matron, was formerly a nursing sister in the hospital, and she has under her an efficient staff of nurses.

It is quite possible that the question of *cui bono* may arise in the minds of some of our guardians of the public purse when contemplating the removal of so many mild cases of scarlet fever to hospital, and the continuance of the disease in the town notwithstanding. But although one cannot hope that the notification and isolation of such a disease as scarlet fever, the cause of which is obscure in its nature and origin, will lead to its extinction, yet I think we have ample evidence to show that the number of cases occurring is limited, and what would have been a serious outbreak but for these measures, is often toned down into a very minor affair.

A teasing question connected with the isolation of infectious cases is the recovery of fees from the patients for maintenance in the hospital. Such recovery of fees is permissively authorised by the Public Health Act, 1875, but in the case of the very poor, the attempt to recover would not only be a hardship upon the patient or those responsible for him, but would be sure to lead to an objection on the part of the friends of the sufferer to the removal,

and under such circumstances it would not be possible to get half the cases into hospital. This practical difficulty has had to be met by an assurance, which has now come to be an understood thing, that poor people will not be called upon to pay anything for the maintenance and treatment of their cases.

I am strongly of opinion that no charge should be made for any case that is sent into hospital by the Medical Officer of Health on public grounds, and should suppose that if a person were sued in a Court for the recovery of these charges, and stated that it was neither his will nor desire that his child was sent into hospital, but that he yielded to the pressure of the Medical Officer, and permitted his child to go purely for the public benefit, as represented to him by the public officer, it would be doubtful justice if he were ordered to pay. Those who can afford it will naturally have their cases treated in the private wards, and for these, of course, payment must be made, but that is quite another matter.

A YEAR'S PROGRESS IN SANITARY SCIENCE.*

By Joseph Priestley, B.A., M.D., D.P.H., &c.

SEWAGE PURIFICATION.

The year 1897 will ever be memorable on account of the prominence given during it to the subject of the bacteriological purification of sewage. The personal experience of such an authority as Mr. W. J. Dibdin, late chemist to the London County Council, has been published to the world in a book on the "Purification of Sewage and Water"—a work dealing only with principles, but not the less valuable. The principle is established that organic matter is destroyed by microbes, which rapidly increase under favourable circumstances, *e.g.*, the presence of fresh air (or oxygen) to prevent putrefaction, and a suitable pabulum upon which the microbes can feed. Complex organic matters containing chondrin, gelatine, albumen, starch, &c., are broken up by these microbes, and simpler combinations of elementary bodies result, *e.g.*, the C becomes CO_2; the H, H_2O; and the N, N_2O_3 or N_2O_5 (nitrous or nitric acid). Nature's method of purification is simplicity itself, and brought about by small bodies (varying from $\frac{1}{5000}$ to $\frac{1}{25000}$in. in diameter), which are really plants, depending for their efficacy upon their life and activity.

The sewage to be purified is in the first place strained or screened, and then passed on to filters of coke breeze, crushed clinker, ballast, sand, gravel, &c., the value of the filters being twofold, viz., (1) as mechanical separators; (2), as oxidisers of organic matters, whether in suspension or solution, by means of living organisms. The presence of air is so important that these filters have perforated walls, so that the whole substance of such filters can be aërated in all directions and at all depths, and must be used so as to admit of definite periods of rest. Thus, each filter bed may be so arranged (as mentioned by Mr. Dibdin) as to take one hour to fill, two hours to rest full (whilst the microbes do their work), one hour to empty, and three hours to remain empty (so as to ensure thorough aëration), whilst its surface must be raked over daily. The index of efficiency of a filter is to be found in the amount of nitrites or nitrates to be discovered in the effluent—the more nitrites or nitrates the better filtration, and *vice versâ*. Indeed, this chemical examination of the *average* daily sewage and effluent is a *sine quâ non*, and shows the quantities of oxidisable organic matters, the nitrites and nitrates in the effluent, and the amount of matters held in suspension—such details being most useful in enabling a correct judgment to be formed as to the efficiency or otherwise of the purification process. Further, the quantity and nature of the suspended matters is obtained by collecting on a microbe-filter and examining; whilst the filter beds may be graduated from coarse grains, through fine grains, to sand, and the effluent (after passing through these) be passed over land. Such is the Barking and Sutton system of Mr. Dibdin.

The Exeter system (tried also at Yeovil), carried out by Mr. Donald Cameron, the Borough Surveyor, is on the same principle, viz., the biological purification of sewage, and is effected in closed tanks, wherein putrefaction plays a prominent part, and from which the effluent is passed over coke breeze filters, and then finally (if required) over land. During the past year an inquiry has been held by the Local Government Board at Exeter, and the result of such inquiry will be awaited with eagerness by all Sanitary Authorities interested in sewage purification, as the simplicity, financially and otherwise, of the biological system being admitted, all that now remains to show is whether or not it will work out as satisfactorily in practice on the large scale, as it has theoretically in the laboratory and practically on a small scale.

Cameron's method (Exeter and Yeovil) depends—at least at first—upon the action of anaërobic microbes, acting in the dark and in the absence of air in the so-called septic tanks; whereas Dibdin's method (Sutton and Barking) depends for its efficiency upon the aërobic microbes, acting only in the presence of fresh air and light (*i.e.*, oxygen). Cameron's method in the tanks becomes Dibdin's method in the filter—the former a reducing or deoxidising action, the latter a purely oxidising one, with the conversion of ammonia into nitrites, and finally into nitrates (the nitrous and nitric acids uniting with the bases present respectively). The filtering process in both requires a plentiful supply of oxygen, and to obtain this the filtration must be intermittent—a condition of things brought about, in Dibdin's method, by hand labour; but in Cameron's, automatically by a patented simple alternating gear.

It is clear, therefore, that, where this principle of sewage purification by bacteria is relied upon, the addition of antiseptics to the sewage is worse than useless—at least in so far as lime, carbolic acid, &c., are concerned, though Mr. Dibdin is of opinion that permanganic acid, which is simply an oxygen-carrier, and acts by destroying organic matter without killing the microbes mentioned above, may with advantage be added. Ordinary disinfectants simply exert an inhibitory action over the microbes, which are the useful little scavengers of sewage disposal, and require, if anything, rather to be helped by means of oxygen, fresh air, light or other-

* Abstract of article contributed to the *Medical Annual*, 1898.

wise, further details of which will be forthcoming as experience increases and the practical working of this bacterial system of sewage disposal is more studied. These useful and beneficent microbes must, of course, be distinguished from those that cause disease, and against which it is the duty of sanitarians to fight vigorously and incessantly; indeed, there is setting in a reaction amongst scientific workers on the question of germs or microbes, and the microbomania of a few years ago is disappearing, or at least undergoing modification.

The future of the bacterial sewage purification is assured, and sanitarians and others will look forward with anxiety and impatience to reports and further information on the subject—the year 1897 having simply seen the principle well established.

PUBLIC ELEMENTARY SCHOOLS AND THE SPREAD OF DISEASE.

The Local Government Board (Medical Department) have issued an important memorandum during the past year on the circumstances under which the closing of public elementary schools, or the exclusion therefrom of particular children, may be required, in order to prevent the spread of disease without causing any unnecessary interruption of the work of education. The Board points out that the closing of schools is a measure to be seldom enforced, except under circumstances involving imminent risk of an epidemic, nor even then as a matter of routine, unless there be a clear prospect of preventing the propagation of disease, such as could not be looked for from less comprehensive action. Article 88 of the Code of Regulations approved by the Lords of the Committee of Council on Education renders it compulsory upon managers to *at once* comply with any notice of the Sanitary Authority (or of any two members) acting on the advice of their Medical Officer of Health, either to close the school or to exclude certain children from attendance, with a view to preventing the spread of disease, or any danger to health likely to arise from the condition of the school, *e.g.*, insanitary or otherwise, with right of appeal to the Department, after complying therewith. This procedure is to be put in force chiefly for diseases that spread by infection *directly* from person to person, *e.g.*, measles, scarlet fever, diphtheria, whooping-cough, epidemic influenza, small-pox, rötheln, but also for enteric fever or diarrhœa, if necessary.

The importance of children from infected houses being excluded so as to prevent them attending school in a latent form, or in an unrecognised stage of the disease, or to prevent infection by clothes, needs only to be mentioned to be acknowledged; and as a rough working rule it may be stated that schools ought to be closed where there are many undiscovered or unrecognised cases, or when the known centres of infection are very numerous, and where too much intercommunication elsewhere than at school does not take place, more especially where exclusion of separate children is not successful owing to mild and unrecognised cases. Closure, it is to be remembered, is an extreme measure, however.

As some diseases are not notifiable to the Sanitary Authorities, it is important that the school attendance officers, and school masters and mistresses, should notify cases amongst scholars of infectious diseases and others, *i.e.*, the notification of absentees, and should look out for symptoms in epidemic times (*e.g.*, heat of skin, shivering, headache, languor, vomiting, rashes, sore throats, &c.), so that precautions may accordingly be taken in the way of excluding children from school, &c. The Medical Officer of Health is clearly the proper person to advise as to the precautions to be taken, length of time during which children are to be excluded from school, or schools closed, &c., and the Local Government Board have laid down that where schools are closed, the Medical Officer's reports to his Authority, stating grounds and reasons for closure, shall be regarded as special reports, and consequently copies shall be sent to them and to the County Council of the district within which the school is situated.

The above conditions apply only to public elementary schools, and not to Sunday or other private schools, these latter being dealt with under the Public Health Acts as contravened.

The issuing of this Memorandum is opportune at the present time, as the subject of the spreading of infectious diseases through the medium of schools is coming rapidly to the fore, and statistics are fast accumulating which show that such inter-relationship between infectious diseases and schools does exist. Such statistics may be necessary to convince the lay mind, but are hardly needed for Medical Officers, who, if of any experience in practical sanitary work, must have had many opportunities of proving for themselves the truth of such inter-relationship.

The examination of scholars individually and the exclusion from schools of those suffering from, or sickening for, an infectious disease, together with the other inmates of the same house, with a systematic notification (and subsequent medical examination) of *all* absentees to Health Officers are important steps towards the prevention of the spread of disease, and may prove all-sufficient in the case of some, though school, or class, closure is certainly indicated, and required, in the case of others, of the infectious and contagious disorders, and under the conditions as stated above.

(*To be continued.*)

SOIL CONDITIONS: THEIR PRACTICAL RELATIONS TO INFECTIOUS DISEASES.

Dr. W. H. Welch, in a recent issue of the Baltimore *Health Magazine*, discusses the fate of pathogenic organisms which find their way into the soil. Although the nature of the relationship between the conditions of the ground and the prevalence of tuberculosis is not well understood, practical experience has shown that many localities have secured, by good drainage of the soil, great reduction in the mortality from this most deadly scourge of the human race—a reduction amounting in some places to nearly 50 per cent. of the former death-rate. Similar measures in Berlin and elsewhere have notably lowered the mortality among infants, particularly from summer diarrhœa. Having once reached the soil, disease-producing germs may be conveyed to us in manifold ways. An important medium of transportation of bacteria from an infected soil is the water which we drink or use for domestic purposes. Among the various other ways by which harmful bacteria may reach us

from contaminated ground it will suffice to specify their conveyance attached to particles of dust in the air, their transportation by flies and other insects, and by domestic animals, their presence upon vegetables, especially those eaten uncooked, and our own direct contact with the soil.

It is evident that the possibilities of infection from soil contaminated with disease germs are numerous and often intricate. The list of diseases whose causation has been shown to stand under certain conditions in more or less direct relation to contamination of the ground with their specific germs is a long one. Among the more important may be mentioned malaria, typhoid fever, cholera, yellow fever, dysentery, tuberculosis, and the summer diarrhœas of infants. Experience teaches, unmistakeably, that contamination of the soil with organic refuse favours the development and spread of such diseases as these, and that the drainage and purification of the soil by proper systems of sewerage are among the most effective measures for their prevention.

No more instructive illustration of the value of modern methods of public sanitation can be found than the inability of Asiatic cholera to secure a foothold during the last two European epidemics in clean cities, with proper sewerage and water supply, and its ravages in notoriously filthy or insanitary cities, such as Toulon, Marseilles, Naples, and formerly Hamburg. Authorities have differed as to the relative value of sewerage and of water supply in influencing the prevalence of typhoid fever. We need not pause here to discuss this matter. Both factors are important, the drinking water usually the more important. But it is sufficient for our purpose to show that purification of the ground by proper disposal of sewage is one of the factors in determining a reduction in the occurrence of typhoid fever and other diseases.

It is by no means an easy matter in all cases to assign to each one of the various recognised elements which go to make up an entire system of satisfactory municipal sanitation its due share in the beneficial result, for it rarely happens that one is introduced by itself alone, and the harmonious working of the whole system is often necessary to secure the best results from the individual factors such as pure water supply, efficient sewerage, good drainage, cleanliness of streets, improvement or removal of insanitary quarters, thorough sanitary inspection of dairies and food stuffs, public disinfecting establishments, hospital for infectious diseases, municipal laboratories, &c. In some instances, however, the conditions have been such as to furnish conclusive demonstration of the separate influence of the introduction of effective sewerage upon the death-rate from typhoid fever.

TO OUR READERS.

The Editor solicits the co-operation of readers in making THE SANITARY RECORD *more attractive by means of pen-and-ink sketches, photographs, and diagrams. There are many phases of sanitary work which lend themselves admirably to illustration. By this means not only individual articles, but the journal as a whole will be heightened.*

TYPHOID FEVER: IS LONDON SECURE AGAINST OUTBREAK?

By Dr. HENRY KENWOOD, M.O.H., St. Mary's, Stoke Newington.

THE problems connected with the life-history of the bacillus of typhoid fever outside the human body are now being scientifically attacked, and recent work by Lösener, Martin, Pfeiffer, Kolle, Robinson, and others, tends to establish the view which is supported by so much circumstantial evidence, that polluted soil is the great medium in which the germ thrives; and the fact that the death-rate from typhoid fever in this and some other countries has been markedly reduced during recent years may safely be attributed, in the main, to two circumstances, *i.e.*, firstly, that the pollution of soil has generally been diminished; and secondly, that the increased precautions taken of late years to guard our drinking water and milk from pollution have had the effect of materially reducing the extent, by spread, of a filth disease which is so frequently water or milk-borne.

To reduce typhoid incidence every effort must be made by the proper sanitary control of encampments of itinerants, &c., and by the abolition of leaky and defective drains, cesspools, midden-pits, &c., to guard the soil—more especially that around houses and in the neighbourhoods of collecting areas for drinking water—from an infection which may doubtless grow and remain active in such soil for long periods under certain favourable conditions; and the possibility of water acting as a carrier must be removed in the only certain way, *i.e.*, by going to a pure source for a pure supply, and sparing no pains and expense to guarantee the continued purity of the water from the site of its collection until it reaches the consumer.

The principle of attempting to purify a polluted water is wrong if it can possibly be avoided, and, having regard to the tremendous issues at stake, indefensible. Purification through sand, for instance, is at best imperfect and by consequence dangerous, for our methods of detecting the infectious power of water, where typhoid is concerned, are still very unreliable; chemical and bacteriological examination may both fail, and even if the latter succeeds, the information can rarely be furnished under a week; and think of the mischief which may, and does, result in the meanwhile. Our only real safety lies in selecting a pure water supply, and in keeping it pure. Typhoid fever can only become markedly epidemic in this country when the infection gains access to a widely-distributed carrier, such as water and milk, and this circumstance sufficiently indicates the main lines of our defence against the disease. The recent outbreak at Maidstone has set every Authority a question to answer—What security have they that the means adopted to protect their district from such an outbreak are sufficient? In London every thinking individual must have his misgivings. The purity of a water supply must always be measured from the standpoint of the worst sample distributed; and, especially in time of flood, the drainage areas of the Thames and Lea furnish considerable pollution to the river waters, and a sand filter is asked to protect London from the almost constant danger of water-borne disease. Certainly the death-rate from typhoid fever is low for London, but as

Professor Corfield and Mr. Shirley Murphy have shown, there is an exceptional incidence of the disease in those parts of London supplied by Thames water during flood time, and the chemist to the London County Council and the bacteriologist to the Local Government Board have demonstrated that, at these times, living animalculæ, considerably larger than the typhoid germ, may pass through the filters into the filtered water.

In non-epidemic periods a considerable number of isolated cases crop up in every community, the cause of which can only be conjectured by the Medical Officer of Health, and in which it is very exceptional to be able to trace the infection to a preceding case; but when the infection is traced to a preceding case we are no nearer the scientific truth of the real origin of the infection itself. How did the preceding case contract it? There is undoubtedly a great difficulty in arriving at the probable cause of these sporadic cases, and this is largely due to a fact, *i.e.*, that in the majority of cases one learns, on inquiry, that the patient was ill or ailing for several weeks before the condition was diagnosed, and in consequence it is impossible to determine the actual period of infection with any degree of precision, and therefore to hit upon its most probable cause. The origin of these isolated cases is very generally a matter of pure conjecture; the tendency is all too common to ascribe the cause to any marked insanitary condition of drainage and water supply noticed when the house is inspected. That such are concerned in the appearance of the disease is, to my mind, unquestionable; but since almost every house in this parish, when house-to-house inspected, was found to present one or more such insanitary conditions, and the sickness from typhoid fever gives no indication of a material reduction as these conditions are removed, it cannot be held that when in one of such houses a case of typhoid fever occurs, the condition is certainly due to the insanitary conditions which may be found. We must not rest content with those sham investigations which are satisfied with the mere discovery of a preceding case, and which conclude, haphazardly, that one of those insanitary defects which exist in so many houses is necessarily the cause of the infection, though drain and sewer gases certainly contain poisonous substances, either of the nature of gases or vapours, which strongly predispose those subjected to them to disease in many forms—among which one may safely include typhoid fever and diphtheria.

A SPECIAL meeting of the Bangor Town Council was held recently to consider a letter from the Local Government Board, refusing to entertain an application of the Council for sanction to a loan of £450 for the purchase of land adjoining the gasworks until a definite scheme for the utilisation of the land was submitted. It was resolved to direct the Town Clerk to ask the Board to reconsider the matter in view of the straitened circumstances the Council was in with regard to the gasworks, and also to ask for permission to open a suspense account, so as to complete the purchase of the land, pending the Council being in a position to present the definite scheme asked for.

THE SANITARY INSTITUTE.

SUPERVISION OF WATERSHED AREAS.

A SESSIONAL meeting of the members of the Sanitary Institute was held on Wednesday, 6th April, at the Parkes Museum, Margaret-street. Professor G. J. Symons, F.R.S., presided, and there was a good attendance.

Mr. R. E. Middleton, M. Inst. C.E., read a paper on "The Desirability of Making Watershed Areas and Sanitary Districts Coterminous." He quoted the opinion of Major Flower, expressed at the Leeds Congress, in favour of the division of the country into watershed areas for purposes of water supply and drainage, which areas should be made coterminous with the sanitary districts. Streams and rivers, he said, from the earliest times had been put to different and antagonistic uses. They had been considered to form the natural source of supply of water for drinking and culinary and ablutionary purposes, and at the same time to be receptacles for all animal, vegetable, and mineral refuse. It had even been maintained in quite recent years that the latter is the

NATURAL AND PRIMARY DUTY

of every stream or river. But the first use of a river, from the sanitarian's point of view, was to provide water for animal life; and, secondly, it might provide power for milling or manufacturing purposes; thirdly, it might be used for carrying persons and property; lastly, and not until the other requirements had been satisfied, it might be used in such a manner as not to defeat its primary obligations, for the removal of refuse matter. In every direction, however, the tendency to pollute streams and rivers, was, from a variety of causes, on the increase, at the same time that a demand for a supply of pure water was likewise increasing, while the area from which a supply might be safely drawn was diminishing. Many rivers had become impossible as sources of water supply on account of the trade refuse passed into them. Undoubtedly, the pollution most dangerous to man was that produced by man himself. The untreated excreta of the human being were at all times a source of danger, but when they proceed from a diseased human being they may carry with them the germs of death to many fellow-creatures, and with the increase of population came increasing difficulty and increasing costliness in dealing with the refuse—animal, vegetable, and mineral—which results from human aggregation. It seemed doubtful if any danger was to be feared from the droppings of cattle when living in the open, and even if they were to some extent dangerous, they were necessarily limited in quantity, for cattle cannot live in an area which will not easily disinfect all the manure they produce.

ARTIFICIAL MANURES,

such as guano and fish in a putrid condition, were much more to be feared than any natural manure. The available water supply was also becoming more limited on account of the amount of land which is occupied by towns, villages, and manufacturing centres, while the increase of population, the demands of a higher civilisation, and the greater requirements for steam and similar uses, all call

for a greater supply, and a more liberal use of water. Consequent on the increase in the size of our large towns, the demand for water had led to an upsetting of all preconceived ideas as to the sources from which supplies should be obtained. Manchester obtained a supply, not from its own district, but from Cumberland, Liverpool from Vyrnwy, Birmingham from the Elan Valley, and the London County Council would have us look to the valleys of the Usk and Wye for the metropolitan water supply. There did not appear to be any efficient conservation of the sources of supply for the use of those who were the natural heirs to it, viz., those who are the first to receive it from the atmosphere, and at whose feet it is running, either above ground in the form of streams and rivers, or below ground in tiny rills. Every town and village situated on the banks of a river or one of its tributaries had a vested interest in the maintenance of the purity of the water which flows towards it, and at the same time the town or village desires to discharge its refuse into the stream, making it a nuisance to its neighbour lower down. The protection afforded to consumers by

NATURAL PROCESSES OF OXIDATION

and the action of vegetation and sedimentation were not sufficient unless they were supplemented by the power of an authority strong enough to curb the tendency of the human animal to get rid of the refuse he creates with the smallest amount of trouble and at a minimum of cost. The disposal of sewage was until quite recently a subject not to be mentioned to ears polite; suddenly sanitary science became a fashion, and much was done in a hurry which would have been done better if it had been longer thought over. Sewage disposal works in many places were practically useless, because the inhabitants had not the money with which to keep the works in order. In other cases sewage disposal works were conspicuous by their absence. The selfish policy of turning all refuse into the nearest stream led to still greater pollution of the water supply as population and manufactures increased; the natural course of procedure which puts the provision of a pure and sufficient supply of water first and the disposal of sewage second was reversed, and the position became intolerable. Moreover, the earlier efforts of legislation were directed to the provision of sewage disposal, while omitting to require that this necessary stipulation should be preceded by

AN AMPLE SUPPLY OF WATER.

Subsequent legislation had inclined to leave the cart before the horse, and to subordinate any question of water supply to that of sewage disposal, making the latter compulsory and the former to a large extent permissive. The Rivers Pollution Act of 1876 was consequently very tender to vested interests, and entirely insufficient to curtail the increasing tendency to pollute. Considering the constitution of the Authorities which have to administer the Acts dealing with the provision of water supplies, with the disposal of refuse, and the pollution of rivers, it was scarcely to be expected that the result should be other than it is. All authorities had conflicting interests to consider, and it was easier to go outside their areas for a water supply than face the difficulties of dealing with the sewage which they must get rid of. In this manner enormous drainage areas were becoming useless for purposes of a water supply, and large towns had to tap distant sources at present unused and uncontaminated sources of supply. It seemed reasonable that each district should supply its own needs, both in respect to water supply and sewage disposal, but this could not be done unless a pure water supply was put first and sewage disposal subordinated to it by rigorously enforcing the obligations consequent on the aggregation of large bodies of men in centres of industry. If areas of water supply are to be efficiently safeguarded, if rivers are to be preserved from pollution, the present system of

DIVIDED AUTHORITY SHOULD BE ABANDONED,

and a general policy substituted. Having referred to cases in which districts had amalgamated for common purposes, Mr. Middleton gave some figures to show how many different Authorities were affected by the watershed areas of the Thames, Severn, and Ouse, in order that some idea might be formed of the conflicting interests existing in watershed areas under the present division of administrative districts. A further consideration, he said, which pointed to the necessity for having some Authority responsible for watershed areas, was that of floods. Many districts in England were periodically flooded, with disastrous results. The Rivers Pollution Act did not provide powers of sufficient stringency to enable the pollution of rivers to be dealt with efficiently, and certain Acts of Parliament, such as the Mersey and Irwell Acts of 1892, and the Thames Conservancy Act of 1894, had been passed extending the powers of existing Authorities. These Acts were, however, purely local, and it was desirable that their powers should be made general, and that an Authority similar to the Thames Conservancy Board, but with extended powers for raising funds, should have charge of the principal rivers of the country. In what manner the watershed areas should be mapped out, whether the existing boundaries of counties, sanitary unions and parishes should be adhered to, or whether there should be a re-arrangement of these artificial divisions, was too large a subject to be dealt with in that paper. The constitution of the proposed Authority was also a matter of great complexity, especially as regards the

QUESTION OF RAISING FUNDS,

but he thought it should be representative of every class and interest, and that its duties should consist in the conservation of the river, its banks and navigation, if any, in the maintenance of its purity, including that of its tributaries, in the encouragement of combination and efficiency in sewage disposal, and in the prevention of floods. (Applause.)

On the suggestion of the CHAIRMAN a hearty vote of thanks was accorded to Mr. Middleton for his paper, and Major Lamorock FLOWER, Mr. Baldwin LATHAM, Dr. A. HAVILAND, and others joining in the ensuing discussion, expressions of concurrence in the lecturer's opinions being general.

Mr. MIDDLETON, having replied to some of the points raised, a hearty vote of thanks to the Chairman, passed on the proposition of Mr. H. P. BOULNOIS, closed the meeting.

At an examination in Practical Sanitary Science, held in Birmingham on April 1st and 2nd, 1898,

our candidates presented themselves. The following two candidates were granted certificates in Practical Sanitary Science :—Walter Harry Woods, Richard Philip Fleming.

At an examination for Inspectors of Nuisances, held in Birmingham on April 1st and 2nd, 1898, thirty candidates presented themselves. The following ten candidates were certified, as regards their sanitary knowledge, competent to discharge the duties of Inspectors of Nuisances :—Bertram George Bannington, William Barnes, Guelph John Bird, Francis Charles Braley, Alan Bromly, Charles William Cooper, Thomas Gough, Thomas Hudson, Frederick Merrifield, Jonathan Nichol.

THE THEORY OF SANITATION.

In the course of a lecture, entitled as above, recently delivered at Boxmoor, Herts, Dr. Maitland Thompson said that the subject—"The Theory of Sanitation"—was too wide to be dealt with *en bloc*. What he proposed to touch upon principally was the modern treatment of sewage. His apology for introducing such a morbid subject must be in the first place—whether he mentioned the subject of sewage disposal or not—that for the next two years they would be constantly reminded that some great change was taking place in that district for the disposal of the sewage. The roads would be obstructed, and those of them who were ratepayers would be still further reminded, and in his opinion they would be put to a much greater expense than was necessary. He was well aware that the disposal of the sewage had puzzled Sanitary Authorities, more or less, since the Public Health Act come into force. A district like theirs presented peculiar difficulties, part of it being very low-lying and water-logged, and most of the land around being unfit for the reception of sewage. They were most of them probably aware that the Hemel Hempstead District Council had adopted a scheme for pumping the sewage of that district on to a tract of land, and at a level somewhat above the tops of the houses. That scheme was adopted as the result of the repeated threats from the Thames Conservancy, and of the pressure from the Local Government Board. The health of the district, however, did not demand the change. The percentage of zymotic or infectious diseases was by no means high as compared with thoroughly sewered districts, even at the present time. He did not wish them to assume for one moment that he disparaged a thorough system of drainage. On the contrary, he would advocate more thorough, more modern, and much less expensive methods than had been adopted in Hemel Hempstead. He described the conditions under which the sewage, by land filtration, could be fairly successful; but, he said, the site chosen there for the sewage farm was, on the evidence of all the experts who had examined it, unsuitable. Most of the land consisted of a few inches of soil spread over chalk. Chalk would, under certain conditions, swallow up endless quantities of moisture; but sewage matter introduced into chalk had been known to appear again miles away and pollute wells and water supplies. It was quite possible that the gathering ground of the Hemel Hempstead water supply was part and parcel of that land. There they were introducing a danger which did not at present exist, and in the near future they might have an outbreak of typhoid —or some similar malady—due to polluted water, of which Maidstone had recently afforded such a glaring object lesson. It had been recently proved that the germs of certain diseases, such as that of typhoid fever, would remain active and multiply in the soil in the English climate for a year or more. These found their way into water supplies. In dry weather these germs might be distributed broadcast in the particles of dust that were driven by the wind, so that after incurring the constant expense of pumping, and the accidents and incidents attaching thereto, the sewage matter had still to be reckoned with. That the authorities in Hemel Hempstead should have been so suddenly rushed into a scheme such as they had adopted, without scientific investigation of other treatments and methods, had been a great surprise to many. Other Sanitary Authorities with an infinitely greater rateable value than theirs had had the sense and courage to say at once that that system was too expensive for them, even if it was the best that could be devised. The District Council of Hampton, for instance, more sorely pressed by the Thames Conservancy than they in Hemel Hempstead were, and situated as they were on the Thames, had adopted a bacterial treatment of sewage in tanks. When he ventured some twelve months ago to suggest a similar treatment (the outlines of which were most ably traced out and explained by one of the greatest authorities of the day on the subject) to the District Council, he received but scant attention. The Council sat, watch in hand, and gave them ten minutes in which to explain—as though they were seeking paltry outrelief. They sought a vast relief—not only a personal one; but they sought to relieve the rates of some thousands of pounds, and they all knew what that meant in a poor district like theirs. He personally on that occasion advised the Board to do what the city of Exeter did in November last—apply to the Local Government Board for borrowing powers on a bacterial system, with a minimum amount of land to meet the requirements of that Authority. They had enough land at Frogmore End for the purpose. He trusted that it was not too late, even at the present time, for the Board to adopt a tank treatment and save them the constant expense of pumping, and the dangers he had indicated. The land at Bennett's End could be sold, and if it was a loss it would be better than being saddled with a constant sinking fund. He referred to the fact that a Royal Commission was to be appointed to investigate the subject of the bacterial treatment of sewage. The bacterial treatment was capable of popular explanation, and this would perhaps suffice, as it would be impossible for him to explain it in detail in the short time available. The destruction of organic refuse was naturally brought about by the agency of micro-organisms or bacteria, which were nature's scavengers. What nature did very slowly (as when sewage was cast upon the land) and imperfectly could be done more quickly and completely, with less danger and offensiveness, and at less cost by filters and tanks. It was not in the ordinary sense a chemical process. It did not consist, as some were disposed to think, in disinfecting or destroying organic refuse by means of chemicals. That process had been tried in the past and was a failure, simply because it was

contrary to nature; and it had delayed the introduction and adoption of the natural process until recent years. Dr. Thompson quoted the opinion of Mr. Dibdin (late chemist to the London County Council), who was strongly in favour of the bacterial system, and gave instances of its success. The bacterial treatment had succeeded when the sewage was distinctly a trade sewage; by that he meant sewage issuing from chemical, dye, and other works—the most difficult to deal with. In their district the sewage might fairly be described as a domestic one, and therefore the easiest of all to handle. He mentioned several towns in which the bacterial system was in operation, and in every instance acting to the satisfaction of the inhabitants generally. The lecturer referred to the conditions of life in days gone by, when the earth closets were used, and the sewage matter was left to nature's scavengers. Very soon the old-fashioned cess-pits would re-appear in the form of larger sized modern tanks and filters, according to the populations to be dealt with. Nature would then continue to do its work under the supervision of scientists. After having referred to bacteriology as a study, Dr. Thompson said that bacteria played an active part in the causation of nearly every disease, and a new system was being opened up in the treatment of disease as a result. As surely as the microbes that acted on the living tissue caused disease, destruction, and death, would those that attacked dead tissue entirely destroy it and render it harmless, effecting a great economy in nature.

A NEW TYPHOID PAN.

THOSE who have to battle with that most insidious of all diseases—typhoid—will appreciate the importance of completely isolating the excreta and other matter proceeding from the patient from any but the slightest contact with the outer air. Such desirable results may now be effected by the use of Hancock's patent typhoid pan, manufactured solely by the Winton Pottery Company, Elgin Works, Stoke-on-Trent. The pan under notice, which is being rapidly adopted throughout the country, is very portable in size, is cylindrical in form, with a holding capacity of about a gallon; it is made of stout cream-white earthenware of such a thickness that breakage is well nigh impossible; it has a lip to facilitate emptying, and has two wide grooves within the pan—the lower one to receive the cover, and the upper one has three indentations for the manipulation of the interlocking device. The cover, which is the principal part of the patent, is fitted with a broad band of vulcanised rubber, adhering by elasticity to a verge adapted for the purpose, the rubber being rendered thoroughly antiseptic by a special chemical treatment. The interlocking arrangement, by which the pan is rendered "gas tight," consists of a tripod, operated upon by a milled circular screw, securely cemented in an aperture penetrating only half through the cover, thus involving not the least contact with the outside air; by the merest turn of the wrist, pressure is brought to bear on the cover, and the pan becomes hermetically sealed. There is not the least risk of leakage or unpleasant effluvia from the contents, no matter in whatever position it may be handled, or the length of time that elapsed before the contents are taken away for incineration purposes. The Local Authorities in the towns surrounding the place of manufacture have grasped the value of this typhoid pan, and it is now universally adopted by them, not only within the municipalities, but in the more remote suburban districts. A specimen of the pan has been submitted to us for inspection, and we unhesitatingly pronounce it an appliance of great value from a sanitary standpoint.

Annotations from Annual Reports.

Are Model Dwellings Unsanitary?—This question is answered in the affirmative by Dr. Joseph Soane, Medical Officer of Health, Whitechapel, who, alluding to examples in his own district, states:—"That the direct influence of these barrack dwellings upon the health of their occupants—more especially of the children—is adverse, I have not the slightest doubt. I have reason, moreover, to believe that the spread of zymotic diseases is aided by the general plan of construction adopted in dwellings of this class. A staircase leading to a corridor, which affords access to many rooms more easily facilitates the spread of disease than in the case of tenements which are more separated. It may also be said that as the staircases and passages frequently have to constitute the playground of the children, another factor is imported to account for the spread of disease. I have collected evidence which supports my opinion that both scarlet fever and diphtheria evince a marked tendency to appear in families who occupy rooms which are adjacent to other rooms where the disease has already appeared. Small houses, with rooms which can be entered from independent staircases commend themselves to my mind as far preferable from many points of view, as dwellings for the working classes; it is certain, however, that owing to the increasing value of land in the metropolis this desideratum is not yet to be attained. The height, too, of these modern model dwellings stands in the way of furnishing them with a constant supply of drinking water. The water must therefore be stored in cisterns of sufficient capacity to supply all but the lower floors, and this arrangement certainly is not in the direction of improved sanitation. In times of drought other and more serious inconveniences occur. Small children are not given the chance to breathe as much fresh air as they require, and they do not reap those advantages obtainable from sunshine which are absolutely necessary to ensure them becoming healthy men and women. I feel that my contention will be eventually demonstrated, and that the time will come when many so-called model dwellings will be condemned."

CHELSEA.—Mr. John Humphrey, chairman of the Bath Commissioners, recently opened the new baths and washhouses which have been erected by the commissioners at Kensal Town at a cost of £27,000. The building contains two swimming baths—one 80ft. by 30ft., and the other 60ft. by 25ft.—a large number of private baths and a laundry, with offices for the staff.

THE VITALITY OF PATHOGENIC GERMS IN DRINKING WATER.

By Dr. B. Meade Bolton, Princeton, U.S.A.

One of the most striking features of the bacteria is variability. These organisms are subject to variability of shape, of all these vital manifestations, such as fermentation, production of disease and of pigment, in the capacity of living in various media. They possess no characteristic not subject to variation. The anthrax bacillus—ordinarily a short, sharply-cut rod forming spores or resistant bodies under favourable conditions, and capable of producing a virulent infectious disease in man and animals—sometimes becomes so distorted in shape as to be unrecognisable under the microscope. It may be made to lose its power of forming spores and of producing disease. The diphtheria bacillus is sometimes a fine uniformly-stained rod; at others it appears as a large irregular nodular rod. Sometimes both ends are swollen and apparently distorted, sometimes one end alone. Again, the rod stains irregularly; the protoplasm is collected into clumps and granules in the cell membrane. The bacillus prodigiosus frequently resembles a coccus, and at others appears as a distinct rod or even a short thread. This organism, which ordinarily forms a deep red mass on the nutrient medium, frequently loses its power of producing pigment. Percy Franklin has found out that with certain bacteria it is possible to force them to produce certain products of growth by gradually introducing certain substances into the nutrient medium. I have found that the bacteria may be accustomed gradually to the presence of substances in the nutrient medium that would be sure to destroy or inhibit the growth. There is even evidence that the bacteria may be finally stimulated to increased growth by the gradual introduction of substances classed as germicides. But it is useless to multiply examples. The variability of the bacteria under the influence of external conditions is well recognised, and the sensibility of these to environment has been abundantly shown. This property must be ever borne in mind. It must not be forgotten that the bacteria are lining cells, and not chemical compounds. All cells have more or less individuality, and all agglomerations of cells have variable characteristics. This can be illustrated by any series of experiments with disinfectants. The use of a certain amount of the disinfectant may destroy many of the organisms, and yet leave many more unaffected. The same amount of the disinfectant may kill more of the organisms in one culture than in another. Hence we cannot wonder at the vitality of the bacteria in water. The typhoid fever bacillus has been found to live for thirty days in water into which it was introduced intentionally, and yet it is frequently found to die out much sooner than this in water.

In many experiments I have endeavoured to arrest the vitality of various pathogenic bacteria, and the discrepancy in results was a surprise and a disappointment. Sometimes they diminished and disappeared much more quickly than at others. Yet this is not to be wondered at. There are many factors that determine how long they are likely to remain. The number introduced, the special adaptability to water of those that are introduced, the temperature of the water, the number of other kinds of bacilli present, all are factors in the play. Again, the amount of organic matter that could furnish a supply of nutrition might be a factor. I have always found that pathogenic bacteria introduced into water disappear sooner or later. They do not multiply even in foul water from a shallow well, and fail even when this water was freed from other bacteria that is sterilised. I have been able to obtain a multiplication in water only after adding a certain amount of peptonised beef broth. It is necessary to add an amount of broth estimated to contain 67 milligrammes of organic matter to a litre of water before any growth can be obtained of typhoid bacillus, and the equivalent of 400 milligrammes of organic matter before any multiplication of the cholera organism can be obtained. This amount of organic matter is never found in the most contaminated water, and not only this, but the kind of organic matter used in the experiments is not found. What is found ordinarily would be less suitable for the typhoid and cholera bacilli than the carefully-prepared peptonised broth used in the experiments, and it may safely be stated that where water becomes contaminated with pathogenic bacteria these will disappear rapidly owing to lack of proper nutrition and to the conflict of other bacteria, the saprophytes, found always in contaminated water. There are bacteria that multiply even in distilled water, and these are the aquatic bacteria which quickly make the pathogenic form disappear. The latter are very choice in their food. We must prepare the media for their cultivation with great care, and they stand no chance in competition with the hardy saprophytes found in water. The pathogenic must be given conditions closely resembling those of the animal body to grow and multiply; the saprophytes, on the other hand, flourish at a lower temperature and with less elaborate food. This is the reason why the examination of water shipped to the laboratory is of no use. In a few hours it is changed as to its flora, some abundant at first are less so; others, few at the start, increase often enormously. It is an interesting experiment to examine water freshly caught, let it stand and examine at intervals. About two forms usually survive and increase very rapidly. One is a bacillus fluorescent, non-liquefacient, and a micrococcus, to which I gave the name micrococcus aqualilis. For this reason it is never worth while to attempt an analysis of shipped water.

Results are misleading. The danger from contaminated water arises from the use of the water very shortly after contamination. Of course, if there is a source of continuous contamination, then the water is dangerous at all times, and the organisms are easily found, as during the cholera epidemic at Hamburg and Altona. In case of typhoid the matter is peculiarly difficult and time-consuming. Again, another difficulty is the want of definite characteristics of typhoid bacilli themselves. The matter of contamination of water with this form is of more importance to us in this latitude, and it would be of the greatest value to be able easily to recognise this organism. Satisfactory results are not obtainable without the expenditure of a great amount of work and many precautions in the collection of samples, and immediately making cultures. I question the utility of one examination. A well may be free and con-

taminated at different times. The chief if not the only danger arises from surface contamination. If water filters through a soil it is purified. Now, during a dry season, there is little danger from the surface drainage. Only in case there is a crack or crevice leading from a privy vault or other source of contamination is there great danger of infection. Esmarch has shown that pathogenic bacteria rapidly die out in the soil within one or two days, so that it would be a difficult matter really to make the bacteria pass from a privy vault to a well through soil in which there are no crevices. Flugge is of opinion that infection of water is more apt to take place indirectly than directly. He does not deny any more than others that what the Germans call *massen infection* takes place from drinking water. In the case of typhoid fever Dr. Bolton always believed that danger of spreading the disease arises as much from indirect contact of food and vessels for food and drink, with the typhoid excreta, as from contaminated water. Finally, pathogenic bacteria usually have a brief life in water; under ordinary conditions multiplication and growth are not favoured; the danger of the spread of the disease in this way is transitory unless the source of contamination is continuous, as from a channel leading from a privy vault. Water is probably infected frequently after it is drawn and carried into the house for use just as food probably is.

Reviews.

Model Regulations and Bye-laws for the Drainage and Plumbing Work of Buildings; with Notes and Illustrations. Prepared under the supervision of the six District Councils in Scotland for the National Registration of Plumbers, and ordered to be published by the Congress held at Perth, 1897. Glasgow: James Walton and Co. 1s.

THE publication of this excellent little book is especially opportune at the present time. The new Public Health Act for Scotland came into operation on January 1st last, and under Section 181 of the Act Local Authorities in counties are for the first time empowered to make bye-laws relating to the construction, drainage, and inspection of all buildings in the districts under their jurisdiction. Such powers have long been possessed by the principal towns under their local Acts of Parliament, and the general Burgh Police Act conferred similar powers on the Commissioners of all Police Burghs in Scotland in 1892; so that the present provision of the new Public Health Act merely extends to every part of the country a power which has already proved so useful in urban communities. And now, to assist all Local Authorities, both Urban and Rural, in the framing of such bye-laws, and to ensure greater uniformity of treatment, we have to welcome the issue of this practical little publication, which may in truth be termed "The Plumbers' Code."

But though most Local Authorities will find the issue of these model regulations peculiarly timeous just now, when they are called upon for the first time to exercise their new powers of jurisdiction over the sanitary arrangements of buildings, it must be borne in mind that the publication is no hastily "got-up" one, in connection with the passing of the Public Health Act. On the contrary, it is a well-matured and most carefully considered body of rules, prepared by a committee of practical men as the result of four years of conscientious work. The committee was appointed in September, 1893, at a Congress in Aberdeen of Sanitary Authorities and others, in connection with the movement for the Education and National Registration of Plumbers. Its membership included Sanitary Inspectors, master plumbers, operative plumbers, architects, and others, from the six District Councils of Scotland—a membership which was thoroughly representative in character, and was a sufficient guarantee that the interests of no one class would be allowed to predominate, but that the one object aimed at should be the safeguarding of the public health. The bye-laws relating to drainage and plumbing work actually in force in all the chief centres of population were carefully prepared and digested, and everything that could be suggested by practical experience was added to the model rules. The product was finally submitted to the Eighth Annual Congress of Public Sanitary Authorities and Plumbers, held at Perth in September, 1897, and, after some further revision and adjustment, has now been published in its present form.

The history of the book and the auspices under which it has been published may well, therefore, lead us to regard it as authoritative, and as representing the latest and most up-to-date knowledge on the subject of which it treats. Nor after a careful perusal are our expectations disappointed. For the manner in which the work has been done we have nothing but praise. An introductory note briefly explains the statutory provisions under which the bye-laws must be framed. Then follows what we have called the Code itself, in sixty-three sections, dealing in detail with the drainage and every branch of plumber work, both of new and of existing buildings. Each section is accompanied by explanatory notes, in many cases of so thoroughly practical a character as to be of almost equal value with the rules themselves. The notes contain besides frequent references to the cognate sections of the Acts, as well as to the provisions of the bye-laws of the chief towns on which they are founded, thus enabling the reader to see at a glance how far these vary in different places. A set of twenty-seven carefully executed diagrams, illustrative of the regulations, concludes the book.

We should like, however, to modify the unstinted praise we have bestowed on the publication by one small word of criticism. It would have facilitated convenience of reference had there been marginal headings along with each section, similar to those in Acts of Parliament, briefly indicating the scope and contents of the section. This, we think, would have been a distinct advantage for purposes of reference; but beyond this trifling point we may be free with our commendation. The work has been done in a thorough and workmanlike manner. Every point connected with the drainage, the plumber work, and general sanitary arrangements of buildings has been minutely treated in the fullest light afforded by experience. Simple and unassuming in appearance, the book contains within its modest covers a store of practical knowledge, which, if thoroughly carried out, would go far to reduce disease in our midst. We have no hesita-

tion in saying that this useful little compendium will be found simply invaluable, if not, indeed, indispensable; not only to plumbers and Local Authorities, but to architects, engineers, Sanitary Inspectors, and, in short, to all connected with the building trade.

General News.

LEIGH.—The Council does not agree with the proposals made for a joint hospital, and intends to have a building of its own.

LANCASTER.—At the last meeting of the City Council the question of improving the sanitary condition of the town was discussed.

SANDBACH.—The Urban District Council has resolved to borrow £1000 for purposes of a water supply and a new road at Malkin's Bank.

LOWESTOFT.—Dr. T. St. Geo. Mivart has held a Local Government Board inquiry into an application to borrow £1400 for the extension of the sanatorium.

OSSETT.—The Local Government Board has forwarded the draft of a Provisional Order to amend the local Act of 1875 in regard to borrowing powers for waterworks and the investment of sinking funds.

LEITH.—The deaths registered within the burgh during the month of March numbered 137, being an increase of 41 on the preceding month, and an increase of 13 on the corresponding month last year, and showing a death-rate of 21·1 per 1000. There were three deaths from infectious diseases, viz., scarlet fever, one; erysipelas, one; measles, one. Under the Notification Act 91 cases of infectious diseases were notified.

REDCAR AND SALTBURN. — The Sanitary Authorities at Redcar and Saltburn have taken every possible precaution to guard against the introduction of small-pox, and up to the present their efforts in that direction have met with success. No cases of small-pox have been reported from either of the towns, and visitors who have been in the habit of spending their summer holidays at the pretty little seaside places have no reason to alter their plans.

BILSTON.—A Local Government Board inquiry was held recently into an application by the District Council for sanction to borrow £7000 for the purposes of water supply. Mr. Wassell, clerk to the Council, put in a statement showing that the total estimated cost of the waterworks was £53,750. This sum was 10 per cent. above the estimate, but the Council was perfectly satisfied with the expenditure. The loan now asked for was to cover the amount of the estimate.

LOWESTOFT.—The Corporation having decided to provide a refuse destructor for the borough, and fixed upon a spot known as Smith's Marsh for the erection, its proposals do not find favour with the inhabitants in the immediate neighbourhood, and a meeting was held recently to protest against Smith's Marsh being used for the purpose. It was agreed that a memorial be sent to the Town Council, and that the Council be asked to receive a deputation to support the prayer of the memorialists.

QUEENSBURY. — A Local Government Board inquiry has been held recently respecting the application of the District Council for permission to borrow £1500 to provide a water supply scheme for the mountain portion of the scheme.

BLACKWELL.—In consequence of the representations made by the Carlisle Rural District Council the Parliamentary Committee of the Town Council has recommended the Water Committee to extend the present water mains from Currock to Blackwell without delay.

Personal.

MR. W. WINDSOR has been appointed Inspector of Nuisances for the borough of Denbigh.

MR. J. R. HATFIELD has been appointed Medical Officer of the northern district of Forden union

Mr. J. E. HICKMAN has been appointed Medical Officer for the Coleford district of Frome union.

MR. W. J. PETCH has commenced duty as Surveyor to the Rawmarsh Urban District Council.

DR. WM. FAIRBANKS has been appointed Medical Officer of the workhouse of Wells union.

MR. H. BURTON has been appointed Medical Officer of Health for the urban district of Marple.

DR. J. W. SMITH has been appointed Medical Officer of Health for the urban district of Ryton.

DR. G. W. ROBERTS has been appointed Medical Officer of Health for the borough of Denbigh.

MR. G. R. COLLIN has been appointed Medical Officer for the Harrington district of Whitehaven union.

DR. JOSEPH FULLER has been appointed Medical Officer of Health for the Long Ashton rural district.

DR. S. G. NORRIS has been appointed Medical Officer for the western district of Llandilofawr union.

MR. F. G. SCOTT has been appointed Medical Officer for the Gillingham district of Medway union.

MR. JAMES WHITEHEAD has been reappointed Sanitary Inspector to the Rawmarsh Urban District Council.

Mr. J. B. HOLROYD has been appointed Inspector of Nuisances for the rural district of Hartsnene and Seals.

MR. J. B. HOLROYD has been appointed Inspector of Nuisances for the rural district of Ashby-de-la-Zouch.

DR. C. J. RENSHAW has been appointed Medical Officer of Health for the urban district of Ashton-upon-Mersey.

MR. GEORGE WILSON has been appointed Inspector of Nuisances for the urban district of Knaresborough.

MR. R. C. SPENCER, Horbury Wakefield, has been appointed surveyor to the Urban District Council at Belper.

MR. RIDDLER, of Stroud, has been elected surveyor and Inspector of Nuisances by the Urban District Council of Tewkesbury.

DR. BOND has been re-elected Medical Officer of Health for the rural district of Cirencester for the ensuing year.

MR. SAMUEL BROADHEAD has been appointed Inspector of Nuisances for the urban district of Milford Haven.

MR. A. D. FORBES has been appointed Medical Officer for the No. 7 district (Horsmonden) of Tonbridge union.

THOMAS PARTRIDGE, M.R.C.P., M.R.C.S., has been reappointed Medical Officer of Health for Stroud rural and Nailsworth urban districts, Gloucestershire.

MR. R. WEDGE, Sanitary Inspector of the Cannock Rural District Council, having resigned his position, Mr. H. M. Whitehead, surveyor to the Council, has been appointed to the position.

DR. SCARLYN WILSON has been appointed Medical Director and Consulting Medical Officer to the Borough Sanatorium, Hastings, at a salary of £300, rising by annual increments of £25 to £400.

IN consideration of Mr. Price, the Borough Engineer, Birmingham, resigning the office of Deputy Engineer to the Tame and Rea District Drainage Board the Public Works Committee recently recommended that his salary should be raised to £1000 a year. An amendment in favour of £800 found a good deal of support, and a vote disclosed the fact that the feeling of the Council was evenly balanced. The Lord Mayor gave his casting vote for the larger amount.

DR. JAMES PICHERN has been reappointed Medical Officer of Health to the Rawmarsh Urban District Council, although the Council refused to adopt his annual report in consequence of his having drawn their attention to the need of the (1) Adoption of Model Bye-laws (the present bye-laws were made in 1869, and not even in accord with the Public Health Act, 1895); (2) bye-laws under the Public Health Amendment Acts, 1890; (3) notification of infectious disease; (4) public slaughter-house. The Council has since adopted the Model Bye-laws.

Sewerage Schemes.

[TO MUNICIPAL ENGINEERS AND SURVEYORS.—The Editor will be pleased to receive items for publication relating to sewerage schemes projected or inaugurated, together with explanatory diagrams or photographs. The former should be drawn and lettered in black ink.]

PLANS are to be prepared and notices given for the drainage of St. Andrew's-road, Henley.

A SCHEME for the disposal of the Coventry sewage will be shortly laid before the Warwick Urban District Council.

AS to the important sewerage scheme which the Rotherham Corporation has in hand, necessitating an expenditure of £80,000 or £90,000, the Mayor recently announced that so far as the sanction of the Local Government Board was concerned the Council was getting nearer the end, and it was hoped that very shortly the work would be commenced.

THE Vestry of St. George-the-Martyr has decided to borrow £4250 from the London County Council for re-drainage works.

AT the last meeting of the Sculcoates Rural District Council it was decided that an independent expert should be engaged to report on the Hessle drainage.

IN his annual report Dr. Day, the Medical Officer of Health, says the drainage of Fordington (the Maumbury Way District) still requires attention, as the cesspools are frequently overflowing.

AT a recent meeting of the Keynsham Urban District Council a resolution was subsequently passed requesting sanction from the Local Government Board to borrow £14,000 for sewerage works.

AT a recent meeting of the Brierley Hill Urban District Council, the Sanitary Committee reported that Mr. Wilcox, the expert engaged, had presented his report on a joint scheme with Kingswinford for sewage disposal. The scheme will cost, it is estimated, over £20,000.

THE Local Government Board has sanctioned the borrowing by Hastings Corporation of several sums, including £110 for works of surface-water drainage (new surface-water drain, Bohemia-road); £303 for works of sewerage (new sewers—Halton-hill, £181, and Exmouth-place, £122).

AT a meeting held on the 31st ult., the Manchester Rivers Committee decided to recommend the City Council to carry out the bacteriological system in spite of the Local Government Board, and borrow the money without the sanction of that body under the Public Health Act. The estimated cost of the plan proposed is £127,000.

A NEW drainage scheme prepared by Mr. W. H. Radford, A.M.I.C.E., of Nottingham, has been considered by the Horbling Parish Council. This provides for a sewage farm, and the cost is estimated at £1300 exclusive of the site and maintenance, calculated at about £40 per annum. An alternative and less expensive scheme has been suggested.

A LOCAL Government inquiry has been held recently at Wood Green touching the application of the Urban District Council for the sanction of the Local Government Board to the borrowing of several sums, including £1549 for works of sewerage. With the exception of the suggestion of two or three very slight modifications, the Inspector appeared to be favourably disposed to the application.

THE Public Works Committee's report states that plans have been submitted for the laying out of various estates at Balsall Heath. The City Surveyor has prepared a scheme by means of which the whole of this area can be effectually and satisfactorily drained, the existing sewerage being insufficient. The proposed sewer will be an oval brick sewer, 3ft. 4in. by 2ft. 6in., and a 2ft. 3in. stoneware pipe, the estimated cost amounting to £5500. The Committee recommends that it be authorised to have the sewer constructed.

THE Gildersome Urban District Council has made application to the Local Government Board for sanction to borrow an amended loan of £2500, for purposes of sewerage and sewage filtration works.

AT Johannesburg, the proposition to have the existing temporary pail-and-cart system done by contract has fallen through on account of the tenders presented being much higher than the present departmental cost of the work. The introduction of the new sewerage scheme, on account of which Mr. C. Aburrow, the town engineer, made his recent visit to Europe, is waiting on the solution of the water supply difficulty, and when this has been achieved, the former important question will be actively taken in hand. Public meetings have recently been enforcing on the Authorities the need for despatch in the introduction of these works.

COLONEL A. C. SMITH, R.E., Inspector to the Local Government Board, held an inquiry on the 17th ult. into an application of the Farnworth District Council to borrow £22,160 for works of sewerage and sewage disposal, and £9600 for works of private street improvements. Mr. D. Crossley, Clerk to the Council, gave evidence as to the street improvements to be carried out, and Mr. W. J. Lomax, C.E., of the firm of Lomax and Lomax, of Bolton and Manchester, the Council's engineer, described the proposed works of sewerage and sewage disposal, stating that the Mersey and Irwell Joint Committee required the Council to improve their effluent, and in order to accomplish this it was intended to considerably alter the present precipitation tanks, to construct a range of six roughing filters with an area of 1800 square yards, and a similar range of polarite filters, also 1800 yards in extent, which will be intermittently and automatically aërated by Messrs. Lomax's system, which has been successfully applied at Astley Bridge, Failsworth, Denton, Bowness, and other towns. The purified effluent from the filter tanks would be passed on to land to meet the requirements of the Local Government Board, which Board, when the international system is adopted, only require that land shall be provided at the rate of one acre for every 2000 of population. The population to be dealt with at the proposed works is about 26,000. There was no opposition to the scheme.

Lighting.

A DISCUSSION took place recently at the Clerkenwell Vestry with respect to electric lighting, and it was eventually resolved to take the necessary steps to obtain powers.

THE tender of Mr. T. W. Thomas, of Hammersmith, amounting to £3504, has been accepted by the Vestry for work in connection with the extension of the electric lighting station.

THE Rotherham Town Council has confirmed the decision of the Gas Committee to make important extensions to the gas plant, which would involve an expenditure of about £15,000 to £20,000. The work will be carried out as occasion requires

THE Exeter Council has decided to apply to the Local Government Board for permission to borrow £7000 for additional plant and cables for electric lighting.

A PROVISIONAL Order has been received by the Ossett Town Council authorising it to lay down electric lighting plant and to supply electricity within the borough.

THE Salford Town Council has agreed to apply for leave to borrow for electric lighting purposes a sum of £33,000, instead of the £50,000 proposed in a resolution passed recently.

THE proposal of the Gainsborough Gas Company to promote a Bill to enable them to supply electric power has been discussed by the Urban District Council in Committee. A special Committee has been appointed to obtain advice and information.

AT a recent meeting of the Barking Urban District Council it was reported that the provisional contracts for the erection of the electric light station and for the supply and erection of generating plant had been entered into, and that the remainder of the contracts would be completed shortly.

AT a recent Newington Vestry meeting it was agreed that application should be made to the Local Government Board for its approval to the use of the land leased to the Vestry, between Penrose-street and the depôt premises, for the erection of an electric lighting generating station for the parish.

THE Stoke-on-Trent Corporation recently inaugurated at the gasworks a new gasometer, which has been built, at a cost of £7000, by Messrs. W. C. Holmes and Co., of Huddersfield. The new gasometer will hold 430,000ft. of gas, and meets a thirty hours' maximum demand. It is on the telescopic principle, with three lifts, and has a steel tank 25ft. deep by 90ft. in diameter, which will contain 1,000,000 gallons of water.

AT a recent meeting of the Wednesbury Council the Sanitary Committee recommended that application be made under the Electric Lighting Acts for a Provisional Order for supplying electricity for lighting and other purposes. The Mayor suggested that the Corporation make certain conditions with the Electrical Corporation to supply the town with electricity. After a protracted discussion the recommendation was carried by eight votes to five.

THE Leigh District Council has decided to apply to the Local Government Board for sanction to borrow £10,235. The Gas Lighting and Electric Lighting Committee recommended at its last meeting that the estimated cost of the proposed extensions and alterations at the gasworks be approved, and that the clerk be instructed to apply to the Local Government Board for sanction to borrow £25,000 for the purpose of carrying out such extensions. It was resolved that the plans and estimate be submitted to a gas engineering expert.

SEWAGE PURIFICATION.

(*To the Editor of* THE SANITARY RECORD.)

SIR,—I have just seen in your issue of March 25th a letter from Mr. Howatson suggesting the employment of heated air for the aëration of bacterial filters.

I do not quite know what his patent is, but I suggested this application of heated air in my paper contributed to the Institution of Civil Engineers in 1893.

I do not agree with him that the bacterial treatment is a violation of Nature's laws, as the greater part of the fertilising materials are present in the effluent from such filters in the form of soluble nitrates, which, if applied to the soil, provide the necessary nutriment for plant life in a form already prepared for its easy assimilation, while if the land is not in a condition to receive, or does not require the effluent, it could be turned into the stream without nuisance.—Yours faithfully,

SIDNEY R. LOWCOCK.

Birmingham, April 5th.

DISINFECTION OF ROOMS.

SIR,—It may be interesting to many of your readers in addition to myself, and of much importance to Sanitary Inspectors, to know which is the best means of disinfecting rooms after an infectious disease, say, for instance, scarlet fever.

Years ago we used Calvert's fumigator and carbolic acid 95 per cent., but the last few years we have been using sulphur 1 lb. to 1000 C.F.

An expert has now stated all that can be claimed for sulphur fumigation is the purification of the atmosphere, and that it does not destroy the germs that may be adhering to the walls, ceiling, &c.; therefore it has not our desired effect, and must be a mere farce. It would be a hard duty for a Sanitary Inspector to perform, if it lay in his power, to compel an owner of a house to remove the paper that had only been placed there a few weeks previously to the disorder appearing.

I should be pleased to know the legality of the subject, and also the views of those Inspectors who have practised different methods with success, as it is worse than useless to continue to use an article that is not capable of destroying the germs. I think if some moist material could be used it would prove more satisfactory than dry heat or fumes. I enclose my name and address.

SALUBRIOUS.

"SEWAGE DISPOSAL AND WHEAT GROWING."

SIR,—I am glad that your correspondent Mr. Bowler has inserted the thin end of the wedge—with your kind permission—*re* the enormous waste of national wealth at present going down our sewers by the water-carriage system now in vogue in the large towns of these islands. Your journal is ably conducted in the interest of sanitary science; but, inasmuch as every question has two sides, and an honest mean between the two sides, I sincerely hope you will open the pages of your paper to a discussion of both sides of the question, and that many of your very able correspondents will chime in with their quota of the views they entertain upon this very interesting subject.

A man may become a sanitarian from many motives, but no matter from what motive he becomes one, he must not close his eyes, nor steel his mind, against the questions of the day that surround him. The man who does so may be said to be on the high road to sanitary madness. It is because I wish to steer clear of any pitfalls that may be in the question, and that I wish to pursue an honest mean, that I address this letter to you.

I may set out by stating that I entertain the belief that midden privies have been, and can be again, so constructed as to render their contents quite innoccuous, and thus put an end to the squeamishness entertained by fastidious letter-writing and speech-making men and women of our own day against the chewed bread-and-beef contents of our much-abused midden privies. Now, the country is very good to the town—our supply of beef, bread, and milk comes therefrom; but how do we in the towns treat the country in return? I will now let Baron Liebig speak on this point: "The corn-growing agriculturist removes from a nectare (2½ acres) of his wheat field, in an average crop of corn of 2000 kilos., 70 lb. of the mineral constituents of the grain, of which 34 lb. consists of phosphoric acid, and 21 lb. of potash, and he supplies these to consumers in large towns. In an ox of 550 lb. weight the town receives 183 lb. of bones, containing nearly 120 lb. of phosphate of lime; in the flesh hide, and other parts of the animal 15 lb. of phosphates, which are identical with the constituents of the seeds of rye.

"The annual fluid and solid excrements of a million inhabitants of large cities (men, women, and children) weigh in the dry pulverulent state 45,000,000 lb., in which are contained 10,300,000 lb. of mineral substances, mostly ash constituents of bread and meat (not including 5,000,000 lb. weight of bones of the slaughtered cattle, &c., nor the mineral substances in the evacuation of horses, &c.). These human excrements alone contain 4,580,000 lb. of phosphates." (Page 218 of "Liebig's Letters on Modern Agriculture.")

So far, so good; but the evil does not end here. To-day, we stand face to face with a combination of powers arrayed against us. We have the fighting naval power to strike successfully, but the want of food at home paralyses our efforts in this direction; hence, the impotency of the efforts of our statesmen.

I am quite prepared to believe that the health of our urban population would not suffer any more than at present were our water-carriage systems—as far as w.c.'s are concerned—eliminated from our midst, and the produce of our privies again turned on the land once more. Certainly they would have to be differently and better constructed than they are at present.

Thanking you in anticipation.—Yours faithfully,

SANITARIAN.

THE London County Council has just opened another block of dwellings in the "Boundary-street area," Shoreditch. It is stated that every room has been taken, and that there were scores of disappointed applicants.

ANALYTICAL ANOMALIES.

CERTAIN alleged difficulties between the analyses of Dr. Frank L. Teed, analyst of the Islington Vestry, and those of the Somerset House officials, have recently been the subject of public comment. It is alleged that in the course of a fortnight three separate analyses of Dr. Teed's were proved to be inaccurate when the samples dealt with were referred to Somerset House.

Dr. Teed has been interviewed upon the subject at his laboratory in Victoria-street, Westminster.

"There are certainly three cases," said Dr. Teed, "in which my results differ from those obtained by Somerset House; but as to their having been 'proved to be inaccurate,' that is quite another matter.

"The first was a sample of lard, which I certified to consist entirely of fats other than lard. Somerset House found the sample genuine, and so did Mr. Otto Helmer, who analysed the sample for the defence. I exchanged samples with Mr. Helmer, and found his sample genuine, while he found mine adulterated. The sample analysed by me could not have been mixed with any other in my laboratory, as I had no other sample of lard there at the time.

"There is, therefore, a mystery about this case which is not easily explained. It may have been that only one end of the piece of lard was adulterated, and that in dividing it into three parts the adulterated end fell to my share. There are also other explanations, which one can hardly say anything about, whatever one may think.

"The second case was one of coffee. I found 90 per cent. of chicory, whereas Somerset House certified to only 52 per cent. I determined the percentage of chicory by Graham Stenhouse and Campbell's method, which was elaborated by them for the Inland Revenue department. Somerset House uses another method, for which they have been asked, a demand to which they have failed to reply.

"The third case presents very little difficulty. It was a sample of milk, in which I found 6 per cent. of added water. The Somerset House experts certified that they could find no evidence of the presence of added water, but they gave figures which showed on their own standard 2 per cent. of added water. I examined this milk when it was fresh; Somerset House only received it when it was highly decomposed, having, in fact, been drawn from the cow upwards of one month before they received it. Their results must, therefore, be looked upon as partaking of the nature of guesswork.

"Of course, it is unfortunate that three cases of this nature should occur one after the other. For the last ten years I have not had any of my results questioned by Somerset House. I am, however, very glad that a question is to be asked in the House, because it may help to compel Somerset House to publish the standards by which it works, instead of keeping them secret.

"I may add that in the milk case the Vestry is carrying it to the Queen's Bench, in order that the admissibility of the Somerset House certificates as evidence may be finally determined."

Notes and Queries.

Subscribers have the privilege of obtaining advice in this column on matters appertaining to Public Health Law and Municipal and Sanitary Engineering Letters should be addressed to THE EDITOR, "Notes and Queries," THE SANITARY RECORD, 5, Fetter-lane, London, E.C 1

NOTE.—If an answer be required immediately, a stamped addressed envelope must be enclosed, when we will endeavour to furnish a copy of the answer by post, as owing to the large number of queries received we cannot guarantee the insertion of a reply in the succeeding issue.

1034.—SANITARY INSTITUTE EXAMINATIONS: BOOKS FOR SAME.—"J. H. H." writes: "Do you publish any Guide to the Examinations of the Sanitary Institute, recommending books necessary for same? If not, what books do you recommend?"

Answer.—We do not know of any Guide-book to the Sanitary Institute Examinations. The following books may be recommended:—Reid's "Practical Sanitation," price 6s.; "Model Answers to Examination Questions for Sanitary Inspectors," price 2s.; Maxwell's "Calculations of Areas and Cubic Space," price 2s.; Maxwell's "Ventilation, Lighting, and Heating," price 2s.; Knight's "Diagramettes of Hygiene," price 1s.; Vacher's "Food Inspector's Handbook," price 2s. 6d.; Davies and Yabbicom's "Notes on the Factory and Workshops Acts," price 4d., and Taylor's "Sanitary Inspector's Handbook," price 5s. Any of the books named may be obtained from the Sanitary Publishing Company on receipt of the published price.

1035.—HOUSE DRAINAGE: DRAIN OR SEWER.—"F. J. A." writes:—"(1) Has the owner of property on plan enclosed the right to connect his house drain with the drain running down such road constructed by a private owner and connected with the main sewer? (2) Does the fact of two separate houses occupied by different persons, but owned by one person, make the drain in the private road a sewer; and, if so, does it not as such belong to the Urban District Council, irrespective of the person who constructed it? (3) Can my Council compel the owner of houses marked A to construct a separate drain in the private road to the main sewer, a distance of 80 yards; or can they only compel him to make a cesspool on his own land—that is, if he cannot agree with the adjoining owner to pass through his drain, or if it is not a sewer within the meaning of the Public Health Act, 1875, and the Public Health Act Amendment Act, 1890, which is adopted here?"

Answer.—(1) If the drain in the private road as at present constructed is used for the drainage of one house only, the owner of the houses proposed to be drained has not a right to connect his drain or drains thereto. If, however, the drain referred to receives the drainage of two or more houses, such a drain is a sewer, notwithstanding that it was constructed by a private owner; and the owner of the proposed new drainage may connect thereto without paying for the privilege. (2) Yes; such a drain is a sewer, vested in the Urban Authority. (3) The Council cannot compel the connection of a drain to a sewer when the latter is more than 100ft. from the site of the house to be drained. When no such means of drainage are within that distance, then the Local Authority may require the owner to construct a cesspool, into which the drains may empty—see Sec. 23 of the Public Health Act, 1875. The cleansing of the cesspool will devolve upon the occupiers, although the drain leading into it may receive the drainage of two or more houses.

1036.—THE PASTEUR-CHAMBERLAND FILTER: PARTICULARS.—"M. O. H." writes:—"Can you give me

any information about the Pasteur-Chamberland filter for purification of domestic water?"

Answer.—The Pasteur-Chamberland filter, the sole licensees and makers of which are Messrs. J. Defries and Sons, Ltd,, 147, Houndsditch, London, E.C., is the outcome of experiments made by M. Pasteur, who found that plates of plaster of Paris were effective in sterilising fluids in his laboratory work, and it afterwards occurred to M. Chamberland, his principal assistant, to apply the material used for the filtration of drinking water; hence the name given to the filter. The filtering medium now used is a specially-prepared fine-grained unglazed porcelain in the form of a cylinder, which is open at the lower end only, where it is provided with a glazed porcelain nozzle. The cylinder is enclosed in a case, through the bottom end of which the nozzle passes, and communicating with the top end there is a pipe with a screw socket for fastening the filter on to a water tap. The water enters the outer case, filters through the cylinder into its interior cavity, and escapes through the nozzle at the lower end. This is the form known as the tap filter, which works under pressure, but there are numerous other forms. As a result of two valuable sets of experiments to test the power of filters in removing micro-organisms from water, conducted, on the one hand, by Dr. H. H. Johnston, at the Public Health Laboratory of the University of Edinburgh, and, on the other hand, by Dr. Sims Woodhead and Dr. Wood for the *British Medical Journal*, it is stated that the experiments conclusively proved that the Pasteur-Chamberland filter is the best on which reliance can be placed for permanently sterilising drinking water. Our correspondent would probably find Dr. Rideal's "Water and its Purification," price 6s., a most useful book on the subject in which he is interested. The book may be obtained from the Sanitary Publishing Company, 5, Fetter-lane, London, E.C., on receipt of the published price.

1037.—Sale of Food and Drugs Acts: Appointment of Officer.—"X. Y. Z." writes:—"(1) Can an Urban District Council appoint their Inspector of Nuisances as an Inspector under the Sale of Food and Drugs Acts? (2) Is it necessary that such appointment be confirmed by the Local Government Board? (3) What manuals are the best to explain the duties and the legal powers possessed by such Inspectors? (4) Can an Inspector of Nuisances so appointed demand a salary for performing the duties of an Inspector under the Sale of Food and Drugs Acts?"

Answer.—(1) Yes. Where one-half of the salary of the Inspector of Nuisances is paid to the Urban Authority, under Sub-section 2 of Sec. 24 of the Local Government Act, 1888, the duties of the Inspector are prescribed by Article 9 of the Order of the Local Government Board, of March 23rd, 1891, and Sub-section 8 of this Order provides that the Inspector of Nuisances "shall, when and as directed by the Sanitary Authority, procure and submit samples of food, drink, or drugs suspected to be adulterated to be analysed by the analyst appointed under the Sale of Food and Drugs Acts, 1875, and upon receiving a certificate stating that the articles of food, drink, or drugs are adulterated, cause a complaint to be made, and take the other proceedings prescribed by that Act." It is also provided by Sec. 13 of the Public Health Act, 1875, that "any Medical Officer of Health, Inspector of Nuisances, or Inspector of Weights and Measures, or any Inspector of a Market, or any Police-constable under the direction and at the cost of the Local Authority appointing such officer, Inspector, or Constable, or charged with the execution of this Act, may procure any sample of food or drugs, and if he suspects the same to have been sold to him contrary to any provision of this Act, shall submit the same to be analysed by the analyst of the district or place for which he acts, or, if there be no such analyst, then acting for such place, to the analyst of another place," &c. (2) It will be seen from the above that by virtue of his appointment, an Inspector of Nuisances is also Inspector under the Sale of Food and Drugs Acts, and no additional appointment or confirmation is necessary. (3) Bell and Scrivener's "Sale of Food and Drugs Acts," price 4s. 6d., obtainable of the Sanitary Publishing Company, will be found an excellent manual for the use of Inspectors. (4) Inasmuch as it is a part of the duties for which he is appointed, an Inspector of Nuisances will not be able to require an additional salary.

1038.—Public Health (Scotland) Acts: County Sanitary Inspector: Powers.—"R. B. M." writes:—"What position does a Sanitary Inspector of a County legally occupy in connection with the introduction therein of (*a*) an adequate and suitable water supply for the population; and (*b*) as to the necessary works for the treatment of sewage? Will you please state whether the above duty is imposed by statute or bye-law?"

Answer.—(1) By the Local Government (Scotland) Act (1889), Sec. 52, power is given to the Council of every county to appoint and pay a Medical Officer or Medical Officers, and a Sanitary Inspector or Sanitary Inspectors, and also to effect arrangements for rendering the services of such officers regularly available in the district of the District Committee, on such terms as may be agreed, and the Medical Officer or Sanitary Inspector shall have, within such district, all the powers and duties of a Medical Officer or Sanitary Inspector appointed by a District Committee. And by Sec. 53 of the Act the Medical Officer and Sanitary Inspector are required to send copies of every report required to be made under the regulations of the Board of Supervision (which they are by this section authorised to make) to the County Council. The County Council are also empowered—where it appears to them that the Public Health Acts have not been properly put in force within any district, or that any other matter affecting the public health of the district requires to be remedied—to cause a representation to be made to the Board of Supervision on the matter. From the above it will be seen whence the County Council obtain their power to appoint Sanitary Inspectors, and also how they may exercise their powers of representation to the Board of Supervision against defaulting Authorities. The Board of Supervision framed Model Sets of Bye-laws, as authorised by Sec. 8 of the Public Health (Scotland) Act, 1867—now substituted by Sec. 15 of the Public Health (Scotland) Act, 1897, for regulating the duties of Sanitary Inspectors—which bye-laws are adopted, we believe, by most of the County Councils; and by Clause 1 of these bye-laws the Sanitary Inspector is required to keep himself informed by inspection of the sanitary condition of the county, particularly as regards drainage, water supply, and the existence of nuisances; and by Clauses 9 and 12 he is required to report to the County Council whenever it appears to him that the provisions of the Public Health Acts have not been properly put in force, and is also to prepare an annual report as to the condition and efficiency of all sanitary and drainage works, &c., within the county.

1039.—The Porter-Clark Process of Softening Water.—"L. J." writes:—"Would you please oblige me with the address of Mr. Porter Clark, the authority upon the process of softening hard water?"

Answer.—Our correspondent is advised to read up the different processes of softening water. There is no Mr. Porter Clark in existence, nor has been, whose name is connected with the process of softening water. The Porter Clark process is so named from the fact that a Mr. Porter, in 1876-7-8, took out patents for softening water which combined some improvements made by him on the well known process invented by Dr. Thomas Clark, of Aberdeen, who in 1841 had taken out a patent for

softening water by the addition of lime; hence the name or description—the Porter-Clark process—patented under this name. We recommend our correspondent to procure Dr. Rideal's "Water and its Purification," price 6s., obtainable from the Sanitary Publishing Company, wherein he will find the different processes of water softening described.

1040.—ORDERS OF LOCAL GOVERNMENT BOARD AND CANAL BOATS ACTS.—"J. F." writes:—"Will you please inform me what are the duties of an Inspector of Nuisances as laid down in the General Order of the Local Government Board issued to Urban and to Rural Sanitary Authorities, March, 1891? Also, what are the conditions under which a canal boat is required to be registered, and the objects of the Canal Boats Acts, 1877 and 1884?"

Answer.—We have not space at our disposal to detail the Orders of the Local Government Board nor to recite the provisions of the Canal Boats Acts. The information, however, will be found in Taylor's "Sanitary Inspectors' Handbook," price 5s., or Reid's "Practical Sanitation," price 6s., either of which books will be found most useful to our correspondent. The books may be obtained from the Sanitary Publishing Company, 5, Fetter-lane, London, E.C., post free, on receipt of the published price.

1041.—ACETYLENE GAS: APPLICABILITY FOR DISTRIBUTION.—"A. E. B." writes:—"A burgh of upwards of 2000 inhabitants have adopted the Gas Supply (Scotland) Act, 1876, and acquired works in a dilapidated condition from a company. Before proceeding with repairs, it has been suggested that the burgh could be probably as safely and more economically lighted by acetylene gas, distributed from one centre through the street mains in the same way as coal gas. The length of street mains would be about 7000 yards, and about 1000 lights would be required. Query:—(1) Do you know of any town about the size of above which is lighted throughout from one centre by acetylene gas? (2) Can acetylene gas be stored in the same way as coal gas? (3) Would it waste by evaporation in pipes during the daytime? (4) Is it more dangerous than coal gas in case of escape? (5) What are the Board of Trade regulations with regard to its use? (6) In your opinion, are the provisions of the Burgh Gas Supply (Scotland) Act applicable to rating and charging for acetylene gas in the same way as they are for coal gas?"

Answer.—(1) We do not know of any town lighted with acetylene gas. The manufacture of this form of gas is still in its experimental stage, and we doubt whether there is in the kingdom a gasworks forming a centre of supply for acetylene gas. (2) Hitherto, we believe, the gas-producing plants for acetylene are small and portable, the gas being generated only as fast as it is required for consumption. We do not know of any form of plant which provides for storage of acetylene gas. (3) We presume our correspondent requires to know whether the gas will condense, not evaporate. We have no means of ascertaining, but should assume that this will be the case. (4) Yes. (5) We are not aware. (6) The Burgh Gas Supply (Scotland) Act has not contemplated the use of gas other than coal gas, and we do not see how the provisions of Sec. 59 as to testing quality of gas can be made to apply to acetylene gas.

INSURANCE.

THE MUTUAL LIFE INSURANCE COMPANY OF NEW YORK.

PRESIDENT:
RICHARD A. McCURDY.

Policy-holders in the "Mutual" enjoy the advantages of

17 and 18, CORNHILL, LONDON, E.C.
D. C. HALDEMAN, General Manager.

CAMPHYLENE CREAM

(unlike most Fluid Disinfectants) possesses a most refreshing and agreeable odour, yet thoroughly effective.

Unequalled for use in Hotels, Clubs, Public Conveniences, for Flushing Drains, Sewers, &c. &c. Supplied to a large number of Corporations, County Councils, and other bodies throughout the United Kingdom. 3s. 6d. per Gall. in 5 or 10 Gallon drums. Samples and special quotations for quantities on application.

Fleming's Oil and Chemical Co., Ld.,
101, Leadenhall St., London, E.C

Contracts Open.

The dates given below are the latest up to which tenders can be received.

METHLEY (YORKS). — April 18th. — Sewers.—John Richardson, Esq., J.P., Methley Park, Leeds.

BLABY (LEICS).—April 18th.—Scavenging, &c.—Mr. B. A. Shires, clerk, Alliance-chambers, Municipal-square, Leicester.

KNOTTINGLEY (YORKS). — April 18th. — Sewerage Works.—Mr. John Richardson, M.I.C.E., engineer to the Council, 5, Central Bank-chambers, Leeds.

WIMBLDON.—April 18th.—Sewers, &c.—Mr. C. H. Cooper, engineer to the Council, Broadway, Wimbledon.

LONDON, S.W.—April 20th.—Sewer.—Mr. Charles Botterill, surveyor, Town Hall, Walham Green, S.W.

BIRMINGHAM. — April 21st. — Sewers. — Mr. John Price, city surveyor, Council House, Birmingham.

GREENOCK.—April 21st.—Sewers, &c.—The Master of Works' Office.

EDINBURGH.—April 23rd.—Electric Lighting.—Mr. R. Addison Smith, clerk and treasurer, 19, Heriot-row, Edinburgh.

HAWORTH (YORKS). — April 25th. — Scavenging. — The Council's Office, Mill Hey, Haworth.

WATERFORD. — April 25th. — Sewers. — Mr. M. J. Fleming, borough surveyor.

EGREMONT (CHESHIRE).—April 26th.—Sewers.—Mr. W. H. Travers, Public Offices, Church-street, Egremont, Cheshire.

STAPLEFORD AND SHARDLOW. — April 27th. — Sewerage Works.—Mr. W. H. Radford, C.E., Angel-row, Nottingham.

WINCHESTER. — April 30th. — Lighting. — The Surveyor's Office, Guildhall.

Vacancies.

ASSISTANT ENGINEER (LONDON, S.E., April 18th).—For the Vestry of Lambeth. Wages 35s. per week. Mr. Henry J. Smith, Lambeth Vestry Hall, Kennington-green.

ASSISTANT SURVEYOR (LONDON, W., May 2nd).—For the Vestry of Paddington. Salary £300 per annum, rising by annual increments for each year of approved service of £25 to £500 per annum. Surveyor's Department, Vestry Hall, Paddington.

BUILDING INSPECTOR (LITHERLAND, LANCS, April 16th).—For the Urban District Council. Salary £110 per annum. Messrs. North, Kirk, and Cornett, clerks to the Council, 15, Lord-street, Liverpool.

ENGINEER (SALISBURY).—Wages £1 5s. per week. Mr. Francis Holding, clerk, The Workhouse.

GASWORKS MANAGER (HUNGERFORD).—The Secretary, the Gasworks.

HIGHWAY SURVEYORS (DOCKING, NORFOLK, April 18th).—For the Rural District Council. Salary £80 per annum. Mr. J. A. Stoughton, clerk, Workhouse, Docking.

SEWAGE WORKS MANAGER (ATHERTON, LANCS., April 27th).—For the Leigh and Atherton Joint Sewerage Board. Mr. Daniel Scholfield, clerk, Atherton.

SURVEYOR, &C., (SOUTHWOLD, SUFFOLK, April 20th).—For the Corporation. Salary £60 per annum. Town Clerk, Town Clerk Office, Southwold.

To Surveyors, Sanitary Inspectors, &c.—First-class Cycles at reasonable prices. Don't place your orders elsewhere until you have seen our post-free catalogue.—MELROSE CYCLE COMPANY, Coventry.

COMPETITIONS.

CRICKLADE (WILTS), April 30th.—Water Supply Plans. —The Cricklade and Wootton Bassett Rural District Council invite engineers to forward a report, with plans and estimates, for furnishing an effective system of water supply to the town of Cricklade, Wilts, exclusive of the cost of the land or easements, but inclusive of all other expenses. Premiums of £21 and £10 10s. will be given for the plans which the Council shall adjudge to be first and second in order of merit. Mr. Harry Bevir, clerk, Union Offices, Wootton Bassett.

FORMBY (LANCS), July 1st.—Sewerage Scheme.—The Formby Parochial Committee invite competitive schemes for the sewerage of a portion of the township of Formby. Premiums are offered amounting to £100 for the scheme considered first in order of merit, £50 for the second, and £25 for the third. Mr. J. H. Havelock Sutton, Piercefield-road, Formby. A professional assessor will be appointed to adjudicate upon the plans.

Now Ready. Price 2s. net. Demy 8vo., 100 pp. Cloth, Gilt, Profusely Illustrated.

PART 1 OF NOTES ON

Practical Sanitary Science.

BY WILLIAM H. MAXWELL,

Author of Drainage Work and Sanitary Fittings, &c.

FORMING A COMPLETE TREATISE UPON

VENTILATING, LIGHTING, & HEATING.

PRESS OPINIONS.

"An entirely useful book, being both lucid and condensed, and the diagrams and illustrations are excellent. It is fully up to date, and well supplied with references, and as a text book is admirably suited to the needs of those for whom it is intended."—*The Hospital.*

"The book will not only be useful to candidates for examination, but also to busy men in practice who desire a summary of the chief points to be observed in carrying out any schemes of ventilation, lighting, and heating . . . the book is well illustrated and clearly printed."—*The Surveyor.*

Now Ready. Price 2s. net. Demy 8vo., Cloth, Gilt, 50 pp. With Numerous Diagrams.

Calculation of Areas, Cubic Space, etc.,

BEING PART II. OF

Notes on Practical Sanitary Science.

BY WILLIAM H. MAXWELL,

Author of Drainage Work & Sanitary Fittings, &c.,

PRESS OPINION.

"The 'Notes' will, we believe, be found to be of use also to engineers and surveyors in practice, being prepared in a concise form and of ready reference. Some of the most important theories as demonstrated in Euclid are given, and a passing reference is made to the use of Trigonometry and Logarithms. The concluding chapter treats of the calculation of quantities of earthwork."—*The Surveyor.*

ARTICLE No. 4.

ITS SUPERIORITY.

THE enormous sale of cocoa and chocolate both in this country and on the Continent indicates that, as a beverage, cocoa meets a public want. The large number of restaurants that have sprung up during the last few years, where non-intoxicating liquids, such as milk, tea, coffee, cocoa, chocolate, and aërated waters form the principal drink, and the success which has attended these enterprises, shows that there is a growing taste for beverages that "cheer but do not inebriate." The necessity of some stimulant to overcome the depression of spirits which is the natural consequence of the monotonous work, sedentary occupations, and impure air, which are the daily lot of millions in our large cities, arises, in the first place, from the fact that owing to the want of vigorous exercise a sufficient amount of oxygen is not taken into the lungs. The power of the heart to circulate the blood to the extremities depends in great measure upon the blood being properly aërated when it reaches the heart from the lungs. The heart beats more or less strongly in proportion to the amount of oxygen taken into the blood. When this aëration is unattainable, dulness of brain and inertness of body are the result, and some stimulant is instinctively sought to remedy the evil by stimulating the heart's action. Most of the beverages which are largely used throughout the tropical and sub-tropical regions of the globe, where the heat and moisture of the climate indispose to active exertion, contain, as an active principle, the body known as caffeine.

This is contained in coffee, tea, Paraguay tea, and Guarana and Kola nuts, all of which are used in different countries as a stimulant.

With the exception of Kola nuts, these all contain small quantities of substances which in some constitutions produce unpleasant effects. Thus tea may produce nervousness and symptoms resembling gastric catarrh; coffee may produce constipation; guarana acts as a purgative in those unaccustomed to its use; and Paraguay tea has a flavour to which Europeans do not easily get accustomed, and which in some persons produces nausea.

Kola nuts are not known to produce any disagreeable symptoms, but are lacking in aroma.

By mixing Kola with cocoa, therefore, the stimulant action of the caffeine they contain is communicated to cocoa without any corresponding drawback. Kola has the advantage, also, of containing about three times as much starch as cocoa, and when to this mixture malt is added, the starch is rendered soluble by a peculiar ferment called diastase, which occurs in malt, and thus the cocoa is rendered more nutritious.

The further addition of a carefully prepared extract of hops gives the well known sedative and tonic effect characteristic of the plant, and which is particularly useful in cases of weak digestion, in which tea would be apt to disagree.

Concerning Kola nuts, the Director of the Public Gardens and Plantations remarks in the Annual Report for 1883: "Kola nuts are said to have wrought very remarkable cures for dyspepsia and allied disorders, and are prepared for this purpose in the same manner as cocoa and chocolate. Some people use the Kola nut at breakfast regularly in this manner, and consider it superior to anything else of its kind."

Surgeon R. H. Firth, in the well-known medical journal, the *Practitioner*, states: "As an infusion, with milk and sugar, Kola powder is an efficient substitute for tea and coffee, being, especially for those affected with diarrhœa, superior to either. Its cultivation is likely to meet with success." And further, on p. 257: "These nuts are likely to take their place in the market as furnishing a nutrient and stimulant beverage. In addition to their nutritive and stimulant properties there is the probability that a chocolate prepared from them will more readily agree with delicate stomachs."

Professor E. Heckel, of the Institute Botanico-Geologique Coloniale de Marseilles, in an elaborate and exhaustive treatise on the Kola nut, entitled, "Les Kola Africaines," p. 290, gives the result obtained by Dr. Bertram in experiments made with Kola chocolate upon an entire battalion of soldiers, as follows: "(1) It is truly a food, and strengthens the vital forces; (2) it clearly has a stimulant property in exciting muscular action in men, which becomes evident in the fact that the charge and the walk of the soldier are more vigorously performed; (3) that the stimulant action lasts several hours, and that no depression follows its use."

Dr. Dujardin Beaumetz, a well-known physician in Paris, says (*Medical Bulletin*, October, 1884): "Naval surgeons have employed Kola with success in the chronic diarrhœa of hot climates, and its use is indicated in cardiac affections and cachexia. Good effects have been observed in these cases, in which it acted as an astringent tonic."

The *Pharmaceutical Record* (June, 1890, p. 226) states: "The German War Office, during the autumn manœuvres of last year (1889) has ordered thirty tons of the Kola nut for consumption in the place of coffee, tea, and cocoa. . . . It can be safely used by sufferers from indigestion and nervous or bilious headache. Statesmen, athletes, brain workers under tension of their powers, can use it advantageously."

The use of the Malt is so well known to the public, not only in the form of ale and beer, but in the preparation known to the public as Malt Extract, which is highly recommended and frequently prescribed by the medical profession, that it need only be said concerning its value as an addition to cocoa that malt contains a principle known as diastase, which renders soluble the starch present in both cocoa and Kola, and thus improves the nutritive qualities of the mixture. The advantage of hops as a tonic and sedative are familiar to all. Vi-Cocoa is, as its name implies, a cocoa to which tonic or strength-giving properties have been given by the addition of the articles here mentioned.

A little book, containing the reports of the very highest medical experts and analysts in the United Kingdom, showing the advantages of Dr. Tibbles' Vi Cocoa over all other food products, will be forwarded post free to any medical man (a post-card will do), along with a large sample tin.

Address—DR. TIBBLES' VI COCOA, LIMITED, 60, 61, and 62, Bunhill Row, London, E.C.

SITUATIONS.

VACANT.

☞ *Advertisements of Situations Vacant are inserted at the rate of Sixpence per line (prepaid), minimum three lines — eight words to line. Special rates for a series.*

WANTED.

THE SANITARY RECORD *will be found an excellent medium for those who are desirous of seeking Situations in the Offices of Surveyors, Sanitary Inspectors, Sanitary Engineers, Architects, &c. The charge for such advertisements (prepaid) is Sixpence per line. Minimum three lines—eight words to the line.*

☞ **Advertisements for this Department must reach us by Tuesday morning in each week, at latest.**

SANITARY INSTITUTE EXAMINATIONS.

TUITION BY CORRESPONDENCE.

An Engineer and Surveyor (Mem. San. Inst.), Certificated Surveyor and Inspector, prepares students for these Exams. by Correspondence through the post.

Fees strictly moderate. Cramming studiously avoided.

The course of tuition is arranged so as not only to qualify the student for passing the exams., but what is of equal importance, viz., that he may become a thoroughly efficient Inspector.

On successfully passing the exams., all possible assistance and advice is given to help forward intending candidates for public offices.

Many of my old pupils are now filling positions with salaries of over £120 a year.

For terms, &c., address "C. E.," care SANITARY RECORD, 5. Fetter-lane, London, E.C.

SANITARY ASSOCIATION OF SCOTLAND

EXAMINATIONS IN SANITARY SCIENCE.

Examinations for Certificates of Competency in Sanitary Science are held each year as follows, viz.:—In Glasgow in April, in Edinburgh in October, and at such other time and place as the Board of Examiners may determine.

Entrance Fee £2 2s.

For further particulars apply to

GEORGE MIDDLETON, M.A., LL.B.,
Writer, 92, Bath Street, Glasgow,
Secretary to the Board of Examiners.

A Stamped Addressed Envelope must accompany all letters requiring an answer.

SANITARY INSTITUTE EXAMINATIONS.

SPECIAL Corresponding Classes for the **Practical Sanitary Science,** and **Sanitary Inspectors' Examinations** of the **Sanitary Institute, 1898,** conducted by a gentleman holding appointments as Urban District Council Engineer and Sanitary Inspector, holder of three certificates from the Sanitary Institute, First-class Honour Medallist Hygiene, &c. Hundreds of successes.—For all particulars, testimonials, &c., apply Mem. San. Inst., Office of THE SANITARY RECORD, 5, Fetter-lane, London E.C.

OFFICIAL ADVERTISEMENTS.

THE SANITARY INSTITUTE.
EXAMINATIONS IN SANITARY KNOWLEDGE.

The next Examination in PRACTICAL SANITARY SCIENCE and for SANITARY INSPECTORS will be held in London on May 6th and 7th.

The last day for receiving applications for examination is April 23rd.

Forms of application and full particulars can be obtained at the office of the Institute, Margaret-street, London, W.

BOROUGH OF ROCHDALE.

The Health Committee are prepared to receive APPLICATIONS for the situation of ASSISTANT INSPECTOR of NUISANCES.

Wages to commence at 30s. per week.

No application will be considered unless the applicant holds a certificate of sanitary knowledge.

Sealed applications, stating age and qualifications, in applicant's own handwriting, with not more than three testimonials, addressed to me, and endorsed "Application for Inspector," must be sent in not later than April 19th.

The Committee do not bind themselves to appoint any one of the candidates.

J. LEACH,
Town Clerk.

Town Hall, Rochdale,
April 6th, 1898.

SECOND EDITION, Price 1s. post free.

CALCULATION OF CUBIC SPACE.

By C. H. CLARK.

NOW READY. Price 1s., by Post 1s. 1d.

SLOP WATER-CLOSETS.

By F. S. BUTTON, M. Inst. C.E., F.S.I.

Cr. 8vo. 16 pp. Price 6d.

Chemical Sanitation and Public Health

By WILLIAM BROWN.

A Paper read at the Glasgow Congress of the British Institute of Public Health.

HOUSE DRAINAGE DIAGRAMS.

By W. SPINKS, Assoc. M. Inst. C.E.

The Sheet, 31in. by 22in., embraces all details required by the Local Government Board Model Bye-laws.

Price 6d. nett, by post 6½d.

Special quotations for large numbers taken by Local Authorities direct.

THE SANITARY PUBLISHING COMPANY, LTD.,
5, Fetter Lane, London, E.C.

NOTICES.

ANNUAL SUBSCRIPTIONS. — The Annual Subscription to "The Sanitary Record," paid in advance, is 12s. 6d. This includes postage, and a Copy of the Diary, post free.

SUBSCRIBERS RESIDING in SCOTLAND and IRELAND are requested to pay by P.O. and NOT *by cheque. If cheques* BE *sent they must be drawn for 13s.*

MSS. cannot be returned unless accompanied by a stamped directed envelope.

Advertisements cannot be inserted unless received before Four o'clock on the TUESDAY of each week.

All communications should be addressed to the EDITOR, at 5, FETTER LANE, London, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, Ld.

THE

Sanitary Record,

APRIL 22, 1898.

CROWN PRIVILEGES.

The State exists for the people, *i.e.*, the nation, and it would be intolerable if the freedom of action of the administrative or executive departments of the Government should be at the mercy of factious, obstructive, or malicious individuals. It is expedient for the public safety that the Crown should have the power to appropriate inventions in explosives, in fire-arms, or other appliances of war, for a reasonable consideration, and there are officials, as the members of the diplomatic services of all countries, whose persons must be held sacred. But it is, on the other hand, nothing less than a scandal that all buildings, premises, and vessels being the property of, or even leased or hired by the Crown, not only for purposes of national defence, but for such as the accommodation of the local police or post-office business, should be exempt from the inspection or control of the Sanitary Authorities, without any guarantee being given that their condition shall not be a danger to the health of the employés, or even of the surrounding houses. Nay, more, there is nothing to prevent the officer in charge from concealing cases of infectious disease on the premises, and thus setting up a local epidemic. The mouths of the persons primarily aggrieved are closed, but from time to time unofficial and confidential complaints reach us as to nuisances which would not be tolerated on private property. It is not long since the person in charge of the post-office at 5, City-road was censured for having allowed the Sanitary Inspector to enter. The Vestry of St. Luke's served an intimation, followed by a statutory notice for the abatement of serious sanitary defects, but the Worship-street magistrate expressed, with regret, his inability to issue an order, and despite the exposure the Post-office authorities declined to act. Then for more than a dozen years the condition of the Central Telegraph Office has been disgraceful, and the only place where the operators can take any refreshment is a dark, dirty underground room, adjoining the w.c.'s and lavatories, which has acquired the name of "Cockroach Hall." Again, while the proprietors of places of public entertainment are often put to great expense in providing sufficient means of exit in case of fire, there is in the Central Office but one winding staircase, admitting not more than two men to pass abreast, along which at eight p.m. every day 900 pass out and 250 in at the same time. "Cæsar's wife should be above suspicion," and if the Medical Officer of Health and Sanitary Inspector must, on political grounds, be excluded, the control and sanitary supervision of all Crown property should at least be committed to some competent and independent officials, as the Medical and Engineering Inspectors of the Local Government Board. It is, however, but fair to add that despite the special exemption from notification of infectious disease in Sec. 55, sub. 7, of the London Public Health Act, a recent circular of the Local Government Board permits it as a matter of grace, not of right, though the interference of the Sanitary Authority in respect of "nuisances" is still prohibited.

Notes.

The Medical Officers' Society.

Among the numerous organisations of sanitary workers, that of the Incorporated Society of Medical Officers of Health occupies an important place. It has just brought its session for 1897—8 to a close, after a useful series of meetings, which have been recorded in these columns. Dr. Seaton, the well-known Medical Officer of Health to the Surrey County Council, will next

October vacate the presidential chair in favour of Dr. Edmund Gwynn, the equally well-known Medical Officer of Health for Hampstead. This Society, we are glad to notice—unlike many scientific bodies—is eminently practical, and at its gatherings and in its operations there is a pleasing absence of that professional jealousy which sometimes influences the professional mind. In view of the important position Medical Officers of Health occupy in the sanitary world, this is an evidence of the possession of a single eye to the public good, and it is therefore to be hoped that the Society will long flourish.

Medical Officers of Health and Meat Inspection.

A Medical Officer of Health is not enabled to refuse to inspect and examine meat believed to be unsound, except on payment of a fee, when asked to do so by the Inspector of Nuisances. Such is the opinion recently given by the Local Government Board to the Burnley Rural District Council, who sought their opinion in consequence of the Medical Officer of Health declining to examine a carcase of a cow, which the Inspector found had evidences of having suffered from tuberculosis. We do not see what other opinion could have been given, for the Orders of the Local Government Board regulating the duties of the Inspector of Nuisances and the Medical Officer of Health are, we should have thought, sufficiently clear to have rendered the matter, both to the Medical Officer and the Council, free from doubt. By Clause 7 of the Order as to the duties of an Inspector, it is provided that, "in case of doubt," before seizing any carcase apparently unsound, and intended for the food of man, the Inspector "shall report the matter to the Medical Officer of Health, with the view of obtaining his advice thereon." And by Clause 8 of the Order, relating to the duties of the Medical Officer, it is provided that "in any case in which it may appear to him to be necessary or advisable, &c., he shall himself inspect and examine any animal, carcase, &c. . . . And if he finds that such animal or article is diseased or unsound, or unfit for the food of man, he shall give such directions as may be necessary for causing the same to be dealt with by a justice," &c. Generally, we think, Medical Officers of Health are disposed to take a broad view of their duties, and are rightly imbued with a full sense of the responsibility of their office, which is to keep themselves informed, and to advise the Sanitary Authority on all matters affecting the health of the district. In such a matter as the one we have referred to, the responsibility of the Medical Officer is, or should be, greater than that of the Inspector; and we hope, and believe we are right in assuming, that such misinterpretations of his duties as is shown in this case are very rare.

The New Vaccination Bill.

The course adopted by the Government in their new Vaccination Bill, with regard to making vaccination compulsory, is evidently exciting a good deal of dissatisfaction in the country. Their disregard of the recommendation of the Royal Commission on the question of compulsion has aroused the bitterest anger of the uncompromising opponents of the vaccination law. Of course there are none so blind as those who will not see, and the opponents of the Government measure refuse to admit that the universal adoption of calf lymph will rob vaccination of its dangers. They plainly limit their belief and hope that if the Bill becomes law, it will be found to be unworkable, because either Boards of Guardians will decline to prosecute, or magistrates will refuse to convict. On this point, however, the Government must be firm. Difficulties may no doubt be expected in many places in enforcing the law, but when once the law is passed, after mature deliberation, it should be made perfectly clear that it *must* be observed.

The Extension of the Age Limit.

A Public Vaccinator, writing to the *Daily Chronicle*, states it as his opinion that the extension of the age limit for compulsory vaccination from three to twelve months will result in a large increase in the number of "unaccounted for" cases. The proportion of these cases which escape the vigilance of the vaccination officers is at present about one-fifth of the total number of children born in England and Wales; and it is contended that, if the compulsory age is extended to one year, this proportion is likely to be trebled. This argument, however, overlooks the fact that the extension of the age limit should very materially lessen the risks attendant on vaccination during the tender years of infancy, and should therefore tend to obviate the very natural fears of parents, which are at the bottom of all the opposition to the existing practice. And if a healthy public feeling grows up as to the wisdom of vaccination, and still more so as to its safety under a carefully administered law, the number of "unaccounted for" cases, instead of increasing, may rather be expected to diminish.

Result of the Battersea Vaccination Inquiry.

The Wandsworth and Clapham Board of Guardians have decided to terminate the engagement of Dr. Joseph, the Public Vaccinator, in consequence of the findings of the jury at the recent Battersea vaccination inquiry. It will be remembered that the inquiry related to the deaths of three children, which the jury found to be due to erysipelas, transmitted to them by vaccination; and the jury also added their opinion that Dr. Joseph, who vaccinated the children, had not exercised due care in the operation, and had omitted to observe some of the regulations prescribed by the Local Government Board. The case was a most unfortunate illustration of the dangers that attend the slightest carelessness in arm-to-arm vaccination, and offers a forcible argument in favour of the adoption of calf lymph, as proposed by the Government. Besides the three children who died, four others suffered severely; and the Board of Guardians have resolved on the very unusual step—subject to the sanction of the Local Government Board—of awarding £7 each to the parents of the deceased children, and £5 to the parents of the others, by way of compensation.

Our English Prison System.

One of the last measures of the session brought forward by the Government was the Home Secretary's Prisons Bill, which, in spite of the violent attacks directed against it,

chiefly from the Irish benches, was read a second time without a division. The subject of our prison system is one regarding which a good deal of popular ignorance prevails. One hears the opinion frequently expressed that the conditions of prison life now-a-days—unlike what they used to be in a former generation—are such that the average criminal is much better housed, and fed, and clad, than when he is at liberty. Indeed, from the sanitary point of view, he is supposed to have no reason to complain, and the healthiness of our prison *régime* is often rather indiscriminately applauded. To a certain extent this view is perhaps correct; that is, at least, in regard to the ordinary criminal population, whose sanitary standard is necessarily a low one, as they belong to the lowest stratum of society. But the defects of our prison system, though not so bad as they once were, are still sufficiently glaring. There is considerable difference of opinion as to the lines on which reform should proceed, but the necessity of reform of some kind or another is admitted on all hands by those who have any acquaintance with the subject.

The Government Measure.

The present Bill is the outcome of the report of a Departmental Committee appointed by Mr. Asquith, and presided over by Mr. Herbert Gladstone. Some of the reforms recommended by that Committee have already been adopted by the Home Secretary; for others legislative sanction is required, and they are dealt with in Sir Matthew White Ridley's Bill. So far as these are related to the principles which underlie our corrective system—principles which really form part of the great social question—they fall beyond the province of this journal to discuss. Such are those which treat of the differential treatment of prisoners, the shortening of sentences by good conduct, corporeal punishment, &c. But there are other aspects of the measure in which we are vitally interested; for instance, the sufficiency and the quality of the prison diet, the warmth and cleanliness of prisoners' clothing, the question of solitary confinement, the character of the work assigned to prisoners, their opportunities for exercise, and the facilities for non-official visitation. Space forbids us, however, to discuss all these questions here at length. We can only refer shortly to one or two points that were prominently noticed in the debate in the House of Commons.

Sanitary Aspects of the Question: The Prison Dietary.

Some of the charges against the present system brought forward by Irish members (some of whom are, of course, tender on the subject) were obviously reckless and wild. Such, for example, may we consider Mr. T. P. O'Connor's declaration that it was "a system of deliberate, calculated, cruel, scientific starvation;" as also his further charge that sleeplessness was developed by the plank bed into a chronic disease. The Home Secretary had no difficulty in disposing of the first of these points, as there was no trace of it to be found either in the complaints of prisoners, or in the reports of the Royal Commission, or the Departmental Committee. It was absurd, he said, to speak of "scientific starvation," when it was ascertained that out of 180 prisoners discharged from convict prisons last year, no fewer than 97 had gained in weight on an average 7 lb. At the same time Sir Matthew Ridley was quite prepared to admit that there was some room for improvement in the prison diet, though the actual state of matters had been very much exaggerated. It was suggested that there might at least be some inquiry into the subject, if only to satisfy the public conscience.

Overcrowding Juvenile Prisoners, etc.

Mr. Asquith touched on a more substantial grievance when he spoke of the overcrowding of prisons, which was partly due to the excessive length of some of the sentences, and partly to the reluctance of magistrates to grant bail to prisoners on remand. This state of things, however, will largely be remedied by one of the clauses in the Bill. So, too, with regard to juvenile offenders, who should, if possible, be segregated. On both of these points Sir Matthew expressed himself as in entire accord with Mr. Asquith, adding that a good deal was already being done in this direction by the Department without legislation. The Home Secretary further indicated his desire to have prisoners employed in the open air, in such occupations as agriculture and gardening, though that is not always easy in the great centres of population. The aim of the Department, in short, is to humanise and ameliorate the conditions of prison life as far as possible. Great and sweeping changes in prison administration have been introduced in recent years, so that the charges which might not long since have been made against the system are no longer true; but the system is still full of defects which can be removed, and the object of the present Bill is to amend and consolidate the whole prison code, in the direction of establishing a more humane and healthy *régime*.

The Plague in India.

It is satisfactory to hear that the mortality from the plague in Bombay is steadily decreasing. Reuter's latest telegrams are exceedingly meagre in their information; no figures are given; but the broad statement is certainly reassuring. The immediate result of the improvement in the health of the city is a healthier tone in business. There are general indications of a revival of commercial activity. The receipts for the present month, as indicated in the returns of the Port Trust, show a marked increase as compared with April of last year, denoting a return to the normal conditions of trade. The receipts of railways connected with Bombay have also latterly shown a steady increase. We should like, however, to see fuller information about the death-rate.

TO OUR READERS.

The Editor solicits the co-operation of readers in making The Sanitary Record *more attractive by means of pen-and-ink sketches, photographs, and diagrams. There are many phases of sanitary work which lend themselves admirably to illustration. By this means not only individual articles, but the journal as a whole will be brightened.*

NOTES ON
PRACTICAL SANITARY SCIENCE.

By WILLIAM H. MAXWELL.

Assistant Engineer and Surveyor, Leyton Urban District Council, Author of "Drainage Work and Sanitary Fittings," "Ventilation Heating, and Lighting," &c., Certificates of the Association of Municipal and County Engineers, and Sanitary Institute.

No. 57.—REFUSE DESTRUCTORS.

(*Continued from page* 363.)

Mason's Refuse Gasifier.

Mason's patent continuous refuse gasifier is an apparatus of an entirely novel character for dealing with refuse. It is illustrated in section by the accompanying figure 28, and the following details of the system will be of interest:—

In this furnace, instead of burning the gases as they are distilled from the refuse, they are carried into a combustion chamber. Here they are mixed with the necessary amount of heated air to create combustion, with the result that a very high temperature is obtained which can be utilised for raising steam. It is claimed that "1 lb. of water can be evaporated for every pound of good refuse," and the heat obtained is about 1500 deg. Fah. The combustion of the gases being perfect, the nuisance of smoke, smell, dust, and partially burnt paper is obviated, as well as the cost of a fume cremator.

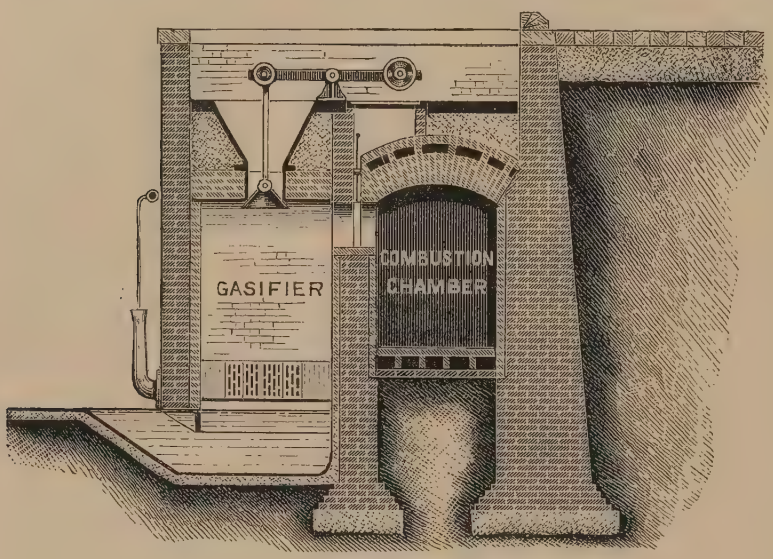

Fig. 28.—Mason's Refuse Gasifier.

The cells can be built either rectangular or cylindrical. At the base is a water trough, which covers the whole area of the cell, and into which the residue of the consumed refuse falls, from whence it is removed by means of a rake. The water trough also acts as a seal to prevent any gases escaping, and the vapour arising therefrom, together with the steam jet, prevents the grate bars from clinkering up. In the centre of the cell, immediately above the water trough, the grate bars are fixed in a sloping position. Near the top of the cell, on any side most convenient, there is an outlet for conveying the gases into the combustion chamber, and from thence into the flue of the chimney.

The total grate area is 12 square feet, and the manufacturers guarantee to destroy from 5 tons to 8 tons per cell per twenty-four hours.

The refuse is fed into the gasifier by means of a hopper at the top. It falls on to the grate already described, and, after combustion, slides into the water trough below, where it is cooled, ready for taking away. Steam and air are forced under the grate bars to create a draught, so that the cost of a high chimney is, it is claimed, thereby dispensed with. Where it is not intended to utilise the heat generated for steam raising, a small boiler will be necessary to supply steam for forcing the draught. No fuel of any kind is required, except when first lighting a cell. At the week-ends the cells can be banked up with refuse, and started again on Monday morning by merely turning on the steam.

The refuse is reduced to about 25 per cent. of its original bulk, varying, however, according to the percentage of combustible matter contained in it. The slow combustion that is taking place during the distillation of the gases from the refuse reduces the residue to ashes of a a suitable character for grinding for mortar making or for use as ballast for roads and footpaths.

As regards the labour required, the constructors state that two men are able to charge six cells and attend to the proper working of them. The total cost of construction, including royalty, may be taken roughly at £200 per cell; this is exclusive of any other work outside the cells proper. Owing to the comparatively low temperature at which the cells are worked, the cost of repairs is said to be small. This system is in use in the district of the Moss Side Urban District Council, near Manchester, where it may be observed that there is no smoke or smell emitted, although the chimney is only 25ft. high. The refuse consists of ashpit refuse, fish offal, and slaughter-house residue.

The patentees and constructors of this Refuse Gasifier are Messrs. W. F. Mason, Limited, engineers, Longsight, Manchester.

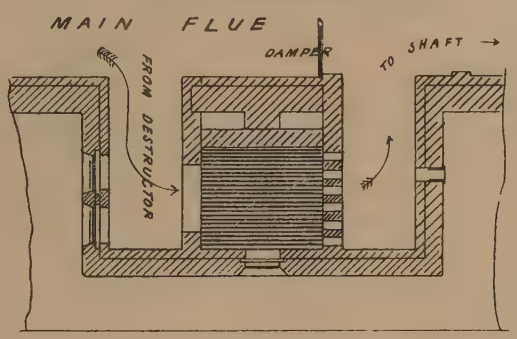
DESTRUCTOR ACCESSORIES.

Jones' Patent Fume Cremator.—This contrivance has been the refuge of many of the earlier destructors, which, being incapable of "consuming their own smoke," have stood seriously in need of some such remedy, inasmuch as public nuisances and legal difficulties have arisen almost simultaneously with their erection. Hence it is that we find the "cremator" forming an essential part of a large proportion of the older destructor installations at the present time.

Not long after the erection of the first destructor in the vicinity of the metropolis, viz., that at Ealing in 1883, complaints of nuisance arose. The vapours given off in the drying of the refuse whilst undergoing its first stage of burning, were very perceptible, and formed cause for complaint; as also did the escape of fine dust, &c., from the chimney shaft. The fact of the existence of a nuisance, it was found, could not be ignored; and, after some consideration, it was concluded that the nature of the furnace was such that the difficulty was only to be overcome by the construction of an *absolutely independent furnace*. This difficulty gave birth to the "fume cremator" in 1885. It was designed by Mr. C. Jones, M.I.C.E., Engineer and Surveyor to the Ealing District Council, who patented the arrangement for the purpose of cremating and rendering harmless the objectionable fumes, known as the empyreumatic vapours, which arise during the earlier stages of the process of burning towns' refuse.

The accompanying figures 29 and 30 show the construction of the furnace, and it will therefore be

Fig. 29.—Plan of Jones' Fume Cremator.



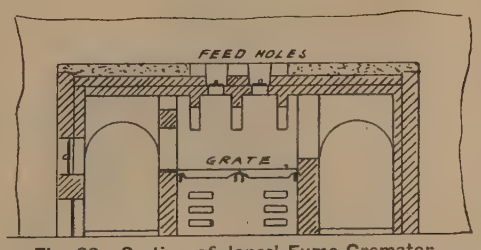


Fig. 30.—Section of Jones' Fume Cremator.

unnecessary to give a detailed verbal description. Briefly, the "cremator" consists of a reverberatory arch, with rings of fire-brick placed in the direction of the gases. Ribs of fire-bricks projecting from the arch serve to deflect the gases, and direct them on to the top of a red-hot mass of fire. A heat, varying from 1000 deg. to 1500 deg. Fah., is maintained at a small expense of fuel, fine coke-breeze alone, or with the ashes screened from the refuse, being all that is required, together with a supply of air beneath the fire-bars, and a further supply to feed the vapours as they pass into the cremator.[139]

The furnace has from time to time been very favourably reported on by many of those having experience in its use, and also by scientific experts employed to examine as to its utility, but any such appliance obviously betrays the destructor to which it is attached.

The fuel used in the cremator is either coke breeze, coke breeze and screened ashes, screened ashes alone, or small coke. The cost of cremating the fumes per ton of refuse destroyed varies from ¼d. per ton, where only cinders are used, to 3¼d. per ton. At Batley, where coke is used, the cost is given at 7d. per ton, and at Nelson, where the destructor was of the "Beehive" type, 3s.

In the discussion which followed the reading of a paper at the Sanitary Institute on "House Dust Refuse," by Mr. J. Russell, in February, 1892, it was stated that with regard to the destructor at Hornsey a *fume cremator* had been added to it, but that it had not been found necessary to use it so long as the firing of the furnace was carefully attended to. The chimney of the destructor was 217ft. high. The cost of using the *cremator* came to about £800 a year,[140] as it was found necessary to use coke for firing. The use of coke breeze had been tried, but caused large volumes of smoke.

Speaking generally of cremators, the following observations[141] of Dr. Stevenson Macadam, Ph.D., F.I.C, &c., appear to be very much to the point. He says: "The difficulties connected with destructors in general for the thorough combustion of the refuse and the escaping gases into innocuous matters, arise mainly from the varying conditions of any single cell from time to time, so that, even when it is possible to get up the proper temperature when the cell is in full blast and in the cindering and clinkering stage, yet, when the charging operations are proceeding, and for some little time thereafter, the temperature becomes lowered below what is required for efficient treatment of the refuse and its products. To overcome the deficiencies, recourse has been had to the use of *cremators*, which practically form part of the main flue, and where a bed of red-hot coke or other fuel is supposed to be constantly burning, and over which the smelling gases must pass and ought to be consumed. The suggestion and construction of these cremators is an admission of the inefficiency of the destructor proper, and are *a mere whitewashing of an imperfect machine*.

"The cremators are costly in working, are not properly attended to, and though I have repeatedly looked at them during my inspection of the destructors, and have even been told beforehand that they were in operation, I have never yet found one of them in actual full work, though otherwise they were in serviceable condition.

"A *cremator* should not be called upon to check or rectify the imperfections of any destructor, and the destructor proper should be capable of doing its own work."

The "Carboniser." — The "Carboniser" was invented by Mr. Fryer for the purpose of converting vegetable refuse into charcoal, but it has not proved a success. It was erected at Leeds, Birmingham, Warrington, and Derby; at which last-named town alone is the furnace still in use, and there only to a very limited extent.

Mr. Codrington gives the following description of the carboniser at Derby:—

It consists of a group of four cells of brickwork,

139 Mr. C. Jones' "Refuse Destructors" (1894).

140 "Transactions" of the Sanitary Institute, vol. xiii., page 57

141 *Journal* of the Society of Chemical Industry, 31st March 1896.

each 2ft. by 3ft. 6in., and 13ft. high, with a vertical flue in the middle, and a furnace alongside each cell at the bottom. Within the cells a series of cast iron plates are fixed with their upper edges touching the walls, and their lower edges standing away, forming a continuous sloping ledge winding round the cell from the top to near the bottom, where they terminate in a fire-brick chamber having a sliding door in the bottom.

The refuse is fed in at the top, and is not mobile enough to rise behind the plates, so that a spiral flue is left for the passage of the hot gases from the furnace at the bottom to an opening into the vertical flue at the top and downwards to the chimney.

The refuse dries and sinks coming into contact with hotter plates as it descends until it reaches the red-hot fire-brick chamber. *No air reaches the refuse except through the furnace, and it is therefore charred and not burned.*

At intervals the sliding door in the bottom is opened, and a charge of charcoal is withdrawn. Each cell carbonises about two tons of refuse in twenty-four hours. The furnace burns cinders selected from the ashpit contents. The charcoal is cooled in a revolving cylinder on which a stream of water flows, and is sifted through a screen at the end in a fine powder.

At Derby the carboniser cost £1000; it was worked about two days a week at a cost of £18 per year, and produced about 20 tons of charcoal a year, a ton of vegetable refuse, sawdust, &c., yielding a hundredweight of charcoal, which was used for deodorising, and valued at £5 per ton. This apparatus is now being pulled down for space to erect more destructor cells.

At Leeds no use or market was found for the charcoal, and analysis proved it to contain 80 per cent of earth.

Furnace for recovery of tin and solder from old cans.—A small furnace for the recovery of tin and solder from old cans has been introduced by Messrs. Manlove, Alliott, & Co., Limited, The solder tins are collected in hampers or other handy receptacles and tipped directly into the oven. In the course of three or four minutes the solder will be seen running out in a stream through the small aperture and shoot, which lead it into the collecting receiver. When the attendant is satisfied that the whole of the solder has been recovered or run down into the receiver, he moves a handle, which causes the tins to fall on to the lower set of bars, where they are raised to a red heat, and the tin completely burnt off.

The whole process as a rule occupies little more than an hour, and it is found in practice that it may be repeated eight times per day. The fuel is placed on a set of fire-bars near the bottom of the oven, and usually consists of refuse material, such as waste paper, cardboard, hampers, &c., which comes in with the ordinary house and town refuse.

The furnace performs two operations: one, the melting off and collecting of the solder, and the other burning the tin off the iron so as to leave "scrap" of a marketable character. Both processes are carried on at the same time. The economical value of the invention may be gathered from the fact that the solder may be disposed of at prices varying from 5d. to 8d. per pound, and is usually about two-thirds the market value of tin.

THE SANITATION OF DOMESTIC BUILDINGS.

By Frank Latham, C.E., M. San. Inst., &c., Assistant Surveyor, Borough of Margate.

CHAPTER VI.

Section 5.

BATHS AND LAVATORY BASINS.

An essential and important factor in assuring and maintaining good health is personal cleanliness, which to every individual should be a habit of life. The neglect of the natural law by which the waste substances of the body are removed through the

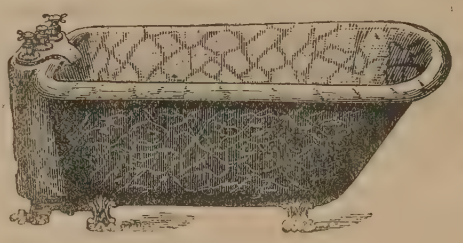

Fig. 81.

pores of the skin is that the perspiration instead of being freely removed is unduly thrown back on to the lungs and other organs, the result being that the system is lowered and rendered more liable to disease. It is therefore highly desirable that facilities for frequent ablutions should be provided in the dwelling-house. The excuse of want of room is hardly sufficient for its absence. The writer has seen in houses where the space has been exceedingly limited, baths conveniently fitted and

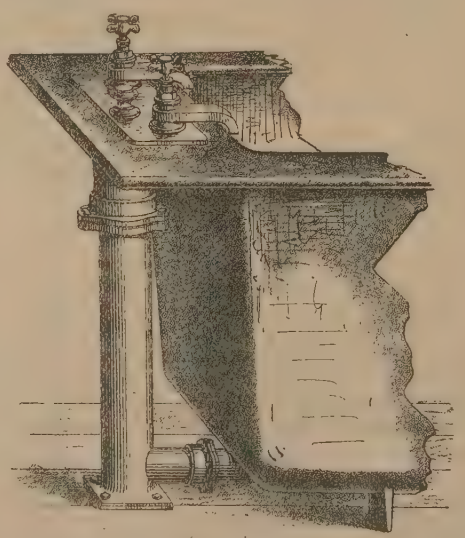

Fig. 82.

framed with a mattress on the cover, thus serving a double duty as bed and bath.

The variety of baths now on the market are too numerous for their merits or demerits to be enlarged upon in the present article, but the following brief descriptions will give a fairly general idea of them. Cast iron baths enamelled internally with roll edges and ornamental feet are simple in

construction and of good appearance (Fig. 81). These baths do not require framing in. Some persons prefer a wooden to the roll iron edge as not striking so cold. These baths can be obtained with flanges arranged for an edging of woodwork being fitted to them. Copper baths are to be recommended in preference to iron, where they are much used, such as in hotels, schools, &c., as the latter under such circumstances, owing to the expansion and contraction, are liable to crack and become useless.

Some of the most cleanly baths manufactured, and particularly suitable for hospitals and public baths, &c., are constructed of thick earthenware glazed inside and outside, thus needing no framing in. This description of bath has a very inviting look in hot weather, whilst in the winter, when once warmed retains heat for a considerable time. Wood-framed and lead-lined baths are now obsolete. Zinc baths are cheap, but not to be recommended.

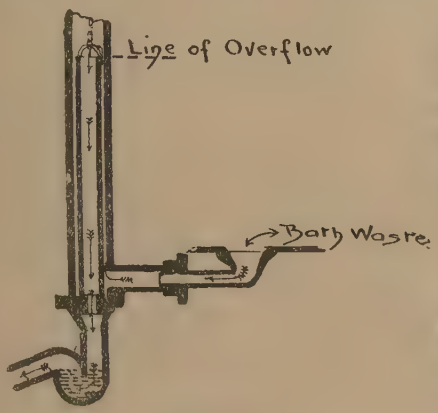

Fig. 83.

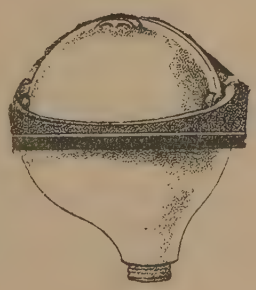

Fig. 84.

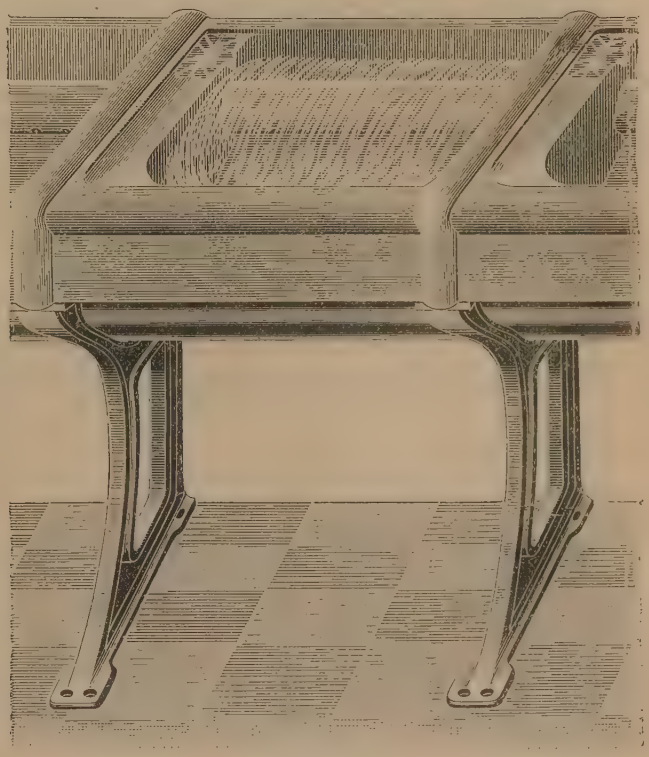

Fig. 85.

All baths should be fixed against an external wall, and, as mentioned in Chapter IV. respecting sinks, the waste pipe should be properly trapped immediately beneath the apparatus, the pipe being arranged to discharge in the open air, either over a gully channel or connected with a special bath waste pipe carried up with an open end as a ventilator, and discharging under a gully trap grating at the foot. Overflow pipes should always be fixed and connected to the bath waste pipe at the house side of the trap (Figs. 82 and 83).

When there is more than one connection a ventilation pipe must be carried off the waste pipes to prevent syphonage, such ventilator to be terminated in the open air a short distance up the wall. The baths should also be provided with lead safes somewhat wider than the baths, with the usual waste pipe, its end being covered with a proper flap valve. The waste pipes from lavatory basins, also, should be treated in precisely a similar manner as those of baths.

Some of the forms of lavatory basins are as follows:—The plug basin is simply a glazed earthenware basin fitted with a plug and chain, having also provision at the side to prevent overflow; these basins being inexpensive and lasting, are extensively used. The flushing rim basin is similar to the above as regards the plug, &c., but, in addition, is supplied with water through a flushing rim, so that the whole surface of the basin is well cleansed each time the water is turned on. The tip-up basins for lavatories are oval in shape, suspended in receivers (Fig. 84). They are clean and simple in action, being especially adapted for clubs, hotels, and public lavatories. Twyford's "Rivulet" lavatory basins (Fig. 85) are supplied with a continuous flow of water, and designed for use in schools to obviate the possibility of a number of children washing in the same water, dirty water being carried away over a weir at the back of the basin into a waste pipe, whilst all sediment is removed into the same pipe through an outlet in the bottom of the basin.

Lavatory basins should be fitted in a slate or marble top, supported by iron brackets or standards, such top having a small bead at the edges to prevent splash water from running over on to the floor.

(To be continued.)

"PRACTICAL SMOKE PREVENTION."

By W. Nicholson, Smoke Inspector, Sheffield.

(*Continued from page* 392.)

Insufficiency of boiler power.—This is another cause of black smoke. Many people are very sceptical on this subject, and say they don't believe that manufacturers would put down a boiler too small for the work they desire to do; they would consult an engineer, and know exactly the size of boiler required, and put such a one in. Yes, that is perfectly true, they do; but seldom in their calculations do they consider the development of their business, the probable additional power required, and order the boiler accordingly. No, they order for the present, and afterwards keep adding machine after machine, until they find the boiler is too small for the work they desire to do. Many manufacturers are so situated. Many difficulties confront them when called upon by the Press or Public Authority to provide more boiler room; it is much easier said than done. (1) The cost, say, at least £300, which means a great outlay to small struggling tradesmen; (2) shortness of room; and (3) their trade is such they cannot afford to lose the time necessary for the alterations without largely losing their trade, which would mean ruin to many of them. It is necessary when talking about providing more boiler room to consider the difficulties manufacturers have to deal with, and treat them accordingly. We cannot lose sight of the fact that shortness of boiler room is another of the great causes of black smoke. We may ask ourselves, In what way? (1) The fires have to be unduly forced in order to generate steam quickly enough to meet their requirements, the fireman is constantly throwing on green coal, and knocking his fires about to try and get from the boiler more than its maximum power. With what result? Extra labour for the fireman, coal wasted, and dense volumes of black smoke emitted. The only remedy when under such conditions is a bigger boiler. It is only fair to state (and it has been proved many times) that with careful firing, which means firing lightly and often, much smoke can be prevented, and the maximum power got from the boiler, but some of the firemen when pushed for steam, by the shouting of the men in the forge or mill, at once lose their heads, begin to knock their fires about, mixing the clinkers amongst the coal, and thus generating less steam than they otherwise would do if they fired with care in the ordinary way.

By briefly looking at the above five things, which are mainly or wholly the cause of producing black smoke, we cannot help but be convinced of the enormity of the cost. (1) Financial, waste of coal; (2) public health—disease caused by dirt; and (3) the moral cost, which is often forgotten. Many of the poorer people are compelled to live in districts where they are at times almost enveloped in smoke. The dirt they cannot dispose of; hence in time, being surrounded and living in it they become dirty in habit, dirty in morals, and debased to an incalculable degree, and in the end public morals are affected as a consequence. Having pointed out the cause of black smoke, we are now confronted with the question,

CAN IT BE CURED OR PREVENTED?

To such a question we say "Yes" at once. A manufacturer was prosecuted for emitting black smoke. Evidence was given, and the nuisance proved to the satisfaction of the Court. The stipendiary asked the defendant if he could abate the nuisance in one month, if he made an order to that effect. The defendant said in reply, "he could completely abate it in fourteen days and would do so." This answer somewhat surprised the stipendiary, who asked how he would do it. The defendant, replying, said, "he should go back to the works, give all the men notice, set down the furnaces, and shut up the shop, then there would be no nuisance to complain about." That was one way to prevent a nuisance, but not a very practical way, because the cure in many ways would be worse than the disease. Some may think by the citing of the above instance that nothing ought to be done to compel manufacturers to take practical steps to prevent black smoke nuisances. Nothing of the kind; I am only pointing out how much easier it is to prevent smoke than to practically consume it. There are those who say that very little has been done in the past—say, twenty years—to put an end to this intolerable smoke nuisance; to such I would say (with all kindness) that they know nothing at all about the question. If they were manufacturers they would sing a different song, especially if they were situated in Sheffield. They no doubt base their conclusion on the number of prosecutions taken. If so, they have not the slightest conception of what has been spent in every kind of so-called smoke consumer. I could give scores of cases where hundreds of pounds have been spent on appliances, simply through the service of a notice to abate. Let me state one. A chimney emitted a few minutes of black smoke in an hour; the boilers which discharged into this chimney were fitted with the most modern mechanical stokers (nearly new), and on the receipt of the notice the engineer received instructions to take the stokers off and put on another kind of appliance, which was at the time being recommended as a smoke preventer. This firm, through the serving of the notice, spent at the very least £500, and on other boilers subsequently spent twice that amount to prevent, if possible, a nuisance on their premises. This is only one instance of many that I could give of firms having spent in some instances £2000 in all kinds of appliances to try to prevent it. They have not appeared in Court, because they have done all they can, spent most liberally and ungrudgingly on anything and everything which they were told would do away with smoke. If the public only knew what had been spent to put an end to the smoke nuisance, the amount would simply startle them, and cause them to consider a little before they said nothing had been done.

What has been done in the way of experiment, invention, and investigation, say, during the last ten years?

The active agitation on this question sets the minds of men in motion to try and devise various kinds of appliances to consume smoke. The inventive faculty soon filled the market with all kinds of mechanisms, costly and complex, each owner claiming perfection for his patent. All these have been tried in their time (and they are

almost numberless), with one invariable result, viz., failure to abate the nuisance. What has, and is being tried at the present time, to prevent black smoke? To mention separately the number of smoke consumers placed upon the market would fill a book, which would hardly be worth the time wading through, because their name is legion. Some have lived, or, we might more truthfully say, have had a struggling existence for a few years, and then succumbed to the severities of the world. The majority of them have passed away very quickly after their birth, to be remembered only by the patentees, who have found them to be very costly children.

It will be well to notice the various kinds of patents before the public which have been tried for years, and are being used at the present time, with the object of preventing black smoke, and such an inquiry, we think, should convince all men that much is being done, and money spent to prevent smoke. For our purpose in this paper we may classify them under ten heads, viz.:—(1) Grids or circulars on the doors; (2) hollow bridges or split bridges; (3) hollow bars of various shapes; (4) mechanical stokers, sprinkling, and coking; (5) smoke-washing apparatuses; (6) smoke-condensing apparatuses; (7) steam jets in the furnace; (8) fuel economisers and smoke preventers; (9) forced draughts of various kinds; (10) automatic panel or lower doors.

Let us look shortly at the above-named appliances, and see how far they have proved satisfactory as smoke preventers.

GRIDS,

or circulars on the doors for admitting air to the furnace, have been deemed necessary the whole of this century, and even to-day on all new boilers the grids are to be found, proving conclusively that air is required in the furnace after firing to ignite the gases. These grids have to be opened and shut by hand as required by the firings, and if worked regularly, opened and closed at the proper time, they will prevent black smoke, if the openings are sufficiently large to admit the proper quantity of air, and the fireman fires as he ought. Many have kept to the old grids, and say, "Though it is an antiquated idea it is a good one, and nothing better if they would only work themselves," for they find sometimes the men forget, or will not work them.

The hollow bridges have had an existence, so we are told, since 1812. Some know them as split, or double bridges. They are built of metal, or brickwork, situated at the far end of the fire-bars, underneath. There is a door to which is attached a rod to open and close it. The air is admitted through the door and bridge into the tube and ignites the gases. Many are in use at the present time, but many have discontinued using them, because they destroy the draught in the furnaces by pulling the air under the bars instead of through the fire. They also state they require a lot of attention, as they are quickly filled up with ashes. This method of admitting air does cut off the smoke if attended to.

Then there are hollow bars of various kinds, which take air through them and admit it at the same point in the tubes as the hollow bridge. The air is continually going into the tubes when not necessary, in many instances 80 per cent. more than required, and because of this, and burning away quickly, they have never become very popular, although some are used at the present time.

MECHANICAL STOKERS.

There are two kinds, known as the coker and the sprinkler. The coker deposits the fuel in the front of the fire, and then works it forward. The sprinklers by a small shovel throw a little on the fire at once, distributing it over the grate bars. There are many makers of stokers, the mechanism of each varying somewhat, but in principle there is a sort of similarity. At one time many more stokers were used than at the present time. They work fairly well where regularity of power and running is required, say, for cotton and flour mills, and other similar classes of work, but where the power and running required is very irregular, they are of very little use, as they need so much attention, and because of this many large firms have abandoned them. They are very expensive, the cost of working, repairs, &c., are very heavy, and some say, who have worked them for years, that there is no saving in firemen, as the men are constantly called upon to assist them by hand.

SMOKE-WASHING APPARATUS.

This kind of apparatus has been tried in various forms; the idea being to wash the smoke after leaving the furnace, and take from it all its blackness, emitting into the atmosphere nothing but an invisible vapour. The smoke was met by sprays of water, and fan-worked beaters, which were supposed to wash out the blackness, the solids to be used for some purpose, while the fan also provided the necessary draught. This was a most expensive process, and proved impracticable, and the company which placed it on the market dissolved. Then there came after this what was called a "smoke condenser," which proved to be a very crude and unpractical idea. It consisted of large tubes, almost as big as a boiler, three in number. The chimney was dispensed with, the smoke from the boilers discharged into these tubes, No. 1 first, then No. 2, and afterwards into No. 3; then out into the atmosphere. In each of these tubes were steam jets, which met the smoke, and were supposed to condense it, the solids going into receivers, and sold for disinfectant, which the patentee claimed to be of more value than the cost of the coal. This looked well on paper, but came out badly in practice. It did destroy the smoke, but also destroyed the draught, the furnace fires almost went out, and the patent as a natural consequence went quickly out of existence.

STEAM JETS.

Steam jets are put into the boiler fumer, and other kinds of furnaces, for two purposes, (1) to force the fires, and (2) to kill the smoke. Steam to force the fires has been used for many years, especially by those whose chimneys were low, and whose draught was bad. For this purpose they have given great satisfaction. To blow the steam on the fire is admitted by many to be the proper place to apply it for increasing the evaporative power of the boiler and jet at the same time. It is a very simple arrangement, very cheap, nothing to get out of order, and if worked continuously under most conditions (both in boilers and in heating furnaces), it proves very efficient. Though

abandoned by many for a number of years, manufacturers and engineers have come to the conclusion that for a forced draught there is nothing to beat it, and they are again applying it to their boilers.

FUEL ECONOMISERS AND SMOKE PREVENTERS.

Apparatuses known by these names vary somewhat in principle and construction. Some admit air automatically at the door, and bridge also. There are levers to lift by the fireman before he is able to fire, and this the men do not like; so it is easy to conceive they have not gained much favour with the men. This kind of apparatus has been adopted very largely, and if kept in order it works fairly well. They prevent smoke, but have a tendency to cripple the draught, as the pull is divided between the door and the bridge. These machines would have had a much longer life if the men had taken to them; but entailing a little labour, workmen went dead against them, and were largely responsible for their not becoming more general in use.

FORCED DRAUGHTS.

During the last few years manufacturers have had a craze for *forced draught*. The cause of it can be attributed to patentees who have trotted out various kinds of appliances, and many people have put on a *forced draught* when their natural draught has been quite sufficient for all practical purposes, but they have been led away by the delusion that 25 per cent. could be saved by burning all sorts of rubbish. They have found out their folly afterwards, and many have returned to the natural draught again.

There are many *forced draughts* in the market to-day, each differing slightly in detail, but in principle they are practically one. How is the force applied? Nearly all of them box up the ashpit, apply from one to three steam jets under the bars, which blow the steam through the bars; some one jet through bars, one through a split bridge; others have a door in the dead plate to admit air and steam to the furnace; while others have also jets on the top of the fire. Some have dispensed with the ordinary fire-bars, and made a special bar, while others have done away with bars altogether, substituting a thick plate on which the fire rests. The steam being blown into the fire generates the heat. Some have also made special doors with holes in of various sizes to continually admit *air* with the steam. As we have already stated, there are slight differences in detail, but there is a sameness or oneness about all of them. These kind of appliances are very largely used at the present time. They are very costly, not automatic, hence their working entirely depends on the men who have to shut off the steam before firing, and turn it on afterwards.

The chief claim for this kind of apparatus is economy, by being able to burn an inferior fuel. There is much difference of opinion on this point. Some who have had them working for a length of time say, "There is a slight saving, considering all things;" while, on the other hand, others say, "There is no saving, but a loss, when the extra quantity of coal consumed is considered, extra flue cleaning, extra carting of refuse, burning away of the various parts of the apparatus, and burning of bars," and in some instances they add the "burning of the boilers." When totalled up they say the loss is considerable; and many who have spent hundreds of pounds on them, have just recently decided to go back to the natural draught, which, they say, is far more economical and in every way more efficient. Let us just look at them for a moment or two from a smoke-preventing point of view. Will they prevent black smoke? To such a question our great experience amongst them warrants us in saying, "Yes," but we would also state that it is absolutely necessary to use very great and constant care in firing in order to do so. We might truthfully say, often the man and not the machine is responsible for preventing smoke, and is thus entitled to the credit. Many users of them admit their great liability to make black smoke, and attribute it to the ashpit being boxed up, which many contend is wrong in principle. But let one with long and varied experience among all kinds of boilers speak for himself. A large firm of boiler makers in England have a patent forced draught like those spoken of, viz., two jets under the bars and in the fire. This arrangement has been working for a long time with fairly satisfactory results. When questioned as to the position of the jets, and their merits, they said, "The two jets under the bars were practically of no use, unless it was to make smoke." The jet in the furnace, they said, "was doing all the work, forcing the fires, and preventing smoke;" and when asked why they boxed up the ashpit, and put two jets under the bars, they replied, "Because the people liked them boxed up, believing by so doing they derived great benefit by economy and prevention of smoke." Such statements from experienced persons point out very clearly the value or otherwise of such methods.

As we have already stated, with care smoke can be prevented by the various kinds of forced draught, but sometimes firemen will not use exceptional care. They say, "if it is a smoke burner it ought to burn the smoke, when they carry out the working instructions, but they don't prevent it sometimes." After very bad emission of smoke from boilers which had attached to them forced draught, I have gone into the works and questioned the firemen, who said they "had worked the jets as they were instructed, yet black smoke belched forth." No doubt they will think it almost incredible when I state that frequently boilers with forced draught have emitted in one hour from four to forty minutes of black smoke, and I may say further, as a fact, the boiler with a forced draught has emitted forty-five minutes of black smoke in one hour, and the fireman swore "he had worked the jets according to the instructions." If necessary, I could quote lots of cases where the chimneys were fairly good prior to the adoption of forced draught; now they are making much more smoke, and have had to pay the penalty. What is the explanation? The boilers are the same, the work on them is the same, the men are the same, they are as careful as before, and the conditions of working in every way are the same; yet they are making more smoke since they dispensed with natural draught. I will not express an opinion, but have given the reader some facts from which he will be able to formulate the correct answer. Then there is also what is known as

PANEL, LOUVRE, OR VENETIAN STOVES,

which open and close automatically, and can be

regulated to admit the desired quantity of air to the furnace. These are very simple arrangements, easily applied to all kinds of boilers and furnaces; nothing to get out of order, and with ordinary care in firing, they work fairly well and prevent black smoke. This is a coming back to the old idea of grids, which are worked automatically, and not dependent on the fireman.

A YEAR'S PROGRESS IN SANITARY SCIENCE.*

By JOSEPH PRIESTLEY, B.A., M.D., D.P.H., &c.

(Continued from page 395.)

DIPHTHERIA STATISTICS.

Diphtheria increases steadily, and no satisfactory explanation (beyond the influence of schools) is yet forthcoming. The importance, however, of the antitoxin treatment is shown in a valuable (second) report, signed by eight (out of nine) medical superintendents of the various hospitals of the Metropolitan Asylums Board,† and published during the year, giving an account of the use of antitoxin serum in the treatment of diphtheria during 1896 (*vide* also "Medical Annual," 1897, p. 624). Of the total cases, 71·3 per cent. have been treated with antitoxin with the following results, to which are added, for comparison, the cases treated in 1895 (also partly with antitoxin), and those in 1894 (without antitoxin) :—

Day of Disease on which Treatment was commenced.	Mortalities per centum. 1896		1895		1894
	All cases.	Antitoxin cases.	All cases.	Antitoxin cases.	All cases. No antitoxin.
First day	4·7	5·2	11·7	4·6	22·5
Second day	12·8	15·0	12·5	14·8	27·0
Third day	17·7	21·9	22·0	26·2	29·4
Fourth day	22·5	27·8	25·1	33·1	31·6
Fifth and after ...	24·6	31·7	27·1	35·7	30·8
Total	20·8	25·9	22·5	28·1	29·6
Tracheotomy cases	41·0	40·6	—	—	70·4
Laryngeal cases ...	29·6	28·8	—	—	62·0
Post-scarlatinal diphtheria	5·0	5·9	—	—	—

Of the total cases (antitoxin and others), the percentage mortalities may be further sub-divided as follows :—

	1896‡	1895‡	1894
Under five years of age	30·2	34·2	47·4
Between five and twenty years of age	15·2	15·8	20·5
Twenty years and over	8·9	2·5	6·5

* Abstract of article contributed to the *Medical Annual*, 1898.

† Two thousand seven hundred and sixty-four cases were treated with antitoxin during 1896, and Dr. Gayton, of the North-Western Hospital, is the only superintendent who does not sign the report.

‡ Taking only antitoxin-treated cases, the figures are: Under five years of age, 1896, 32·2; 1895, 37·4. Between five and twenty years of age, 1896, 20·8; 1895, 21·3. Twenty years and over, 1896, 4·2; 1895, 3·9.

As to complications, there is an increase in their numbers for 1896 as compared with 1895—such increase being more apparent than real, and due to the fact that the statistics for 1896 are more exact than those of 1895, whilst with the lessened mortality, or even the mere prolongation of life, *cæteris paribus*, an increase in complications was to be expected, *i.e.*, more time is allowed for such complications to be developed.

Complications (all cases)*	1896	1894
Albuminuria	53·4	24·1
Nephritis	0·5	1·2
Paralysis (various)	21·3	13·2
Pneumonia (lobar)	0·5	0·3
Pneumonia (lobular)	2·5	1·6
Relapse	1·6	0·9

A rash in connection with the antitoxin treatment was found in 35·2 per cent., and was generally of an urticarial, erythematous, or scarlatinal type; whilst joint pains were noticed in 6·5 per cent., abscesses at seat of puncture in 1·2 per cent., and pyrexia (with or without rash or pain) in 19·8 per cent. of the cases.

ANTHRAX.

Another important report published during 1897 is that of the Anthrax Committee, who have come to the following conclusions :—

(1) Anthrax is a disease which attacks man and several of the lower animals (*e.g.*, horse, cow, sheep, goat), and is transmitted by inoculation, or by breathing and swallowing—the former known as external anthrax or malignant pustule, the latter as internal anthrax—from wool (including camel hair and goat hair), hides and skins, horse hair, and bristles.

(2) The incubation period is short—not over three days.

(3) Theoretical preventive measures consist of (*a*) exclusion of infected material from use; (*b*) disinfection; and (*c*) employment of insusceptible persons, but are practically impossible to carry out.

(4) Practical preventive measures are suggested as follows :—(*a*) Employment of persons with requisite experience; (*b*) exclusion of workers with the slightest open sores; (*c*) treatment of suspected materials by washing or disinfecting; (*d*) special ventilating precautions, *e.g.*, dust removal, adequate air space, &c.; (*e*) cleanliness of rooms, persons, and clothing.

LEPROSY.

The International Conference on Leprosy at Berlin have reported during the past year that the leprosy disease is due to the entrance into the blood of the bacilli lepræ of Hansen and Neisser. The disease exists only in man, is contagious (and not a hereditary disease), and therefore the sufferers require to be carefully isolated—compulsory isolation following notification, and careful medical inspection. Considering the scientific standing of the members and experts of this Commission their conclusions are noteworthy, and settle once and for all the life history of the disease and the means at our disposal for combating its extension.

PLAGUE.

The International Sanitary Conference, or Convention, at Venice, has also reported during the year to the following effect :—

(1) The necessity for inter-governmental notifica-

tion (by telegraph) of plague, with account of the progress of the disease, prophylactic measures adopted (inspection, isolation, disinfection, &c.), together with detailed statement of action taken (permissive) as to exportation of susceptible articles, *e.g.*, rags, body linen, clothes, and bedding, used sacks, carpets, embroidery, skins (raw fresh, untanned), animal *débris*, human hair, &c.

(2) The importance of a *daily* medical visit of all persons on board vessels leaving infected ports outside Europe with efficient disinfection of articles on board, &c., and power of keeping back any person or persons suspected of sickening for the plague.

(3) Special details as to pilgrim ships, with a particular code of rules as to pilgrimages both to the Hedjaz and up the Persian Gulf (before and during the voyage), with suggestions of necessary improvements at the various sanitary stations to which pilgrims have to go in the Red Sea.

(4) Special regulations as to terrestrial frontiers, the Red Sea, and sea routes generally.

(5) Special measures to be adopted when plague breaks out in Europe, whether by land or sea, *e.g.*, (*a*) inter-notification as to the disease, and measures of prevention taken; (*b*) particular measures to be taken in connection with infected, suspected, and healthy vessels respectively at various ports of arrival.

The incubation of plague is limited to ten days, and frontier restrictions as to quarantine, &c., are left to the various countries, States, &c., concerned.

Notification, medical inspection, and disinfection (together with improved sanitation generally) are the keynotes to the labours of the Venice Convention, and in this connection the 1897 Milroy Lectures of Dr. Collingridge (sounding the death-knell of the old quarantine) are interesting. In these Lectures the life history of quarantine is told, its legislative aspects described, and its final death related; whilst a full account is given of the means of defence against disease importation now in the hands of all Port Sanitary Authorities and their Medical Officers of Health, viz., notification, medical inspection, disinfection, and sanitation—results which are practically the outcome of various Conferences amongst the representatives of different nations, *e.g.*, Vienna, 1874; Rome, 1885; Vienna, 1892; Dresden, 1893; Paris, 1894; Venice, 1897.

VACCINATION.

No action has yet been taken by the Government to give effect to the recommendations offered in the report of the Royal Commission on Vaccination (*vide* "Medical Annual," 1897, pages 618, 619), though Sir T. Thorne and Dr. Copeman, after visiting the continental vaccine centres, have reported favourably on glycerinated (not vaselinated or lanolinated) calf vaccine lymph, and recommend that it be distributed from the National British Vaccine establishments in air-tight glass receptacles. The general adoption of calf lymph and the abolition of the arm-to-arm vaccination (except amongst members of the same family) would be an important step in the right direction, and go far to lessen the opposition of a large section of the anti-vaccinators. The same may be said as to re-vaccination, which is equally as important, as shown by the evidence submitted to the Royal Commission, who, however, whilst stating their belief in the value of primary vaccination, make no recommendation as to legislation in regard to re-vaccination—an anomalous state of affairs pointed out during the year by the Epidemiological Society of London in the form of a special resolution carried unanimously at their meeting.

Vaccinators and anti-vaccinators are prepared for action when the subject of vaccination comes before the Houses of Parliament (if it ever does), but it is doubtful what the result will be.

TYPHOID FEVER AND WATER ANALYSIS.

Serious epidemics and outbreaks of typhoid fever at Maidstone, Lynn, Clifton, and Belfast, have drawn great attention to water supplies and to the care needed to safeguard them from pollution. Prevention is always better than cure, and if the epidemic scourges of the past year give rise to improved water supplies, not only in the towns concerned, but also amongst Sanitary Authorities generally, they will prove to be real blessings. That the water supplies used by certain Sanitary Authorities are far from satisfactory goes without saying, and the difficulties that arise from water supplies being in some cases in the hands of private companies (who seem to have an objection to interference in the way of inspection, &c., by the officers of a Sanitary Authority) appear to be well-nigh insurmountable. The Stockport Corporation, as a Sanitary Authority, is suggesting petitioning Parliament for compulsory powers of inspection and examination of water supplies by their officers, and such powers might with advantage be granted to all Sanitary Authorities. It remains, however, to be seen what view Parliament will take of the subject. The relative values of chemical and bacteriological analyses of water have naturally been also much discussed during the year, with the result that both the chemist and bacteriologist are apparently necessary, and must give their analyses of a water before a sound conclusion can be arrived at. In certain cases a chemical analysis alone would fail; in other cases, a bacteriological. One thing, however, appears certain, and that is the very greatest importance to be attached to the periodical examination and inspection of the sources, and the knowledge of the history of a water supply, together with the protection of the area around such sources.

(*To be continued.*)

THE PROTECTION OF SURFACE WELLS FROM POLLUTION.

By Adam Morris, Assoc. San. Inst., Sanitary Inspector County of Roxburgh.

To protect the water of a surface well from pollution, the well should be lined with bricks or clean stones, well built, and set in cement. This steining should be carried above the surface of the ground to a height of at least 1ft., to keep any surface washings from entering the well. Koch has recommended, as an effectual means of protecting well water from occasional surface pollution, that an additional lining of impervious clay puddle should be carried round the well, between the retaining wall and the subsoil; this puddle wall to be carried down to a depth of 10ft. Before reaching the water of a well so protected, any surface contamination would thus be filtered through the soil, the organic impurities being presumably nitrified by the action of the life (bacteriological and vegetable), at the

surface of the soil. There is also an amount of mechanical filtration. That this method of protection is often efficient I can testify from my own experience, but it will only answer where the surface pollution is comparatively small and intermittent, and where there is abundance of life in the soil. Where the soil is saturated with polluting organic matters, so as to kill the purifying agents in it, or where there are leaking drains or cesspools in the near vicinity of a well, the above-named method will be of little use.

Perhaps the most satisfactory manner of protecting a surface well is to carry the puddle lining already described round the outside of the well, and as far as possible into the water-bearing stratum. This method will effectually prevent any surface pollution in the immediate neighbourhood from soaking into the well. Subsoil water, however, frequently travels long distances after meeting with an obstacle to its percolation into the earth, and, if it has passed through a soil which has contained much refuse matter, it may carry polluted water to wells which might be looked upon otherwise as in good and safe situations. It should distinctly be understood that no amount of so-called protection of a surface well will be of the slightest use in improving the safety and quality of the water if the sub-soil water is obtained from a soil that is filth-saturated with the refuse accumulations of years, or if badly-constructed drains and cesspools are voiding their contents into the subsoil to intermix with the subsoil water. In such case, and more especially when analysis of the water shows pollution from organic sources, the only safe method to adopt is to close and fill up the well, and obtain a fresh supply from a pure source.

It should also be remembered that the flow of the subsoil water is almost invariably towards rivers and watercourses. Surface wells are sometimes sunk on flat low-lying land near rivers or streams, the prevalent idea being that water will find its way to the well from the river or stream, subjecting itself to a process of natural filtration and purification in its passage. This idea is generally erroneous, as in almost every instance the flow is from the well to the river. This is important, for where a well lies low, or in a natural basin, the land of which is cultivated and manured, or where the farm steading is at no considerable distance away on rising land, the well will in all probability receive a large share of the natural drainage, and consequently the water will be dangerous to use.

All wells should be closely covered with stone flags set firmly with good cement. On no account should wood covers be used, as they decay rapidly, and pollute the water. A pump should be provided —either an ordinary suction pump or a force pump, according to the height to which the water has to be lifted—and a properly constructed socket-jointed pipe drain should be laid from beneath the pump to a point some distance below the well, to carry away all surplus water and surface washings, and so prevent the possibility of their return to the well.

POLMONT.—The engineer's estimate for the proposed water supply for the district is £5000. Meetings are being held for the purpose of presenting a requisition to the County Council.

Reviews.

Vaccination a Delusion. Its Penal Enforcement a Crime. By ALFRED RUSSELL WALLACE, LL.D., Dubl., D.C.L., Oxon., F.R.S., &c. Swan, Sonnenschein & Co., Limited. Price 1s. 92 pp.

THIS essay is one written primarily for the purpose of influencing Parliament and securing the abolition of the vaccination laws. The author has collected a considerable amount of information on the subject from the Reports of the Royal Commission and the Registrar-General, and he claims that he abundantly proves, doubtless to his own satisfaction, that in all previous legislation our legislators have been misled by facts and figures that are untrue, and by promises that have been unfulfilled, and that similar statements have characterised the whole official advocacy of vaccination from the time of Jenner to the present; and, moreover, that all official statements as to vaccination are *untrustworthy*. While we are unable to agree with many of the conclusions at which the author arrives, we cannot withhold expressing our opinion that he has written ably and conscientiously on a subject which is of such a controversial character.

Premature Burial: Fact or Fiction? By DAVID WALSH, M.D., Edin. Price 1s. 6d. Bailliere, Tindall, and Cox. 49 pp.

THIS little *brochure* has been compiled in part, we believe, as a reply to a pamphlet entitled "Premature Burial," by W. Tebb and E. S. Vollum, M.D., which is on the affirmative side of the subject, and partly to counteract the sensational paragraph writers of our daily newspapers. The author has, in our opinion, succeeded in showing that the possibility of being buried alive is very remote, hardly amounting to a probability, and only then when hasty burials may be necessary, as in hot countries, upon battlefields, and in time of plagues. After examining from a medical standpoint many of the wonderful narratives which have been published in newspapers and books, of persons being buried alive, and subjecting them to careful scrutiny, he arrives at the conclusion that the mass of reported cases of premature burial is worthless from the point of view of exact evidence.

Handbook of the Workmen's Compensation Act, 1897; with approved Schemes of Compensation; Statutes referred to; Notes on Accidents; Negligence and Misconduct; Employers and Workmen's Liability. By M. ROBERTS-JONES, Barrister-at-Law. Price 2s. 6d. Fifth edition. Cardiff: *Western Mail*, Limited. London: 82, Fleet-street. Demy 8vo., 82 pp.

THIS is an excellent little manual by a gentleman who is well qualified to write on the subject which he evidently has warmly at heart. The Workmen's Compensation Act, 1897, comes into operation on the 1st July next, and as it affects a large number of employers of labour — including Urban and District Councils—who require to be conversant with its provisions, the book will be found of considerable value to them, being, as it is, annotated, and also containing extracts from the speeches of

members of the Government, which show the intentions of the Legislature in framing it. Surveyors of Local Authorities will need to have an acquaintance with the Act, inasmuch as workmen suffering accidents, whilst employed on engineering works, including excavating, road repairing, drain laying, &c., will be able to claim compensation. To them, and to all employers of labour, we can heartily recommend this edition of the Act, as it is clear, concise, and well-arranged.

Annotations from Annual Reports.

Inspection of Bakehouses.—Dr. E. Hugh Snell, Medical Officer of Health, Coventry, alludes in his annual report to the tangled intricacies of the Factory and Workshop Acts, which he contends "do much less to ameliorate unhealthy conditions than was probably intended by their framers. The present condition of affairs is also fostered, so far as this city is concerned, by the paucity of skilled assistance in the way of Inspectors which is available for the regular inspection of bakehouses, without neglecting other more urgent duties. It is certainly desirable that the bakehouses should be inspected regularly several times a year. Under the present circumstances this is an impossibility. In many I find that too little attention is paid to general cleanliness. Lime-washing and cleansing is in some done regularly ; in others this is not so. In a number of instances there is no possible contrivance to aid ventilation, except the occasional opening of the door. I have found that there is a very general lack of information among occupiers concerning the fact that there are regulations affecting the management of bakehouses which can be enforced."

Why Hygiene Should be Taught in Schools.—This question comes prominently to the fore in the report of Dr. Henry Kenwood, M.B., L R.C.P., Medical Officer of Health St. Mary, Stoke Newington. The excessive mortality in his district, he points out, was furnished entirely by summer diarrhœa, measles, and whooping-cough, among the infant population ; it was practically restricted to the children of the poorer classes, and was largely due to parental ignorance and neglect of the elementary laws of health and disease prevention. When our system of education also concerns itself with teaching every scholar the vital matters which are of the first importance to the individual and the community—even to the sacrifice of some of the purely ornamental matter that is now taught, the sooner will every parent in the land possess the knowledge that will help them to put into operation the essential laws of health and the rudimentary principles of infant rearing ; and then there will come a great reduction in the infantile mortality. The increase due to diphtheria was also a factor in promoting the excessive death-rate for the quarter referred to, and he is convinced that some of the increased mortality from this disease may be attributed to the manner in which children, of the most susceptible ages for the infection, are crowded together into our elementary schools, without any sufficient attempt—as by the systematic medical inspection of scholars—to ensure that they are free from infection. It is admittedly a difficult matter to put into operation, but the sort of medical inspection required may be—from his own experience—very rapidly performed, and with very little hindrance to school work, and it is already being practised on a large scale in America, with the most promising results.

INCORPORATED
Society of Medical Officers of Health.

THE SANITARY SUPERVISION OF SCHOOLS.

Dr. E. Seaton, Medical Officer of Health to the Surrey County Council, the president, occupied the chair at the last meeting of the session held by the Incorporated Society of Medical Officers of Health on Friday evening last, at the Board-room of the St. Giles' District Board of Works, High Holborn. There was a good attendance, those present including Dr. R. Dudfield, Dr. T. Groves, Dr. L. C. Parkes, Drs. S. Davies, T. Barley, J. S. Tew, T. Carr, Mr. Wolff Defries, Drs. E. Chissolm, W. Gruggan, H. Stott, E. F. Willoughby, R. W. D. Mair, L. F. Bryett, H. B. Collins, S. R. Lovett, A. Newsholme, E. A. Dorrell, and Dr. F. J. Allan, hon. secretary.

Dr. Edmund Gwynn, Medical Officer of Health to the Vestry of Hampstead, was unanimously chosen as President of the Society for the ensuing year, which will commence in October next.

A conference of delegates representing various societies interested in public health was recently convened by the Society of Medical Officers of Health for the purpose of considering the question of the new Vaccination Bill in its relations to sanitation and sanitary work. The following resolutions were adopted at the conference, and being now submitted to the Society, were unanimously endorsed and confirmed :—

(1) That the age limit within which a child should be vaccinated after birth should be six months.

(2) That evidence of efficient vaccination should be afforded on the admission of a child to a public elementary school.

(3) That a clause should be inserted in the Act defining "efficient" vaccination.

(4) That it is essential that the State should take steps to require the re-vaccination of all persons on their attaining the age of twelve years.

(5) That the powers and duties with regard to vaccination should be transferred from the Poor Law to the Sanitary Authorities.

(6) That the Government should pay for vaccination performed by general medical practitioners, subject to the vaccination being done in accordance with the regulations of the Local Government Board, and being open to inspection.

Dr. R. Dudfield, Medical Officer of Health, Paddington, read a paper on "The Sanitary Supervision of Schools," which dealt particularly with overcrowding in schools, and the limitation of the spread of infectious disease. It could not be denied, he said, that school attendance plays an important part in the spread of those infectious diseases to which children are most prone, and therefore there could be no difference of opinion that every effort

should be made to ensure that compulsory education should be carried out under conditions which shall not only minimise the possibilities of the spread of disease, but also in no way prejudice the health and vigour of the scholars in later life. At the present time overcrowding was perhaps one of the conditions most generally accepted as prejudicial to health, and it was therefore surprising to find that the Education Department tacitly, if not willingly, allowed overcrowding to occur in the schools under its jurisdiction. In support of this statement, Dr. Dudfield quoted at length from the Education Code. The maximum cubic space per child provided for was 120ft., and 96 cubic feet as a minimum, but the only standard prescribed by law is that under the Factory and Workshop Act, 1895, which is 250 cubic feet for day work, and 400 cubic feet overtime. The contrast was marked, and the circumstances demanded attention. The only grounds for such a scanty allowance for a child was that there was a difference in the amount of the impurities of the expired air and exhalations of a child as compared with those of an adult. But children could not bear the chilling effects of draughts as well as adults, and were more susceptible to the ill-effects of vitiated atmosphere. With 120 cubic feet air space per child it would be necessary on the theoretical standard of permissible respiratory impurity to renew the air of a school-room twenty-five times during the course of an hour. According to Du Chaumont three changes in the hour are as many as can be safely and comfortably borne. Dr. Dudfield then examined the School Code with regard to attendances, and showed there was much elasticity in respect of attendance in excess of accommodation, through the desire to prevent the exclusion of scholars simply on the ground that any given room is full. Under Article 78 it was prescribed that a child should be refused admission on "reasonable grounds" only, and the fact that a room or class was full did not appear to the Education Department a reasonable ground for such refusal. They held that the child should be admitted, and that temporary overcrowding be abated by a re-arrangement of the classes. The sanitary aspects of this overcrowding occupied a secondary position. So long as every child was caught in the school net and found a place in a class not too much in excess of the legal number for which the teacher is certified, due regard being paid to the "skill, health, and energy of the teacher," the influences which may react to the detriment of the child's health and vital powers may be set aside pending the necessary re-organisation of the classes, if that be possible. Only a small proportion of the children attended regularly, and the teacher was tempted to make up the average whenever possible. Indeed, it seemed to be an impression among teachers that under Article 73 they were allowed to overcrowd the school-rooms to an extent not exceeding 15 per cent. of the certified accommodation, which was doubtless a wrong interpretation. Among the considerations to which he wished to draw attention, was—What is the range of infectivity of those infectious diseases to which children are most predisposed, such as measles; and how far does the vitiated atmosphere of the school-room favour the spread of such diseases? Many children were continuously under the influence of vitiated atmosphere, their homes being unfortunately as bad as the schools with respect to air space. Dr. Ransome's recent experiments in the cultivation of the tubercle bacillus on papers saturated with moisture condensed from the breaths of persons in health and disease, suggested serious thoughts with regard to overcrowded school-rooms containing children, some of whom might be incubating disease. All Medical Officers of Health had arrived at the conclusion that something should be done to limit the spread of measles and whooping-cough, but they had not yet agreed upon the best course. It seemed to him that the code should provide for the systematic notification by teachers and school visitors. There should be complete interchange of information between the Medical Officers of Health of adjacent Authorities with a view to anticipating the progress of disease from one district to another. Having dealt with the question of disinfecting after measles, Dr. Dudfield said it should be made law that no children belonging to a family infected with measles should be allowed outside the house or tenement until the family had been declared free from infection. With family isolation and disinfection he believed that much might be done to limit the spread of measles. There was also need for securing uniformity as to the duration of exclusion from school, and he thought there ought to be a schedule of quarantine periods. As the probability of action by the Local Government Board was remote, he thought the Society might take the matter up and issue a schedule to the Medical Officers of Health. In concluding, he submitted the following resolutions for the consideration of the Society:—

(1) That this Society is of opinion that no scholars in excess of the number for which such room is certified should be assembled in any class-room of a public elementary school for the purpose of instruction.

(2) That this Society is of opinion that active measures are needed for the limitation of the spread of infectious diseases not included in the schedule of diseases to be notified, and with that object recommends:—(*a*) That a school teacher excluding a scholar on account of the existence of measles or whooping-cough, either in such scholar or in the home of such scholar, and a School Attendance Officer on discovering the existence of any of the said diseases in the home of any scholar should forthwith notify the Medical Officer of Health of the district in which such scholar resides of the existence of such disease; and (*b*) that no scholar excluded from school on account of measles or whooping-cough, as set out in the preceding resolution, should be re-admitted to school until the Medical Officer of Health of the district in which such scholar resides shall have certified that the home and articles therein likely to retain infection had been adequately disinfected.

(3) That this Society is of opinion that an official table of definite periods of quarantine is needed for the guidance of school teachers and officers.

(4) That this Society, recognising the importance of maintaining the efficiency of all public elementary schools, is of opinion that Article 1101 of the Education Code should be amended to allow of a school counting the attendances of any scholar excluded on the certificate of the Medical Officer of Health in which the scholar resides during the period covered by such exclusion.

Dr. F. J. ALLAN read a number of letters from

members who were unable to attend, expressing their views on the subject of the resolutions.

Dr. L. C. PARKES supported the resolutions, and said that the paper had been an extremely useful one. He thought they might go further than Dr. Dudfield, and lay down some definite figure for the minimum air space, say not less than 200ft. cubic space. The present arrangements were totally inadequate. He had been preparing statistics, which showed that there was an epidemic period for measles about every two years, and he thought that this knowledge now being pretty well ascertained, the infant departments of the public elementary schools should be closed when the epidemic first threatened. He believed by this method the spread of the disease would be checked, if not entirely stopped.

Dr. NEWSHOLME gave particulars of arrangements at Brighton, by which the teachers at once notified the absence of scholars through infectious disease.

Dr. WILLOUGHBY said that in Ontario the Government Department came to the conclusion that a minimum air space of 250 cubic feet should be the standard, and this was adopted in all Canadian schools.

Drs. J. S. TEW and H. STOTT explained the circumstances pertaining to rural parishes, the latter remarking that the Education Department should be impressed with the necessity of proper heating and ventilation arrangements in the schools.

Dr. S. DAVIES sincerely hoped that some practical steps would follow the practical paper Dr. Dudfield had given them, and he would be prepared to move an amendment to the first resolution defining the limit of 200 cubic feet.

Drs. GROVES and COLLINS having spoken,

Dr. PARKES suggested that the resolution should go to the Council, who should be empowered to formulate a memorial to the Education Department, and that it should be printed in separate form so that every member of the Society could sign it. This would make it a powerful memorial which ought to carry weight with the Government.

Dr. DUDFIELD replied to some of the points raised, and expressed his willingness to adopt the suggestion to refer the matter to the Council on the understanding that the resolutions remained intact as a basis on which the Council could work in preparing the memorial.

The resolutions accordingly stated referred to the Council, and a hearty vote of thanks to Dr. Dudfield for his paper, passed on the motion of the PRESIDENT, closed the meeting.

PORTMAGEE.—At a recent meeting of the Cahirciveen Board of Guardians a long discussion took place as to the outbreak of fever at Portmagee. It was pointed out that the number of cases was increasing, and the source of the disease was attributed to the bad water supply and the unsanitary condition of the village. A letter was read from the Congested Districts Board pointing out that it could not give a grant towards the proposed water supply. It was proposed to ask Trinity College to make a sewerage drain in connection with the back yards of the houses.

Sanitary Inspectors' Associations.

THE NORTH-WESTERN AND MIDLAND.

THE annual meeting of the above Association was held at the Liverpool Royal Institution on Saturday last, the 16th inst. There was a good attendance of members, including representatives from Liverpool, Manchester, Crewe, Waterloo, Formby, Birkdale, St. Helens, Wallasey, Urmiston, Lymm, &c. The chair was taken at the commencement of the proceedings by Mr. William Urquhart, Crewe, the retiring chairman. After the transaction of the routine business, the Chairman announced that the Council had unanimously selected Mr. William Stansfield, Chief Sanitary Inspector, Manchester, as its Chairman, and that it was his pleasing duty to formally install Mr. Stansfield into his new position.

Mr. STANSFIELD expressed his keen appreciation of the honour conferred upon him, and promised to lose no opportunity of furthering the interests of the Association.

Messrs. Sydney Bayliss (Birmingham), James Walton (Manchester), and John Roberts (Llanrwst), having been elected to membership, and Messrs. James J. Topping and Fred Woodward, West Bromwich, to associate membership, and some additional nominations having been received, the Hon. Secretary was called upon to read the eleventh annual report of the Council.

The Council expressed its gratification at the continued success which had attended the work of the Association during the past session. Seventy-two additional names had been placed on the roll, which now comprised 32 honorary members, 226 members, and 15 associate members, or a grand total of 273. The area of membership had similarly increased, 115 distinct urban and rural sanitary districts being represented, as compared with 87 in the preceding year. The validity of the claim of the Association to being the representative body of Sanitary Inspectors in the North-Western and Midland districts had been strengthened in many respects. Negociations for amalgamation with the Sanitary Inspectors' Association for Carnarvonshire had been carried to a successful issue, and the prospects of the Association in North Wales were of a most favourable description.

Fifteen sessional meetings had been held, and had been characterised by a greatly-improved attendance. Several of the meetings were record ones—notably the highly-successful public conference of Sanitary Inspectors, convened by the Association, and held at Birmingham in October last.

High appreciation was expressed of the great services rendered by the President, Dr. Vacher, during the past year, and warm thanks given to the authors of the lectures and papers which had been delivered, and to the Editor of THE SANITARY RECORD for the liberal space he had afforded for reports of meetings of the Association.

The treasurer's statement having been read, the report and statement were unanimously adopted.

On the motion of Mr. BLAND (Urmston), seconded by Mr. R. LOWE (St. Helens) a hearty vote of thanks was unanimously accorded to the past Chairman of Council, Mr. W. Urquhart

(Crewe), and to Messrs. N. Coates, and H. H. Spears, the hon. treasurer and secretary respectively of the Association, for their services. The vote was acknowledged in suitable terms by the members concerned.

The election of officers was then proceeded with, and in view of the approaching reorganisation of the Association, it was unanimously resolved that the honorary officers should all be re-elected. Dr. Francis Vacher, Medical Officer of Health, Cheshire C.C., therefore becomes again the President of the Association, Drs. Hope, M.O.H, Liverpool; E. Sergeant, Lancs. C.C; Geo. Keir, Staffs. C.C.; and W. Carter, Liverpool, Vice-presidents. Chairman of Council, Mr. Wm. Stansfield; Vice-chairmen, Messrs. E. Worrall (Penmaenmawr), F. T. Poulson (Stafford), and W. Bland (Urmston); Librarian, W. E. Gleave (Liverpool); Hon. treasurer, N. Coates; Auditors and Scrutineers, D. B. Cowden and R. Dacres; Hon Secretary, H. H. Spears (Waterloo).

At the conclusion of the general business, a special meeting of the Association was held to consider the new scheme for reorganisation submitted by the Council. The proposed amendments to rules were considered *seriatim*, and at some length, but with the exception of one or two trifling verbal alterations, the scheme was unanimously approved, and the rules ordered to be amended in pursuance therewith.

Under the new scheme the local work of the Association will be carried on by district centres, of which three are at present formed, viz., North-Western (embracing Lancashire and Cheshire), Midland, and North Wales.

Four general meetings of the Association are to be held in each year, and in so far as is practicable, are to be held alternately in the respective districts of the local centres. The election of members, hon. members, and associates, is to take place at the general meetings of the whole Association, but applications for membership are to be approved in the first instance by the members of the local centre in whose area the applicant resides. The management of the Association is to be vested in a Central Executive Council, to be elected annually, and to consist of (*a*) the chairman and secretary of each district centre *ex-officio*, and (*b*) representatives directly elected by each district centre in the proportion of one councillor for the first thirty names on the books, and an additional representative for each succeeding fifty names. Meetings of the Central Executive Council are to be held on the same dates and places as the general meetings of the Association, and Councillors are to be paid their actual third-class railway fare when journeying by train to the place of meeting. Subscriptions are to be collected locally, but are to be transmitted to the Treasurer of the Association, and the administration of the finances is to be vested in the Central Council, who are to defray the current and authorised expenses of the district centres. The various district centres are to have full control of their own district business, and to elect their own district officers and councils.

The annual meeting and conference under the new constitution was fixed for July 1st and 2nd, and will in all probability be held at Manchester.

Having regard to the thoroughly broad, liberal, and representative nature of the amended constitution, the Council and officers are of opinion that a large number of Inspectors will be attracted to the Association, and that its future progress is assured.

NATIONAL REGISTRATION OF PLUMBERS.

THE eighth annual meeting of registered plumbers in the Glasgow and West of Scotland district was held on Thursday, the 14th inst., in the Accountants' Hall, when there was a good attendance. In the unavoidable absence of the president, ex-Bailie Crawford, the chair was occupied by Bailie James Dick. The annual report of the District Council was submitted. In it the Council stated, "During the period now to be reported on the Council are glad to say that the movement has continued to progress satisfactorily. It is true that the Parliamentary measure to which they, in common with the Worshipful Company of Plumbers, and with the other councils throughout the United Kingdom, and with all who are interested in the public health, attach so much value, has not yet found a place upon the statute book; but meanwhile the public sense of the importance and responsibility of the plumber's calling grows and deepens, and the education of the young plumber and hall-marking of qualified masters and operatives go on apace. With these influences at work all over the country, the Council look forward with every confidence, not only to the early passing of the Plumbers' Registration Bill into law, but to the solid and increasing advantages which are being, and will be, yearly gained by the registration movement alike for the trade and for the general community."

The report gave full details of the educational work carried on by the Council in theoretical and practical plumbing classes in Glasgow and Ayr. The Glasgow theoretical classes were now in their tenth session, and the place of Mr. David Fulton, whose premature removal was deplored, had been ably taken by Mr. Alexander Dalrymple, the number of students enrolled being 176. In the Glasgow practical class, conducted by Mr. Francis M'Culloch, the number enrolled this session is 93. At Ayr the classes were now in their fifth session, the enrolments in the theoretical class conducted by Mr. Dalrymple being 40, and the practical class conducted by Mr. Duncan Lamont 19. The Ayrshire County Council had again renewed its grant of £75, and Ayr Town Council that of £10. It was hoped that with the assistance of Greenock Town Council the class for that district might be resumed next winter.

The report also dealt with other matters connected with the movement, including the Plumbers' Registration Bill, which has been re-introduced this session, and which passed through the stages of second reading and Committee last year, but was unfortunately lost through the third reading not coming up until July 7th, which was the last day available for private members. The report also noticed the recent issue of the model regulations and bye-laws prepared by the six District Councils in Scotland, which was the result of much labour and exhaustive discussion. The Worshipful Company of Plumbers had borne the entire cost of production, and had also placed a copy in the hands of the chairmen and officials of all Local

Authorities in Scotland, explaining that the code aims at serving as a compendium of the most approved principles and methods which the scientific inquiry and practical experience of the last fifteen years have evolved as applicable to the drainage and plumbing work of buildings, and at placing in the hands of Local Authorities in burghs and counties a model for their guidance in framing regulations on the important matters dealt with, and also offering permission to any public body duly applying therefor to the publishers, through the District Councils, to make use of the whole or any part of it in drawing up sanitary bye-laws under any statutory powers with which they are invested.

The report concluded by a reference to the annual Scottish Plumbing Congress, which is to be held this year in Glasgow, on the 18th, 19th, and 20th August, and for which the Corporation have granted the free use of the Corporation Galleries, Sauchiehal-street.

On the motion of the CHAIRMAN, seconded by Mr. ALEXANDER BROWN, the report was unanimously adopted. Messrs. James Anderson, J. L. Arnot, Robert Stevenson, James Kilpatrick, and Charles Hegney, jun., master plumbers; Messrs. Andrew Johnstone, William Laing, Thomas Ewing, James Dickie, and Alexander Young, operative plumbers; and Professor John Glaister, M.D., Robert Scott, John Gordon, W. F. Salmon, and Professor Jamieson, public representatives, were chosen to fill the vacancies on the District Council; while ex-Bailie Crawford was re-elected president; Mr. John Gordon, I.A., vice-president; Mr. Archibald Craig, secretary and treasurer; and Messrs. J. L. Arnot and W. A. Rattray, auditors. The proceedings concluded with a vote of thanks to the chairman, proposed by Mr. Laing.

Diphtheria in Worcester.—Dr. Wilfred W. E. Fletcher has presented to the Local Government Board a report on the extensive and prolonged epidemic of diphtheria which prevailed in Worcester during the year 1896, and on the sanitary administration of the city. He states that in 1896 319 cases of diphtheria were notified, of which 49 terminated fatally, according to the Medical Officer of Health, and 51 according to the Registrar-General. During the first half of the year 1897 52 cases of diphtheria were notified, and of these 12 terminated fatally. No common cause of the prevalence could be discovered. The disease was not confined to any particular district, nor could it be attributed to any specially unwholesome circumstances in the portions of the city in which it was chiefly prevalent; indeed, the children, mostly of the poorer classes, who lived in the oldest and most unhealthy parts of the city, seem to have been only very slightly affected by the epidemic. Dr. Fletcher considers that, although the Worcester Town Council have been unusually dilatory in providing sewage outfall works, they have been active in other directions, and much good work has resulted during recent years. Thus, while the Town Council are deserving of severe censure on account of their indifference to the serious pollution of the Severn during many years, by the discharge into the river of the whole of the crude sewage from the city, they are to be commended for much good work in other respects.

Institute of Sanitary Engineers

THE ESCAPE INTO LIVING-ROOMS OF THE PRODUCTS OF COMBUSTION FROM COAL FIRES THROUGH DEFECTIVE CHIMNEYS.

By F. BALL, F.I.S.E., Southwold, Suffolk.

IN the course of my practice as a Sanitary Engineer, it has been my lot, on several occasions, to discover nuisances and dangers to health, instances of which I have not seen recorded, but which I think to be of sufficient importance to justify this paper on the subject.

I do not claim to be the discoverer of a new source of nuisance, for no doubt other Sanitary Engineers have had experience of it as well as myself; but from the absence of records of cases in the sanitary publications, I think the subject has not received the attention it demands. The nuisance alluded to is, from the escape into living-rooms of the products of combustion from coal fires through defective chimney flues. You all know the chemical constituents of common coal and their poisonous nature, and you can readily conceive that the constant breathing of air containing these poisonous gases must be injurious to health. It is analogous to breathing air contaminated with sewer gas, which, if not directly conveying the germs of disease, is admitted to lower the vitality of the human organism and render it less able to resist attacks of disease.

The first case of this evil brought to my notice was at a country mansion in Oxfordshire some fifteen years' since. The house was built of bricks, stuccoed on the exterior, and apparently in a good state of repair, except that the stucco on one of the chimney stacks was cracked and bulged out away from the brickwork.

For many years an unpleasant smell had been noticed in the house, more especially in the drawing-room and bedroom over. The smell being imputed to defective sanitation, an architect was consulted, who had all old fittings removed, and new ones of the best pattern fixed, drains re-laid and ventilated. All water-closets were next the external wall, with soil pipes outside continued to roof and ventilated. Waste pipes discharged over gullies, and there was not a drain in the house.

Still the nuisance was not abated, and the occupant, an elderly lady, who slept in the bedroom over the drawing-room, was continually ailing from sickness and headache. The doctor in attendance concluded the smell in the rooms was the cause of the sickness, because on leaving home for change of air, and even when occupying rooms in a different part of the house, the lady regained good health; but on returning to her old apartments, the sickness came on again.

The sanitary arrangements having been put into good order, the smell was attributed to dead rats or mice under the floors, but on searching none could be found. At the doctor's request I was called in and made an examination of the sanitary arrangements and floors, but without finding anything wrong with the former, or any dead animals under the latter. There was, however, a very strong smell as of unpurified gas in some of the rooms.

Under the floor of the drawing-room the plaster and joists were discoloured with soot, whilst dark lines appeared round the skirting at the fire-place end of the room. Further search disclosed that the recesses formed by the projection of the chimney in the drawing-room were hidden by a framed partition, canvassed and papered, fixed in line with the chimney breast in order to form a straight wall at that end of the room. No use was made of the enclosed spaces, but access was had through a narrow door, which was papered over like the rest of the wall.

On examining the sides of the chimney in these enclosures I found the plaster off in patches, much cracked, and the joints of the brickwork unsound in places; whilst the very strong smell and the accumulation of soot on the edges of the cracks afforded strong evidence of the escape of the products of combustion from the flues. Following this chimney up in the roof the defects were quite as visible. In one place a lath was put through a joint right into the flue, and a current of air was coming through sufficiently strong to deflect the flame of a candle to a horizontal position. This air from the chimney circulated over all the bedroom ceilings. Above the roof, where the stucco was cracked and loose on the chimney stack, the smell was quite strong; whilst soot was accumulated in the cracks. At some previous time alterations had been made at the house, rooms added, and the roof raised. In making these alterations, the trimmers, gutter beds, and flashing had been removed, in doing which damage was done and not made good. This chimney contained four flues, one of which was the kitchen flue, and this from its more constant use and larger consumption of fuel was the worst offender. The flues were 14in. square, capped with terra-cotta pots. They suffered from down-draught at times, the house being on the side of a hill, and overtopped by trees at the back.

Having satisfied the doctor and the occupants of the house that the nuisance was from the gases escaping from the defective flues, a remedy was applied, which, from motives of economy, was not of a very substantial nature, although it has proved effective down to the present time. The remedy consisted of taking down the flue partitions, scraping off soot and old plaster, re-building partitions, plastering all round as the building proceeded, the angles being well filled up to make the flues somewhat round in section. In order to know the result after fifteen years' wear, I wrote to the owner a few months since for information, and received a reply stating that the smell has never reappeared.

The second case was at a house in Upper Seymour-street, London. In this house a smell was observed in the dining-room, which could not be accounted for. The room was at the back of the house on the ground floor, and over the kitchen and scullery. The drainage and sanitary fittings were of the best, and the gas fittings were sound. The family doctor took me to the house and showed me the sanitary arrangements, which had been carried out under his directions, and were sound and good. In the dining-room—the only place where a smell was complained of—the nuisance was greatest near the fire-place, which led me to examine the chimney, when I found the smell proceeded from the bell lever and the skirting below. The lever box was let into the brickwork, which was the front wall of the scullery flue. In cutting away the brickwork to let in the lever box, it had been damaged and the mortar joints shaken, and not made good with plaster. The joints were also loose behind the skirting, apparently from fixing a bell crank. One can readily understand that damage can be done by a careless workman in cutting into 4½in. brickwork of a chimney flue, and in the absence of careful pointing and plastering after, there would be a way for the chimney gases to escape. The doctor was quite satisfied as to this being the cause of the smell, especially as he had noticed a slight cloudiness from smoke in the room at times.

A third case was at a house in Suffolk, in which settlements had caused cracks in the walls and chimney in a bedroom. The cracks in the chimney breast were not large, but the edges were discoloured by soot, and they emitted the smell of unpurified gas, as in the other cases. A gas bracket was fixed to the chimney, and was thought to be the cause of the smell, although a gasfitter had been called in no end of times to stop the leakage, but without result. The occupant, on placing his nose at the cracks, was convinced the smell proceeded from them, and not from the gas bracket.

I have met with other cases, but those mentioned are sufficient to prove that defective chimneys exist, and are a source of nuisance and danger to health. Considering that the walls of chimneys are generally but a half-brick thick; that settlements take place, alterations are made, wooden plugs driven to support pictures, mirrors, and other objects, it is no wonder that flues become defective and allow the gases to escape. Gases ascending a flue can escape through cracks just as the gas does in a pipe which is unsound. There is a slight pressure of gases in a flue by reason of the area of the exit at the top being less than that of the inlet at the bottom, and the expansion through heat of the cold air rushing in above the fire. Then the suction action of fires burning in rooms with doors and windows closed, is sufficiently strong to draw air from every crevice, including those in defective flues.

From the accumulation of sooty particles in the crevices round the edges of skirting and like places, the unconsumed carbon or smoke appears to be arrested in its passage, leaving the invisible gases to escape, and the absence of smoke throws off suspicion from the true cause. In the first case cited, which was by far the worst, no smoke was noticeable in the rooms, although soot was collected on the plaster, the canvas back of partitions, and under the floors. That flues become defective from various causes, and chimney gases escape into rooms, I have proved. That these gases are a nuisance from their odour, and that they are dangerous to health when continually breathed, even in a very diluted form, few can deny.

RYHILL.—A Local Government Board inquiry has been held into the application of the Hemsworth Rural District Council for sanction to borrow the sums of £1695 and £698 for a supply of water for the townships of Havercroft and Ryhill respectively, and the Council having apportioned the cost of the proposed work as above stated, the Overseers of Havercroft appealed against the apportionment to the Local Government Board.

General News.

MORECAMBE.—The cottage hospital scheme is again coming into prominence.

MANCHESTER.—The City Council has decided to borrow £27,000 for the enlargement of the Monsalt Infectious Diseases Hospital.

DURHAM.—The advisability of erecting a new infectious diseases hospital is under consideration by the Health Committee of the Town Council.

LEOMINSTER.—The Town Council has decided to apply to the Local Government Board for permission to borrow £1500 for the new water scheme.

TOWYN.—The subscriptions for the proposed cottage hospital are coming in apace, and there is every probability of the work being begun shortly.

ALTRINCHAM.—The Urban District Council has decided to provide a destructor—the chimney to be 150ft.—at a cost of £800, or with the site, from £2500 to £3000.

LONDON, W.—Out of 609 samples of food, drink, and drugs analysed by the Marylebone Public Analyst during the past year only five were found to be adulterated—two samples of milk and three of butter.

SAUGHALL.—It is understood that as soon as the statutory time given to the Wirral Water Company expires, strenuous efforts will be made to provide the village with an adequate supply of pure water.

CROMER.—A Local Government Board inquiry has been held into an application of the Urban District Council to borrow £2000 for the purchase of land and the erection thereon of an infectious diseases hospital.

BELFAST.—The Corporation has authorised a Committee to take the necessary steps to have the proposed alterations and extensions at the abattoirs carried out—necessitated by the recent extension of the city—which it is estimated will cost £8000.

CARDIFF.—The County Council has decided to apply to the Local Government Board for sanction to the borrowing of £21,600, being £21,000 for the erection of new wards and other additions to the sanatorium buildings and £600 for furnishing such additional premises.

CARLISLE.—The Town Council has decided to include pulmonary phthisis, tubercular meningitis, and tabes mesenterica among the infectious diseases to be notified in the city. The attention of the Medical Officer would thus be called to them, and he would be able to inquire and see if the disease could be traced to the milk supply.

KING'S NORTON.—In the twenty-fifth annual report of the sanitary condition of the area of the King's Norton District Council, the Medical Officer (Dr. F. Hollingshead) deprecated the practice of "tipping" refuse on the roadway. The construction of houses had gone on at a very rapid rate, plans for no less than 1136 houses having been passed during the year. He strongly advised the Authority to adopt the "destructor" as a means of destroying and converting refuse into harmless material. In this way not only would a serious nuisance be abandoned, but material of a useful character provided for the roads.

SELKIRK.—The ratepayers have under discussion a resolution of the Commissioners to introduce a new supply of water by gravitation from Lewinshope and Scaddow Burns, about seven miles up Yarrow. The proposed scheme, when completed, is estimated to cost £17,200, and the supply from 160,000 to 180,000 gallons per day, or about 28 gallons per head per day of the population.

WEDNESBURY.—The Borough Surveyor has been instructed to prepare plans for the erection of a temporary isolation hospital with a permanent fence upon the land belonging to the Corporation near the Lodge Holes. The land forming the site of the existing hospital is to be sold, and the proceeds of the sale are to be devoted to the erection and equipment of the proposed new isolation hospital.

Personal.

MR. J. EVANS has been appointed Inspector of Nuisances for the borough of Carmarthen.

MR. W. H. BESWICK will shortly resign the post of Surveyor for the urban district of Exmouth.

MR. J. HARVEY has been appointed Inspector of Nuisances for the urban district of Swadlincote.

MR. H. MACKAY has been appointed Medical Officer for the south-east district of Sheffield union.

MR. P. C. DORMER has been appointed Inspector of Nuisances for the urban district of Raunds.

MR. A. E. Prescott, Deputy Surveyor, Luton, has been appointed Surveyor to Douglas Town Council, at a salary of £200 a year.

MR. H. R. BURNETT, has been selected by the Barrow-in-Furness Town Council to fill the post of Borough Electrical Engineer.

MR. EDWARD ASTBURY, of Buckley, has been appointed Surveyor for the Buckley urban district at a salary of £100 per annum.

MR. ARTHUR ROTHERA, of Sowerby Bridge, has been appointed to the post of Surveying Assistant to the Rawtenstall Town Council, at a salary of £85 per annum.

MR. E. W. COZENS HARDY has resigned the surveyorship to the St. Faiths (Norfolk) Rural District Council, having been appointed to a similar post at Seisdon (Staffs.).

CHARLES J. MYERS, M.R.C.S., L.S.A., has been appointed Medical Officer of Health for the rural district of Louth, vice Dr. R. Dowenichetti, hon. physician to the Queen, resigned.

MR. FRED. THORPE, assistant gas manager to the Widnes Corporation, has been appointed as gas manager for Colne, in succession to Mr. Symmonds, at a salary of £225 per annum.

MR. J. P. HORSFIELD is shortly leaving King William's Town, Cape Colony, to take up the appointment of Sanitary Inspector at Salisbury, Mashonaland. He will be the first Sanitary Inspector there.

MR. GORDON BRYANT, assistant engineer at the Electric Lighting Station, Yarmouth, has been appointed chief engineer in succession to Mr. A. W. Ranken, resigned. His salary is to be at the rate of £175 a year for the first six months.

Sewerage Schemes.

[To Municipal Engineers and Surveyors.—The Editor will be pleased to receive items for publication relating to sewerage schemes projected or inaugurated, together with explanatory diagrams or photographs. The former should be drawn and lettered in black ink.]

The Higham Ferrers Town Council has decided to apply for a further loan of £146 for the sewerage works.

The Local Government Board has sanctioned the borrowing of £236 for the sewerage works at Pendleton.

The Urban District Council of Chesterton has decided to apply to the Local Government Board for permission to borrow a further sum of £350 for sewerage works.

The Local Government Board has sanctioned the borrowing by the Alnwick Council of the sum of £700 for works of sewerage and sewage disposal for the township of Warkworth.

A new filter-bed is to be constructed at Northampton, according to plans by Mr. Emson, at an estimated cost of £5500; £3000 for the filter-bed, and £2500 for filtering material.

The Urban District Council of Tunstall has adopted plans and estimates of a new sewerage and sewage disposal scheme, and has decided to apply for a loan of £22,977 15s. 11d.

The Heywood Town Council has decided that the available land at the sewage works at Botany be laid out for filtration purposes, in accordance with the recommendations of the engineer.

The Town Council of Monmouth has decided to apply for powers to borrow an additional £10,000 for the purpose of completing the drainage portion of the combined scheme for drainage and electric light.

A Local Government Board inquiry has been held at Stowmarket as to the application of the District Council and the East Stow Rural District Council for sanction to the borrowing of £5100 for the purpose of a joint scheme of sewerage and sewage disposal for the urban district and parishes of Stowupland and Combs.

The Vestry Clerk of Camberwell recently wrote the Greenwich District Board stating that, owing to the complaints that were continually being received with regard to emanations from the road surface ventilators, the Vestry had decided to convene a conference of representatives from the Sanitary Authorities of South London on the subject of sewer ventilation, with a view to combined action in reference to the matter, and stating that the conference had been fixed for Wednesday, May 4th.

The Bourne Rural District Council has decided not to proceed with the drainage scheme for the village of Horbling, Lincolnshire, as proposed by Mr. Radford, C.E., of Nottingham. This provided for a sewerage farm at a cost of £1300, exclusive of maintenance. An alternative and less expensive scheme is under consideration. The Parish Council protested against the outlay.

At a recent meeting of the Coventry City Council the City Engineer reported that the contractor for the construction of the outfall sewer, rising mains, &c., in connection with the Lodge Farm sewage disposal scheme, had commenced operations. It was decided that Mr. Samuel Toon be appointed Inspector to superintend the laying and jointing of the pipes under this contract at a salary of £150 per annum.

Mr. Bosley, Superintendent of the Guildford outfall works, has reported to the Town Council that during the past two years the expenditure on the farm for horse hire, occasional labour, and general farm expenses, amounted to £86 10s. 2d., and the returns amounted to £149 13s. 3d., showing a profit for the two years of £63 3s. 1d. The whole of the works were maintained in good order, and the effluent continued to be a good sample.

A special meeting of the Belfast City Council was held last week to make an order under the provisions of the County Antrim and Belfast Borough Act, 1865; the Belfast Borough Act, 1868; the Local Government Board (Ireland) Provisional Order (Belfast) Confirmation Act, 1873; and the Belfast Improvement Act, 1878, that a portion of the city shall thenceforth constitute a separate drainage district, to be called the Ligoniel district.

Lighting.

The Local Government Board has sanctioned the loan of £30,000 for the electric lighting of Carlisle.

The Manchester City Council has decided to borrow £150,000, subject to the approval of the Local Government Board, for electrical works.

The Milton-next-Sittingbourne District Council has reduced the price of gas from 3s. 4d. to 2s. 11d. for private lighting, and from 3s. 4d. to 3s. for public lighting.

The Amsterdam City Council has decided to take over the gasworks. To meet the cost the issue of 3½ per cent. municipal bonds to the amount of 18,000,000fl. has been decided upon.

It is understood that the electric light is being introduced into the Picture Gallery at Holyrood Palace, in view of the residence at the palace next month of the Earl of Leven and Melville, the Lord High Commissioner.

THE foundation stone of the new Wycombe electric light works was to have been laid last Saturday by Mr. R. S. Wood, Chairman of the Electric Light Committee of the Wycombe Town Council.

ON the recommendation of the Lighting Committee of Buckie Council the Police Commissioners have instructed their surveyor to prepare an estimate of the cost of lighting Buckpool with acetylene gas.

PROFESSOR ROBINSON'S report on the electric lighting question at King's Lynn was received by the Town Council last week, and it was decided to apply to the Local Government Board for sanction to a loan of £30,000 for electric lighting in the town.

AT a recent meeting of the Watching, Lighting, and Fires Committee of Aberdeen Town Council it was resolved to extend the overhead system of electric lamps in George-street, between Loch-street and Hutcheon-street, at an estimated cost of £230.

A LOCAL Government Board inquiry has been held at Egremont relative to an application by the Wallasey Urban District Council for powers to borrow £20,795 for purposes of electric light extension, £5600 for new water mains and other purposes, and £1182 for certain street improvements.

A REPORT on the question of an electric light installation in Gourock has been presented to the Burgh Commission. It states that the estimated cost of laying an installation would be about £8600, including plant sufficient to light the whole of the burgh and the erection of sixteen arc lamps along Shore and Kempock-streets.

MR. R. F. YORKE recently submitted his report on the water-power available at the Touch reservoirs for the electric lighting of the town to the Police Commissioners of Stirling. Mr. Yorke finds that by utilising the available water-power the Commissioners may obtain a constant guaranteed output of 54 brake horse-power from the turbines, which, after allowing for losses in the dynamo, cable, and electric storage, is capable of producing a supply of 618 units per day, which is sufficient for supplying the extended area of the town with 8000 lamps of 8-candle power connected, or one lamp for every two inhabitants. If in the future additional power was required it could be obtained from No. 4 reservoir, at present untapped, to the extent of 4000 more lamps. The capital outlay is estimated at £13,500, and allowing £675 per annum for interest and sinking fund, which was 5 per cent. on the capital outlay, made the total annual cost on the undertaking £1325. Taking 100,000 units as the number to be sold per annum, and charging at the rate of 4½d. per unit (which was considered to be equivalent to gas at 2s. 6d. per 1000 cubic feet), the revenue produced would be £1875 per annum, thus leaving a clear profit of £550.

THE Town Council of Stirling has unanimously resolved to oppose the Gas Company's Bill, which was passed by the House of Lords' Committee, before the Committee of the House of Commons.

THE Yarmouth Town Council has resolved to apply to the Local Government Board for sanction to a further loan of £4800 to increase the lengths of mains and sub-stations for the electric lighting of the town. The items in the application will be:—Steam engine, 150 kilowatt alternator and steam pipes, £2800; additional high and low-tension mains, £1600; transformers and transformer stations, £400. The present sanctions amount to £35,200, and the sanction now proposed to be asked for will make the amount of the loans £40,000. The Council has also resolved that Mr. Preece be consulting engineer for the new engine and alternator.

THE Gas and Electricity Committee of the Bradford Corporation has decided to make substantial reductions in the price of electric current, both for lighting and for motive power. The scale at present in operation provides for a charge of 5d. per Board of Trade unit for lighting and 2½d. per unit for motive power. The Committee has decided to recommend the Town Council to reduce the charge for lighting to 4½d. per unit and to adopt a new scale for motive power. This will provide that for a minimum of four hours' continuous use with a consumption of 550 Board of Trade units the charge shall be reduced to 2d. per unit, with intermediate reductions up to eight hours' continuous use and 1200 units' consumption, at which the charge will be 1d. per unit.

HACKNEY is desirous of emulating the example set by St. Pancras. A "town's meeting" of the ratepayers was held on Monday night at the Hackney Town Hall to ascertain the opinion of the inhabitants on the proposed selling of the electric lighting order to a limited company. Mr. George Chambers, the chairman of the Vestry, presided. Mr. B. Dent moved the first resolution as follows:—"That this meeting is of opinion that it would be detrimental to the best interests of the ratepayers of Hackney to part with the electric lighting order, and therefore recommends the Vestry to keep the order in its own hands. This meeting further hereby protests against the creation of an electric lighting monopoly in Hackney." Mr. H. J. Taylor seconded, and said that London had had enough of monopoly in gas, water, and trams. Mr. Lampard, L.C.C., and others followed in favour of the resolution. Mr. Henry Holland, the chairman of the Electric Lighting Committee, argued that the Vestry could re-purchase the order at the end of twelve years as a going concern, and that if the proposed scheme was carried out the company would collect the house refuse to be consumed at the generating station and save the parish £5000 a year. The prices to be charged by the company in Hackney would be considerably lower than in other London districts. The chairman put the resolution, and declared it carried by fifty to three. It will be interesting to note the value attached by the Vestry to the passing of this resolution.

THE estimates of the Manchester Corporation Gas Committee for the year ending on the 31st March next were submitted and approved at a recent meeting. On the profit and loss account the estimated expenditure reaches £509,300, including £228,000 for cannel coal and oil, £45,000 for retortmen's wages, £60,000 for repairs and maintenance of works and mains, £30,000 for salaries and wages of clerks and inspectors, £36,500 for interest on loans, and £27,921 as a contribution to the sinking fund in liquidation of debt. The receipts are expected to produce £560,500, made up chiefly of £475,000 from gas rents, £40,000 from coke, £26,000 from tar, and £19,000 from ammonia water. There will thus be a surplus payable to the City Fund for the relief of the rates of £51,200.

A DISCLAIMER.

(*To the Editor of* THE SANITARY RECORD.)

SIR,—It has come to the knowledge of the Directors of Dr. Tibbles' Vi-Cocoa (1898) Limited, that a report is in circulation that a Mr. Harness is in some way connected with or interested in the business of Dr. Tibbles' Vi-Cocoa (1898) Limited. Will you permit me to contradict this report publicly in your columns? It is wholly without foundation. I speak with authority on the matter, for I am now Secretary to the present Vi-Cocoa Company; I was Secretary to the former Vi-Cocoa Company during the whole period of its existence; and I was in the employ of the owners of the business before either Company was formed. Hence I am in a position to state positively that no person of the name of Harness has ever been in any way concerned or interested or in any way connected with that business or either Company.—Yours faithfully,

G. BROOKE SMALLEY,
Secretary to Dr. Tibbles' Vi-Cocoa (1898) Ltd.
60, 61, and 62, Bunhill-row, London, E.C.,
April 13th, 1898.

Notes and Queries.

Subscribers have the privilege of obtaining advice in this column on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed to THE EDITOR, "Notes and Queries," THE SANITARY RECORD, 5, Fetter-lane, London, E.C.

NOTE.—If an answer be required immediately, a stamped addressed envelope must be enclosed, when we will endeavour to furnish a copy of the answer by post, as owing to the large number of queries received we cannot guarantee the insertion of a reply in the succeeding issue.

1042.—DRAINS TO NEW BUILDINGS: TESTING.—"J. H." writes:—"I should be glad to know what is the practice with regard to testing drains to new houses, or re-laying of old drains. Do you consider the testing of the drains by the hydraulic or water test sufficient?"

Answer.—The practice with all Authorities of repute is to require that new drains be tested with the hydraulic or water test when laid and before being covered up. Inasmuch, however, as it often happens that the water-closet pans, gullies, &c., are not connected to the drains when the trenches are open, and as the drain pipes may be disturbed in the act of filling, it is necessary and most desirable, when the house is finally inspected before occupation, that the drains be again tested by the smoke test applied by the smoke machine. We have seen so many instances where the water-closet pans within houses have been found to be improperly connected to the drain or soil pipe, and the latter improperly constructed within the house, which would not otherwise than by the use of the smoke test be discovered, that we should not advise any surveyor or Inspector to certify that a house is fit for, or permit its, occupation until such test is carried out. If this practice be insisted on in all cases it will save much subsequent trouble.

1043.—SEWAGE DISPOSAL FOR SMALL VILLAGE: SCHEME PROPOSED.—"Q." writes:—"The sewage from a small village in my district discharges into a ditch, causing a serious nuisance. It is impossible, even by going an unreasonable distance, to enable the sewage to be applied to land, and I am at a loss to know what is the best plan to adopt. Pumping could, of course, be resorted to, but the expense for such a small scheme for 150 inhabitants is prohibitive. The only practical method, so far as I can see, is to filter the sewage; and this I propose to do by constructing duplicate tanks at the outfall, 20ft. by 4ft. by 4ft., which I consider would efficiently deal with the sewage of the place, estimated at 1200 gallons per day. Inasmuch, however, as the outlet of the filter would be at the top, and thus prevent any arrangement for automatically emptying it, I am uncertain as to whether it is absolutely necessary for its efficiency that constant and continual rest should be given each filter, turn by turn, or whether a periodical rest of every alternate week would be sufficient to secure a good effluent. The difficulties are enhanced by the close proximity of the river, which is affected at the proposed outfall by most tides, but not by all."

Answer.—The scheme proposed by our correspondent, of passing the sewage over the surface of material intended, if we understand him properly, to serve as a filter, is impracticable, and would result in failure. If a filter is intended to serve the purpose for which it is constructed, namely, to purify sewage, it must be provided with means of drainage from the bottom. Therefore, if this cannot be carried out, it is useless to construct it. Biological filters should be worked with intelligence. The sewage must be applied for a few hours at a time only, or at the longest not more than a day, and should be followed with a rest period equal to the period at which it has been under work. If this principle be not followed out, the filter will in a very short space of time become choked up, which can only be remedied by giving it a

very prolonged period of rest. It should always be borne in mind that biological filters must be looked upon as an evolution of the system of land filtration, and that, by a process of selection of suitable material, a filtrant of several feet in depth can be made to do higher duty than is possible in natural soil, which has often a filtrant of only a few inches in depth. In each case, however, it is to be understood that purification is effected by biological agency. It appears to us that, under the circumstances named by our correspondent, the septic tank process would probably be best suited to the requirements, as this system requires very little fall, and the tank may be constructed underground, without detriment, while the biological filters, which are used in conjunction with the septic tank, may be constructed only a few inches in depth.

1044.—Water Main in Connection with Sewer: Danger of Pollution from.—"Subscriber" writes:—"In a certain town several of the sewers are flushed by means of a sluice attached to the water main. The pressure thus obtained proves a most effectual means of flushing. But the question has been raised as to the possibility of sewer gas entering the main, and thus proving a source of contamination to the water supply. Of course, if the sluice is not properly closed such might be the case, but is there any danger during the time the sluice is open and the flushing in operation? I would further ask if this practice of flushing from the main is an isolated one, or is it general in other towns?"

Answer.—If we understand our correspondent properly, the water main is connected directly into a manhole or some part of the sewer, and a sluice valve is provided closely contiguous to the sewer, which is not trapped off from the water main in any way. Such a system is very objectionable, and is liable to cause pollution of the water in the street mains. There is not so much danger of pollution when the mains are under pressure, and while flushing is being carried out, but it is when the water is turned off at the main, for repairs or any other cause, that danger is to be apprehended. It rarely happens that sluice valves are in perfect working order so as to exclude leakage. When, therefore, the water is turned off at the main, a partial vacuum is formed in the pipes and air is drawn, or more properly forced into them, and at such times sewer air will find a ready means of access through the imperfect sluice valve, and mix with the water for general distribution when the supply is again turned on. We are not aware of any other instance than that named by our correspondent where the sewers are in direct communication with the water mains. There would be little objection to the supply being led into a flushing tank such as those used in conjunction with Rogers', Field's, Miller's, or Adam's flushing syphons, as in such cases the water service is disconnected from the sewer by means of a water-trap in the flushing tank.

1045.—Sanitary Institute Examinations: Dates of.—"G. W." writes:—"Will you be good enough to inform me what are the dates of the forthcoming Examinations of the Sanitary Institute?"

Answer.—From the calendar of the Sanitary Institute, which is issued quarterly, the following dates for examinations in Practical Sanitary Science and for Inspectors of Nuisances are, we find at present, fixed, viz.:—London, May 6th and 7th; Leeds, June 10th and 11th; Belfast, June 24th and 25th; Cardiff, July 8th and 9th; Liverpool, July 29th and 30th. Additional particulars may be obtained from the Secretary, The Sanitary Institute, Parkes Museum, Margaret-street, London, W.

1046.—Building Bye-laws: Power of Local Authority to Disapprove Plans.—"A. S. I." writes:—"I prepared a complete set of drawings and tracings for additions and alterations to an hotel in this neighbourhood, and submitted same to the District Council for approval, which were on three sheets, viz., ground plan and first-floor plans on one sheet, sections on another, and block plan on the third sheet. I marked all drains and connections in full. Excepting the block plan, which was drawn to a scale of 40ft. to the inch, the other plans were drawn to a scale of 8ft. to the inch. The Council have disapproved the plans, on the ground that all the plans and sections should be on one sheet. Query, (1) Can the Council require the several plans to be submitted on one sheet? (2) Can they object if I paste the plans on one sheet? (3) What is my best course to take in the matter? (4) Is there a book published giving full particulars on Building Bye-laws, and in relation to plans, &c.?"

Answer.—(1) If the plans are in conformity with the Bye-laws of the Council the latter are not enabled to refuse their approval on the grounds named by our correspondent. Neither is the Council enabled to require that plans must be submitted on one sheet as described. (2) No, if the plans are otherwise in conformity with the Bye-laws. (3) Assuming that the Bye-laws are complied with, the owner may proceed with the erection of the building, giving the usual notice of date of commencement to construct the building, at the expiration of one month from the date when the plans were first deposited. If there is no infringement of the Bye-laws the Local Authority cannot interfere, seeing that he has deposited the necessary plans. (4) Knight's "Annotated Edition of the Model Bye-laws," price 12s. 6d., obtainable of the Sanitary Publishing Company, post free, will probably be found very helpful to our correspondent.

1047.—Nuisance Caused by Offensive Trade: Procedure.—"Variola" writes:—"A man is in the habit of bringing dead horses and cows, dropped calves, &c., on to premises within this borough, and there cutting them up, and removing hide, bones, and offal to different places for sale. The surrounding inhabitants complain of the abominable smells. I have no evidence of his ever slaughtering or killing an animal there—in fact, the evidence is strong the other way. The Town Clerk says, in the absence of that evidence we cannot take up a case for using an unlicensed place as a knacker's yard or slaughterhouse, and asks me to take the case under some other Act. I would like to know what other Act we can proceed under. I have pointed out that I think it worth while trying the case under the Towns Improvement Clauses Act and Knackers Acts, for it is not the actual slaughtering or taking away the life of the beast which causes annoyance, but the subsequent cutting up, boning, and removal of offal."

Answer.—We should not advise that proceedings be taken for keeping an unlicensed slaughter-house, nor for keeping an unlicensed knacker's yard, as there is no proof that animals are slaughtered in the yard. Inasmuch as a "knacker" is held to be a person who slaughters horses, we think it could not be held that the premises are used for the purposes of a knacker's yard, for which a licence is required under the Knackers Act, 1786, and which licence is obtainable from a District Council under Sec. 27 of the Local Government Act, 1894. Proceedings may, however, be taken under Sec. 114 of the Public Health Act, 1875, against the occupier. Under this section it is provided that where any "building or place used for any trade, business, process, or manufacture causing effluvia is certified to any Urban Authority by their Medical Officer of Health, or by any two legally qualified medical practitioners, or by any ten inhabitants of the district of such Urban Authority to be a nuisance or injurious to the health of any inhabitants of the district, such Urban Authority shall direct complaint to be made before a justice," &c. It may be observed that if the effluvia amount to a nuisance in the sense of causing annoyance and discomfort, it is sufficient to bring the trade within this section, without providing also that injury to health results from such effluvia. See Malton Board of Health *v.* Malton Farmers' Manure Company, 40 L.T. (N.S.), 755; 44 J.P., 155. In Houldershaw *v.* Martin, 49 J.P., 179; 1 T.L.R., 323, it

was held that the Medical Officer's certificate under this section was sufficient, though it stated simply that a fried-fish shop was a nuisance, and did not further state that it was injurious to health. It has also to be observed that the Local Authority, on receipt of the certificates named, have no alternative but to proceed against the person causing the nuisance, the words of the section being imperative.

1048.—Sale of Food and Drugs Acts: Query No. 1037.—"T. W." writes:—"May I draw your attention to an error which appears in the answer to this query (No. 1037) in your issue of April 15th, where it states: 'It is also provided by Sec. 13 *of the Public Health Act*, 1875.' Should this not be read as 'by Sec. 13 of the Sale of Food and Drugs Act, 1875?"

Answer.—We are very much obliged to our correspondent for drawing attention to the error, which is obviously a clerical one. Sec. 13 of the Sale of Food and Drugs Act, 1875, as will be seen from the context, is meant, and Query No. 1037 must be read subject to this correction.

1049.—Sewer in Bed of Stream.—"H." writes:—"It is intended to purify a stream by providing an intercepting sewer to catch all sewage drains now discharging into it. Owing to a number of obstacles on the banks of the stream, it is thought advisable to put the intercepting sewer below the bed of the stream. Will you please inform me (1) if there is any objection to such a course? (2) What depth should the sewer be laid below the bed of the stream? (3) What is the best method of jointing earthenware pipes, so as to exclude water from the stream getting into the new sewer? (4) What is the best means of connecting the branch drains to the sewer under such circumstances?"

Answer.—(1) Beyond the patent fact that the construction of a sewer under the bed of a stream is, especially where there is much volume of water, somewhat costly, there is no objection, when proper precautions are taken to ensure sound construction, to such a course. (2) The depth at which the sewer is to be laid must depend upon local circumstances, and also upon the material to be used in the construction of the sewer. If an iron pipe sewer be constructed, the crown of this may be level with the bed of the stream, providing this bed is not of a shifting character. On the other hand, if stoneware pipes are to be used, they must be embedded in cement concrete of a thickness equal to the diameter of the sewer, and the upper part of the concrete should preferably be kept slightly below the bed of the stream. (3) Providing the sewer can be laid so that, while laying, the trenches are free from water, ordinary cement joints may be used. Otherwise special joints, such as Sykes' patent joint or Hassall's patent joint, should be used. In any case, however, the pipes must be protected by concrete in addition. (4) The branch drains will be most conveniently connected by the use of Sykes' patent screw joint, and screw stoppers may be inserted in the junctions until the branch drains are ready for connection. The manufacturers of the Sykes patent joint pipes are the Albion Clay Company, 18, New Bridge-street, London, E.C.

INSURANCE.

£250 REWARD.

Some malicious opponents have been propagating a libel to the effect that Dr. Tibbles' Vi-Cocoa, Ltd., have been prosecuted and fined for adulteration.

It is needless to say that these statements are absolutely devoid of a particle of truth, and any person who will enable the Company to secure a conviction against anyone making this statement will receive the above reward.

MARTIN & NICHOLSON (Solicitors),
29, Queen Street, Cannon Street, London, E.C.

April, 1898.

Contracts Open.

The dates given below are the latest up to which tenders can be received.

ADLINGTON (LANCS.). — April 25th. — Pipes and Gullies. — Mr. Thomas Farnworth, Council Offices, Adlington, Lancashire.

BURY (LANCS.).—April 25th.—Sanitary Tubes, &c.—Mr. J. Cartwright, M.I.C.E., borough engineer.

SOUTH WEALD (BILLERICAY, ESSEX).—April 25th.—Drain.—Mr. G. Lapwoods, Tower-hill, Brentwood.

WATERFORD.—April 25th.—Sewer Pipes, &c.—Mr. James J. Feeley, town clerk, Town Hall, Waterford.

ANNFIELD PLAIN.—April 26th.—Sewer.—Mr. T. J. Trowsdale, surveyor, Annfield Plain.

BARNOLDSWICK. — April 26th. — Scavenging. — Mr. Charles Thornton, clerk, Nelson.

BURTON-UPON-TRENT. — April 26th.—Sewers, &c.—Mr. George T. Lynam, borough engineer, Burton-on-Trent.

KNOTTINGLEY.—April 26th.—Sewerage Works—Extension of Time.—Mr. John Richardson, M.I.C.E., engineer to the Council, 5, Central Bank Chambers, Leeds.

EGREMONT (CHESHIRE).—April 26th.—Sewers.—Mr. W. H. Travers, Public Offices, Church-street, Egremont, Cheshire.

STAPLEFORD AND SHARDLOW. — April 27th. — Sewerage Works.—Mr. W. H. Radford, C.E., Angel-row, Nottingham.

HASLEMERE (SURREY). — April 27th. — Sewerage Works.—Messrs. R. B. Grantham and Son, 23, Northumberland Avenue, London, W.C.

BARNSTAPLE.—April 30th.—Sewer.—Mr. Jas. Bosson, town clerk, Municipal Buildings, Barnstaple.

STALYBRIDGE.—May 2nd.—Sewers, &c.—Mr. J. N. White, Town Hall, Stalybridge.

Vacancies.

BOROUGH ENGINEER'S ASSISTANT (CARDIFF, April 30th).—For the Corporation of Cardiff. Salary £2 10s. per week. Mr. J. L. Wheatley, town clerk, Town Hall, Cardiff.

CLERK OF WORKS (BARNSTAPLE, April 30th).—For the Town Council. Mr. James Bosson, town clerk, Municipal Buildings, Barnstaple.

CLERK OF WORKS (LONDON, S.W., April 28th).—For the London County Council. Salary £4 4s. a week. Forms of application can be obtained at the offices, Spring-gardens, S.W. Clerk of the London County Council, Spring-gardens, S.W.

CLERK OF WORKS (SOUTHAMPTON, April 27th).—For the Corporation. Salary £3 3s. per week. Mr. George. B. Nalder, town clerk, Municipal Offices, Southampton.

DRAUGHTSMAN (LONDON, S.W., April 25th).—For the London County Council. Salary £3 a week. Application forms to be obtained from the offices, Spring-gardens, S.W.

ENGINEER (LONDONDERRY, May 3rd). — For the Corporation. Sir R. Newman Chambers, town clerk, Guildhall, Londonderry.

INSPECTOR OF NUISANCES (STROUD, April 30th).—For the Urban District Council. Salary £100 per annum. Mr. Percy Witchell, clerk, Stroud.

SURVEYOR AND INSPECTOR OF NUISANCES, &c. (HAYWARDS HEATH, SUSSEX, April 26th) —For the Urban District Council. Salaries will be £70 per annum as Surveyor and £40 as Inspector of Nuisances. Mr. Edward Waugh, clerk, Haywards Heath.

To Surveyors, Sanitary Inspectors, &c.—First-class Cycles at reasonable prices. Don't place your orders elsewhere until you have seen our post-free catalogue.—MELROSE CYCLE COMPANY, Coventry.

DR. TIBBLES' VI-COCOA.

ARTICLE No. 5.

IT IS A TRUE FOOD.

THE name Vi-Cocoa means strength or force-giving cocoa. Ordinary cocoa does not restore energy after a long and fatiguing walk, or produce a refreshed feeling after a series of business or domestic worries. This is the peculiar attribute of tea and coffee, and is considered to be largely if not entirely due to the active principle, caffeine, which they contain.

Caffeine has the property of increasing the action of the heart, as well as of acting on the kidneys. It thus increases the current of blood to the jaded brain as well as to the extremities, and communicates a feeling of well-being. By its action on the kidneys it also removes the waste products of muscular exertion and other substances, which tend to cause a feeling of dulness and inertness if retained in the blood. Cocoa does not contain caffeine, but only theobromine. But although tea and coffee both contain caffeine, they also contain small quantities of other bodies, which in some individuals produce unpleasant symptoms. Thus Ceylon and Indian tea is apt to cause (much more than China tea) a feeling of nervousness, or even indigestion, and a wakefulness that is very distressing, especially if taken late in the evening. Coffee also in some people causes costiveness, and in others the reverse.

Kola nuts, or kola beans, as they are sometimes called, are the seeds of a West African tree belonging to the same family as cocoa, but differ from cocoa in containing caffeine, and are free from any injurious ingredient whatever. The idea therefore occurred to Dr. Tibbles of adding kola to cocoa, and thus adding caffeine to it, so as to confer on it the advantages of tea and coffee without their disadvantages. Recognising also the value of malt and hops in the national drinks, ale and beer, and the fact that teetotallers are a very large and increasing body, he conceived the notion of adding these ingredients to cocoa, and of thus making a palatable, invigorating, "grateful and comforting" drink that should embrace the flavour of cocoa, the restorative properties of tea, the tonic and sedative properties of the hop, and the digestive properties of malt.

Malt and hops are too well known, both to the public and to the medical profession to need recommendation. The enormous amount of malt extract that has been prescribed of late years indicates the value of malt, quite apart from the alcohol with which it is associated in ale.

The difference in the stimulant action of caffeine and alcohol is very remarkable. Alcohol by dilating the minute vessels of the skin and by thus producing a flow of blood to the surface, causes a sensation of temporary warmth to be experienced, but it has the disadvantage of dulling the intellect. Caffeine, on the other hand, increases the pumping power of the heart, and so causes a healthy flow of blood to every part, stimulating the brain, causing a renewed feeling of vigour and alertness.

Anyone who has experienced the difference between the effects of a cup of strong coffee and a glass of whisky and water during a long railway journey on a cold day will recognise the truth that coffee produces a more permanent warmth than alcohol.

Although kola contains caffeine (as well as theobromine, the active principle of cocoa) it has no aroma of its own. By mixing it with cocoa, therefore, the physiological advantages of tea and coffee are added to the cocoa. Kola also contains starch, which, when rendered soluble by the ferments of the saliva and pancreas is a true food.

Malt possesses a ferment called diastase, which has the same property of rendering starch soluble. The association of malt with kola in Vi-Cocoa is therefore remarkably appropriate, and renders that beverage especially suitable to those in whom the digestion of starchy food is diminished by a lowered vitality, or from other causes.

The Proprietors of Tibbles' Vi-Cocoa guarantee that each package is absolutely beneficial to the most delicate invalid or the youngest infant.

A little book containing the reports of the very highest medical experts and analysts in the United Kingdom, showing the advantages of Tibbles' Vi-Cocoa over all other food products, will be forwarded post free on application (a post-card will do) to any medical man, along with a large sample tin.

Address—DR. TIBBLES' VI-COCOA, LIMITED, 60, 61, and 62, Bunhill-row, London, E.C.

SANITARY INSTITUTE EXAMINATIONS.

TUITION BY CORRESPONDENCE.

An Engineer and Surveyor (Mem. San. Inst.), Certificated Surveyor and Inspector, prepares students for these Exams. by Correspondence through the post.

Fees strictly moderate. Cramming studiously avoided.

The course of tuition is arranged so as not only to qualify the student for passing the exams., but what is of equal importance, viz., that he may become a thoroughly efficient Inspector.

On successfully passing the exams., all possible assistance and advice is given to help forward intending candidates for public offices.

Many of my old pupils are now filling positions with salaries of over £120 a year.

For terms, &c., address "C. E.," care SANITARY RECORD, 5. Fetter-lane, London, E.C.

SANITARY ASSOCIATION OF SCOTLAND

EXAMINATIONS IN SANITARY SCIENCE.

Examinations for Certificates of Competency in Sanitary Science are held each year as follows, viz.:—In Glasgow in April, in Edinburgh in October, and at such other time and place as the Board of Examiners may determine.

Entrance Fee £2 2s.

For further particulars apply to

GEORGE MIDDLETON, M.A., LL.B.,
Writer, 92, Bath Street, Glasgow,
Secretary to the Board of Examiners.

A Stamped Addressed Envelope must accompany all letters requiring an answer.

SANITARY INSTITUTE EXAMINATIONS.

SPECIAL Corresponding Classes for the **Practical Sanitary Science,** and **Sanitary Inspectors' Examinations** of the **Sanitary Institute, 1898,** conducted by a gentleman holding appointments as Urban District Council Engineer and Sanitary Inspector, holder of three certificates from the Sanitary Institute, First-class Honour Medallist Hygiene, &c. Hundreds of successes.—For all particulars, testimonials, &c., apply Mem. San. Inst., Office of THE SANITARY RECORD, 5, Fetter-lane, London E.C.

OFFICIAL ADVERTISEMENTS.

CITY OF SHEFFIELD.

WANTED, an INSPECTOR of NUISANCES.

Salary £104, with uniform (if without experience, £84).

Must hold Inspectors' certificate and have thorough knowledge of Building and Draining.

Applications, stating age and qualifications, together with a copy of three recent testimonials, to be sent, on or before April 26th, to the MEDICAL OFFICER of HEALTH, Town Hall, Sheffield, and endorsed "Sanitary Inspector."

BOROUGH OF ROYAL LEAMINGTON SPA.

TOWN COUNCIL

ASSISTANT INSPECTOR OF NUISANCES.

The TOWN COUNCIL of this Borough REQUIRE an ASSISTANT INSPECTOR of NUISANCES.

No application will be entertained except from duly qualified men, possessing the certificates of the Sanitary Institute.

The salary will commence at £80, increasing £5 per annum to £100, and the person appointed will be required to enter upon his duties as early as possible.

Applications, endorsed "Assistant Inspector of Nuisances," to be forwarded to me on or before the 27th April, together with copies only of recent testimonials.

H. CONSETT PASSMAN,
Town Clerk.

THE

PENSION QUESTION SOLVED

How Public Health Officials may Secure a Pension in Ten, Fifteen, or Twenty Years of from £10 to £100 or more per annum.

This question is admittedly one of paramount importance to all Public Health Officials who are dependent upon their own exertions to provide for the future, and one which has for some time exercised the minds of those who are so situated. It is therefore a matter for general congratulation that a satisfactory solution of the problem has been arrived at. Those who wish for particulars are invited to fill up and return to the undersigned the subjoined form, when the fullest information will be forthcoming from a source which is highly approved and recommended by THE SANITARY RECORD.

Please inform me what Annual deposit would be required to provide a Pension of £_____ per annum in _____ years, and what sum my family would secure in the event of my decease previously; also any other investment advantages offered on my surviving.

Name _____

Address _____

_____

Age _____ *(nearest Birthday).*

Sanitary Record,

APRIL 29, 1898.

Notes.

Sewage Purification: Manchester Report.

THE Report of a Special Committee of the City Council of Manchester, which was appointed to visit various towns in the kingdom, and to report upon the best method of dealing with the Manchester sewage, is of such a valuable character to all who are interested in the question of sewage disposal, that we propose publishing it in the columns of THE SANITARY RECORD. The deputation visited ten towns, accompanied by the City

Surveyor and City Chemist, and inspected the sewage works for themselves, so that they might form an unbiassed and proper opinion of the merits and demerits of the systems of sewage treatment in operation. They were also furnished with reports as to their cost and general working by the City Surveyor, and also in regard to the chemical side of the subject, by the City Chemist: the result being that a report has been compiled which may rank as one of the ablest and most reliable of its kind dealing with the most recent methods of sewage purification. It may be useful at the present moment to observe that the Sub-Committee state, in concluding their report, that they "agree that of all the methods of artificial filtration that nearest to natural action and most reasonably practicable and available for adoption is the biological filter or bacteria bed, such as may be seen in operation at many of the places visited." The Report will be published in a series of chapters, the first of which will appear next week.

Drug Adulteration.

One of the most difficult Acts of Parliament that Local Authorities have to administer is that dealing with the adulteration of food and other products. In some parts its provisions are so unpopular that it has never been adopted, or if adopted, it has remained practically a "dead letter." Especially does this appear to be the case with regard to drugs. No article lends itself so kindly to adulteration, and it is well known that the opportunities for deception are largely taken advantage of; yet very few prosecutions take place, nor do we think their number is likely to be increased if the decisions given by magistrates are similar to those recently arrived at in Sunderland. Analysis having been made of numerous samples of drugs at the instance of the officers of the Health Department, with the result that several clear cases of adulteration were revealed, summonses were taken out against the various offending parties.

Nominal Fines.

It may be interesting to show the groundwork for the prosecution. In four cases "Gregory's Powder" was found to be prepared with carbonate of magnesia instead of oxide of magnesia, as laid down by the "British Pharmacopœia." In another case, a sample of the same powder contained 17·49 per cent. of carbonate of lime. With regard to this case a singular deliverance was made by the Bench. It patronisingly told the Corporation it "was quite right to take proceedings," and the inference drawn by many is that in the others "right" was not on the side of the Corporation. Further, in two instances, sublimed sulphur was supplied instead of precipitated sulphur; in other two, the same drug being asked for, the packets supplied contained 7·77 per cent., and 62·17 per cent. of hydrated sulphate of lime respectively. The truth of these analyses was not disputed, and it was clearly demonstrated that there was a difference of 50 per cent. in the value of the articles sold and what they were represented to be. But in every case the fine inflicted was only 1s., and that without costs.

Inciting to Adulterate.

If ever there was an instance of inciting tradesmen to commit fraud, we think it is supplied in the cases before us. The whole tone of the magistrate's remarks seem to imply that the summonses were an act of "persecution" on the part of the Health Committee, instead of the carrying out of a public duty. Our surprise at the result is increased by the fact that on the bench was one of the leading practitioners of the town. We wonder what he would say if he prescribed magnesia for a patient and the chemist supplied "carbonate of magnesia" as the genuine article. We learn, also, that the Sale of Food and Drugs Acts have been until lately almost entirely neglected in Sunderland, and the recent decisions are not likely to encourage further action on the part of the members of the Health Committee who are desirous of seeing the Acts properly enforced. In fact, the impression has already got abroad that a chemist "may supply whatever he likes," provided the substance sold is not "rank poison."

Southwark Once Again.

The enlightened Vestry of St. George the Martyr, Southwark, is determined to distinguish itself, and promises ere long to become the exemplar in the metropolis of the axiom "How *not* to do it." It seems an utter impossibility for this Vestry to conduct its affairs in a business-like manner, and we pity the feelings of any intelligent ratepayer, as he reads the reports in the local papers of the undignified proceedings taking place at the regular meetings of the Vestry. This, however, is by the way. But really it is time the attention of the Local Government Board should be drawn to the continual shelving of the complaints and recommendations of the Medical and other Officers. For instance, at the last meeting one of the members directed attention to the unsatisfactory condition of affairs in the crypt of the parish church. Constant complaints were being made that a very unpleasant effluvia arose from this portion of the building, caused no doubt by the decaying bodies deposited therein.

"A Danger to Public Health," but "it's of no consequence!"

Confirmatory evidence was also given by others, the rector stating that more than one member of his congregation had called his attention to the nuisance, especially when the wind was blowing in a particular direction; and he had personally sought the advice of the Medical Officer. The Vestry was asked to refer the complaint to the Public Health Committee; but a representative of that body stated it had already been considered, and it was not thought necessary to take any action. The Vestry endorsed this view. Dr. Waldo, the Medical Officer of Health, wished to make a statement, but was promptly silenced by the chairman. So the stench may continue, children and adults may inhale the poisonous fumes, disease may be disseminated broadcast, but for some occult reason it matters not to these representatives (!!) of the people—"it's of no consequence" to them. If this is the position they take up, then they must be taught that public affairs cannot be allowed to be administered in that slipshod fashion. The Vestry is, or should

be, the guardian of the public health, and if its attention is called to a supposed nuisance, the least it can do is to inquire into the matter and see if there is any foundation for the complaint. But what the Vestry has declined to do to-day it will be compelled to do to-morrow. We respectfully beg to call the attention of the Medical Officers of the Local Government Board to this intolerable nuisance, and urge them to send the Inspector of Burial Grounds to investigate for himself. After such a visit the Vestry may deem it wise not to wait for the report, but order either the blocking up of the crypt or the removal of the human remains to a place where they will be less dangerous to the inhabitants of the district.

Another Public Officer.

Very soon the new Workmen's Compensation Act, passed last session, will come into operation, and with it we have the establishment of a new public office to be held by medical men. An official notice has been issued to the effect that the Home Secretary proposes shortly to proceed to appoint a number of "Medical Referees," whose principal duty will be to act as the advisers in medical matters of the Committees, Arbitrators, and County Court Judges, who are empowered to decide all questions arising in proceedings under the Act. For this duty they will be paid by the Treasury, and a scale of fees has already been approved. The appointments will be made according to the County Court circuits, Referees being appointed for each of the fifty-five Circuits into which England and Wales are divided. The Secretary of State, who has had the advice both of County Court Judges and of high Medical Authorities, deems it essential that the Referees should be men of independent position and high standing in their profession. Other things being equal, preference would therefore be given to those holding important hospital appointments, or having had other special opportunities of gaining wide experience of accidents and their consequences; and to those who are not closely identified, by the nature of their practice or otherwise, with the classes affected by the Act. Applications for the appointments should be addressed to the Home Secretary.

The Vaccination Bill.

The Vaccination Bill came up for second reading in the House of Commons on the 19th inst.; but though Mr. Chaplin urged the House to push through that stage during the sitting, the debate was adjourned. It cannot be said that the discussion threw much new light on the question. The speeches of Sir Walter Forster and Sir William Priestley, however, were of interest, as anything they have to say on a subject like this is always sure to command a respectful hearing. It goes without saying that they were both strongly in favour of the measure, though they subjected it to some criticism in points of detail. The statistics quoted by Sir Walter Forster should have been sufficient to dispel the fixed idea in the minds of the opponents of the Bill as to the extent of the danger attendant on the practice of vaccination. He pointed out that in England and Wales the proportion of deaths traceable to this cause to the total number of vaccinations was one in 14,159, while in Scotland it was only one in 38,872; the low proportion for Scotland being probably due to the age limit there being six months, when the operation can be performed with greater safety.

Domiciliary Vaccination and Vaccinating Stations.

It was fully recognised in the debate that the domiciliary vaccination provided for by the Bill, in accordance with the Scotch system, would prove very beneficial; for among other advantages may be mentioned this one, that it will save the risk of aggregating a large number of children in the vaccination-room, and diminish the chance of septic germs affecting the vaccination. At the same time the hope was expressed that the Local Government Board would not do away with vaccinating stations, under such conditions as might be necessary to prevent infection. Mr. Chaplin accordingly assured the House that stational vaccination would not necessarily be abandoned—it would only cease to be compulsory; and he pointed out that there was nothing in the Bill to prevent Boards of Guardians continuing to make use of stational vaccination, if they found it was preferred, or in the case of persons desiring re-vaccination when there was an epidemic of small-pox.

The Extension of the Age-limit.

It has already been pointed out in these columns that the extension of the age-limit may very probably result in an increase in the number of "unaccounted-for cases." Under the existing state of things about 10 per cent. of the children in Birmingham, for example, escape vaccination owing to removals before they are three months old; and Sir Walter Forster thought that if the age should be extended to twelve months, as proposed by the Bill, the proportion might very possibly reach 50 per cent. Still he believed that the advantages of vaccination at a later age than at present were so great as to justify the extension of the age. But the suggestion was made that it would be well to make the age the same as in Scotland, viz., six months, as there was little reason why there should be a difference in practice in this respect in different parts of the country. Mr. Chaplin, however, defended the age fixed by the Bill, on the ground that in some rural districts the vaccinating stations were only attended half-yearly, and in such cases to make the age six months would practically involve a considerable curtailment of the age-limit. We are not clear that this argument is sufficiently cogent to outweigh the considerations in favour of assimilation of practice, especially as the six months age is advocated by the leading medical authorities. That is the limit favoured by the Incorporated Society of Medical Officers of Health, than whom there can be no more competent judges.

Some Suggested Amendments of the Bill.

The leading points of criticism advanced by Sir William Priestley and Sir Walter Forster are, indeed, all to be found in the resolutions adopted by the Incorporated Society at the conference reported by us last week, and probably

some of them will be brought forward again at the Committee stage and embodied in the measure. One of them relates to the admission of unvaccinated children to school. In Germany, such children have to be vaccinated, and evidence of efficient vaccination must be produced before they will be admitted to a public elementary school, and it is thought that we might, with advantage, adopt a similar precaution. A more important point still relates to the question of administration. Sir William Priestley urged that as the Boards of Guardians had not satisfactorily performed their duties in the past, the administration of the law should be transferred to the Sanitary Authorities. The expediency of this reform, which is also endorsed by the Society of Medical Officers, is so obvious that we wonder that it was not made a leading point of the Government Bill. Perhaps it was on account of anticipated opposition, for though Mr. Chaplin did not refer to the point in his speech, we note that with regard to certain other reforms, which he confessed to be in themselves desirable (such as re-vaccination) he maintained the impracticability of including them in the scope of the Bill if it was to pass into law this session.

The Opposition to the Measure.

Part of Sir William Priestley's speech was devoted to a vindication of the efficacy of vaccination, which he felt to be necessary in view of the prejudiced character of the opposition to the Bill. And yet, if we read the speeches of the opponents, we cannot but be struck with the singular lack of argument shown in them. It was said that "vaccination was wrong in principle and bad in practice;" and also that the decrease of small-pox was rather due to the great change effected by the general public health law, than to the compulsory vaccination of children. But for these statements not a vestige of authority was produced; whereas Sir William Priestley, speaking as an expert, maintained that if any scientific fact was ascertained beyond all reasonable doubt, it was the potency of vaccination to prevent small-pox. He classed the antagonism to vaccination along with the misguided ignorance of those who have opposed sanitary reforms in all times and in all parts of the world, and said that it was a public calamity when such ignorant and factious opposition succeeded in thwarting the teachings of science. It was a weighty indictment, and will not be liked by the anti-vaccinators. We wonder what answer they can make to the hard fact stated by Mr. Monk, member for Gloucester, that during the small-pox epidemic in that town the mortality was only 10 per cent. among vaccinated people, and 40·8 per cent. among those who had not been vaccinated.

The Plague in India.

There has recently been a singular falling off in the telegraphic reports regarding the progress of the plague in India. One might infer from this that "no news is good news," for if the mortality continued to be very alarming, or if the sanitary measures of the Plague Committee were giving rise to a renewal of the popular disturbances, we should be certain to hear about it. And yet we understand that the aspect of affairs in Bombay is still sufficiently grave. The plague is still rampant, and but for strong military precautions the ugly head of riot would again show itself. The white population, too, consider that the Authorities have made far too many concessions to native prejudice—concessions which, while not appeasing the malcontents, have materially increased the risk of the plague spreading from the native quarters to the British part of the town. In striking contrast with these gloomy reports, it gives us pleasure to observe that in Poona the native community have come round to see the real blessings that have attended the efforts of the British to suppress the plague, and have publicly testified their appreciation and gratitude for the success which has attended these efforts.

"Sanitation in the British Mercantile Marine."

The publication of a little book under the above title should direct notice to a subject which, we fear, does not receive, even from sanitarians, the attention that its importance deserves. In the great ocean liners the passengers and the superior officers at least have no reason to complain of lack of attention to their well-being and comfort, but how far can the same be said of the crew? And in the smaller class of trading vessels, the accommodation for the men must often be far too scanty and cramped to be thoroughly healthy. Deficiency in ventilation, and the other sanitary requirements in the sleeping quarters of the crew will not, of course, be felt so much by a seaman, whose life is passed almost entirely in the open, and under the invigorating influences of the sea breezes, but the lot of stokers, firemen, and engineers who are confined during the day to the engine-room and the stokehold, is a harder one. The author of this work, Mr. W. G. Romeril, Sanitary Inspector for the Port of London, speaks from the point of view of a wide personal experience, and an intimate practical knowledge of the subject, and he is able to show that in these respects there is great room for improvement in the sanitation of our ships. The chief sanitary deficiencies—including excessive heat and limited ventilation—exist in the lower quarters of a vessel devoted to the engineers and their subordinates, and the conditions under which they have to work are often productive of nervous exhaustion and other ills, that have a very serious tendency to shorten the lives of the men so engaged. Such conditions are perhaps to a certain extent inseparable from the nature of their work, but there is little doubt that they are capable of amelioration.

Electric lighting, says the *Daily News*, is proving a successful business in the hands of the St. Pancras Vestry. The profit on the last year's working has sufficed not only to wipe out a deficit of £800 on the previous year's accounts but to provide a balance in hand of £5717. This gives electric current consumers a lively expectation of reduction in the price, which for lighting purposes s at present 6d. per Board of Trade unit.

LIME, MORTAR, AND CEMENT: THEIR COMPOSITION AND ANALYSES.

By W. J. DIBDIN, F.I.C., F.C.S., &c.

CHAPTER I.

CHARACTERISTICS OF VARIOUS LIMES.

Chemically speaking, pure lime is an oxide of calcium. It is white, caustic, and soluble in water to the extent of 11 grains in a pint, or 88 grains per gallon. It combines with carbonic acid to form carbonate of lime, which is familiar to us in an impure state in the form of chalk. The metal calcium is never met with in an uncombined state in nature, being always combined with other elements, and chiefly as carbonate. The "atomic" weight of the metal is forty, compared with hydrogen taken as unity. In its pure state it is yellow, harder than lead, ductile, and malleable. It combines with oxygen slowly in dry air, more rapidly in the presence of moisture, and must be preserved out of contact with air. When heated in air to a bright red heat it melts and ignites, burning with a bright white light, and forming the oxide of calcium. It is this calcium oxide which is the pure substance of our inquiry, and, as may be supposed, it is never obtained absolutely pure in commerce—in fact, for the purpose of making mortar and cement it would be but of little use unless it was combined with other materials, such as silica, iron, and alumina.

In the form of carbonate, calcium oxide, or lime, as it is generally known, constitutes some of the most common minerals and rocks, viz., arragonite, calc-spar, chalk, limestone, marble. It is a constituent of dolomite, which is a compound of carbonate of lime and carbonate of magnesia, having the composition $Ca\ Co_3\ Mg\ Co_3$. Lime also occurs in anhydrite ($Ca\ So_4$), and in gypsum, or alabaster, and in selenite ($Ca\ So_4,\ 2\ H_2O$); as fluoride, in fluorspar ($Ca\ F_2$); as phosphate in apatite [$Ca\ F_2,\ 3\ Ca_3\ (PO_4)_2$]; and as silicate it is widely diffused in different minerals. Many of the salts of lime are normal constituents of soils, of plants, and of the animal body; egg shells, coral, and the shells of the mollusca consist chiefly of calcium carbonate, whilst bones consist chiefly of calcium phosphate. The carbonate (held in solution by free carbonic anhydride, better known as carbonic acid) and the sulphate are also normal constituents of natural waters, and causing, with the magnesia and other salts, the property known as hardness.

If a fragment of marble, which is practically pure carbonate of lime, be heated in such a manner that the carbonic acid set free can escape, a white substance will be obtained, which is the oxide of calcium, or quicklime, having the composition, chemically expressed, of CaO, thereby indicating the combination of one atom of calcium with one atom of oxygen, and this compound has an "atomic" weight of 56, being 40 for the calcium and 16 for the oxygen. Its specific gravity is 3·08, water being taken as unity.

This white, amorphous solid attracts water and carbonic acid from the air, and under favourable conditions combines with great energy and much evolution of heat with water, forming calcium hydroxide, $CaO + H_2O = Ca\ H_2\ O_2$. When water is poured upon a mass of quicklime, the latte swells up, cracks, and emits steam, and finally fall into an impalpable powder. The purer and fresher the lime the more rapidly does this phenomenon occur. In this condition the lime is known as "slaked." If an excess of water has not been employed, the powder is to all appearance dry, and is far finer than the unslaked lime can be obtained by any process of grinding. When in the course of time the lime again combines with carbonic acid by absorbing it from the atmosphere, it necessarily parts with the water so taken up, the carbonic acid replacing it, thus $Ca\ H_2\ O_2 + CO_2 = Ca\ CO_3 + H_2O$. This action is the cause of the efflorescence in brickwork known as "saltpetreing," which will be referred to later on. The water thus displaced dissolves other salts, the solution thus formed finding its way to the surface of the work, there evaporates, leaving the crystallised salt as a crust on the surface of the wall. From this observation it will be seen that lime, considered as a chemical substance, is a very definite body, having characteristics peculiar to itself, and that these characteristics are the same wherever the lime may have been obtained. It is when we come to consider the actual properties of the various limes obtained in commerce that certain very specific characters are brought into play, and it is these which we have to consider in relation to the adaptability of the commercial lime for certain uses. Thus the lime most suitable for making mortar is by no means the best for making lime-water in large quantities, or for the purpose of the gas manufacturer in purifying his gas. These differences, it will be seen, are due to certain substances—or impurities, strictly speaking—which affect the quality of the mixture.

The following table of analyses of various limestones, &c., will serve to indicate the differences in character of the raw material before it is converted into lime by being burnt in the kiln. First of all, it is to be noted that the various limestones may be classified under four heads, viz.:—(1) Fat or pure limes; (2) poor limes; (3) hydraulic limes; (4) cements, natural and artificial. As it will be seen, these classes merge gradually into one another, and it is difficult to draw a sharp line of demarcation in many cases, therefore we have "good" and "bad" limes, according to the purpose for which they are intended. Many of these analyses have been confirmed by the writer from time to time, and may be accepted as forming an accurate sequence of results representative of the limes in question.

From this table it will be seen that the hydraulic character of the lime is due to the presence of certain impurities, viz., silica, iron, and alumina, which are included in some of the analyses under the head of "clay"; and that as these increase in quantity up to the extent of about 30 per cent. the "hydraulicity," as it is called, of the lime produced by the burning of the stone is increased.

It will now be seen how important it is that the use to which the lime is to be put should be first considered before a purchase is made. Thus, if the lime is required for use in a gasworks, &c., where the chemical activity of the lime is of the first importance, it should be as pure as possible, and therefore "fat" limes should be obtained. If, on the other hand, the lime is required for mortar making, good hydraulic lime should be

ANALYSES OF VARIOUS LIMESTONES.

Composition stated in Percentages.

Name of limestone.	Carbonate of lime.	Carbonate of magnesia.	Silica.	Iron and alumina.	Water and loss.	Authority.

Arden, Glasgow	68·0	0·8	28·8 clay		2·4	Ingram

purchased. In the case of the manufacture of cement, the quality of the limestone employed must be considered in regard to the quantity of clay to be mixed with it to form the "slurry," from which the cement is manufactured. This point serves to indicate the importance of chemistry in regard to our manufactures. For years the English Medway cements were considered far superior to that of German manufacture, because the ingredients naturally to hand constituted the best materials for the purpose; but as soon as the German manufacturers studied the question from the chemical standpoint they were enabled to so choose their ingredients as to turn out cement equal to the best of the English makes.

It will be understood that when the limestones are burnt the relative proportions of lime, &c., vary by reason of the loss of carbonic acid driven off by the process. Thus, while the marble would show still 100 per cent. of pure lime, there being no impurity present, the white chalk would yield a lime having the composition of:—Lime, 55·2; magnesia, 0·2; silica, &c., 1·0 = 56·4; or, expressed in percentages, lime, 97·9; magnesia, 0·4; silica, &c., 1·7. In like manner the carboniferous limestone, having 86·2 per cent. of carbonate of lime, would, by the loss of carbonic acid, yield only 46·3 of lime to 11·2 of clay, the percentages being:—Lime, 81·2; clay, 18·8. It will be remembered, from what has been stated in the first part of the chapter, that each 100 parts of carbonate of lime yields, if thoroughly burnt, only 56 of lime, by reason of the loss of 44 parts of carbonic acid.

The following table of the result of properly burning all the above limestones will be of interest. In each case it is assumed that the "water and loss" shown in the foregoing table is eliminated.

TO OUR READERS.

The Editor solicits the co-operation of readers in making The Sanitary Record *more attractive by means of pen-and-ink sketches, photographs, and diagrams. There are many phases of sanitary work which lend themselves admirably to illustration. By this means not only individual articles, but the journal as a whole will be brightened.*

THE SANITATION OF DOMESTIC BUILDINGS.

By Frank Latham, C.E., M. San. Inst., &c., Assistant Surveyor, Borough of Margate.

CHAPTER VII.

DRAIN TESTING.

All drains should be specially tested before being covered in, to prove them as being gas and water-tight. The neglect of this important measure is sure to lead to trouble. It is requisite also that these tests should be extended to the soil and ventilation pipes, not only to ascertain if there are any defects in the jointing, but also in the case of the latter as to their due working, as they are liable from some unseen cause to a reverse action, the inlet and outlet having exchanged functions. It is imperative, therefore, that all drains upon completion should be carefully and exhaustively tested, so that their condition may be ascertained without doubt, and in the event of faults in construction or material, they may be exposed and properly rectified.

With respect to drains which pass under, or near to dwelling-houses, the best and safest one is the hydraulic or water test, which is applied in the following manner.—The lowest part of the drain is plugged by the insertion of an india-rubber expansion stopper, such as Jones' (Figs. 86 and 87);

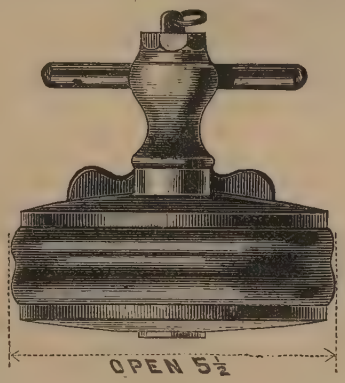

Fig. 86.

and after this has been done, the drain is filled with water until it runs into one of the gully traps at the highest level. Should the drain be perfect, the water will remain for some time at this level without lowering; but if a leakage or weakness exists, the water will either never reach this level, or, should it do so, will immediately begin to subside.

It is needful to remember that upon the drain being filled for the first time a certain quantity of water may be absorbed by the dry materials of the inspection chamber and pipe joints, &c., but the amount of water thus absorbed ought to be only a trifling quantity. Particular attention, however, should be paid to the external condition of the pipes and joints in order to detect any signs of sweating, this sweating proving that the pipes or joints are imperfect and unsuitable for their purpose.

In view of the severity of the water test, especially as regards drains with ordinary cemented joints, these joints should always be permitted to set firmly before the test is applied, otherwise there is the likelihood of the cement being washed out of the joints or otherwise disturbed, which upon setting will render the drain defective.

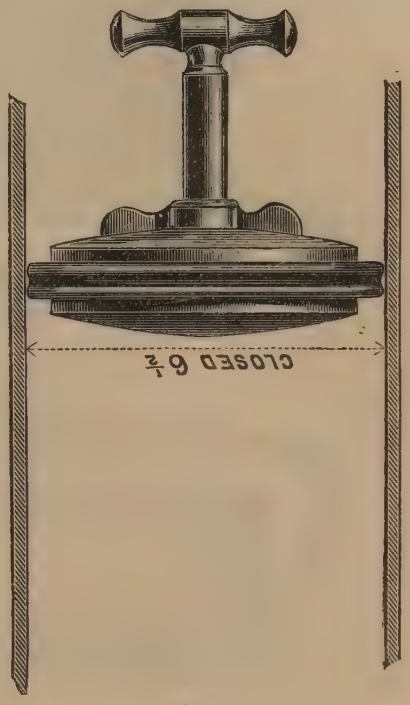

Fig. 87.

Ordinary socketed earthenware drains having a fall of over 5ft. should be tested in sections. The advantage and necessity in such cases of using patent composite jointed stoneware pipes, or iron pipes caulked with lead, will thus be plainly seen, the joints of these being perfect in resisting high pressures, in some instances the pipes having given out before the joints. Soil pipes and ventilators should also be sufficiently substantial to stand the water test, and in the case of the former it is essential that they be so tested. This can be easily and conveniently done by plugging the end of the soil pipe and flushing the water-closet. Where there is a second floor of water-closets using the same soil pipe the lowest closets should be plugged by means of a Jones' patent air stopper (Figs. 88 and 89 on next page).

A quick and fairly efficient test, very useful in most cases, and particularly valuable for old drains, is the smoke test, as the smoke will sometimes rise through the ground in the event of the defects existing in the drains, thus locating the position of the fault. This test is highly useful for correctly ascertaining the working of the ventilation pipes, the character of which is immediately disclosed after the drain has been filled with smoke. In applying the smoke test the open ends of the ventilators must be first closed, and the smoke admitted in a manner which will confine it to the drain. Should there be defects in the drain, or insufficient water seals to the traps, the smoke will make its escape, it being, as a rule, easily detected.

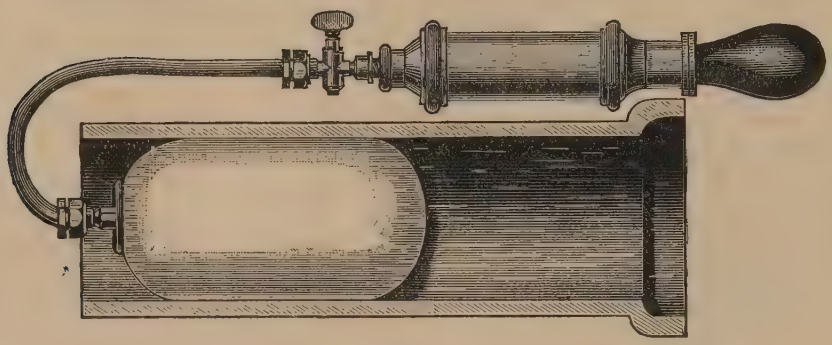

Fig. 89.

"PRACTICAL SMOKE PREVENTION."

By W. Nicholson, Smoke Inspector, Sheffield.

(*Continued from page* 423.)

After having briefly examined the many and various kinds of appliances which have been tried and are working to-day, we are compelled to conclude that much has been done in the shape of inventions to try and solve the question, and we may truthfully say of the manufacturers in general, they have been alive to the importance of the question, and have utilised their experience and tried all sorts of experiments to be able, if possible, to prevent smoke, for which the public is indebted to them. We are now confronted with the question, Is black smoke prevented as far as it is practicable to do so? To such a question we must reply in the negative. How, then, can

PRACTICAL SMOKE PREVENTION

be brought about? We understand by practical prevention, means and methods which will not interfere with the trade work required of the furnace, and the processes carried on therein; methods reasonable in cost, and within the reach of all and within the power of all to perform.

WHAT ARE THESE MEANS AND METHODS?

I. *Common-sense conditions of working.*—(*a*) Sufficient boiler power, and properly set; (*b*) flues large and chimney tall to obtain the desired draught; (*c*) knowledge of power required, and when required; (*d*) the top of the chimney must be seen from the firing hole.

II. *Firemen.*—In the past any man was considered suitable for a fireman if he could use a shovel and was strong in the arm, but now things have changed. All engineers agree that practical firing is an art and requires skill; in other words, the use of the head is needed as well as of hands. It is a very responsible position, because his own life and the lives of others are in his hands. Lack of knowledge, or a little negligence, might prove most disastrous.

(*a*) Teaching or training of firemen is necessary if black smoke is to be practically prevented, and engineers will have to pay more attention to the teaching of firemen.

(*b*) That heat is necessary to obtain complete combustion. Heat can be produced in the best and quickest way by light firing, a little coal on at a time, and firing often. By so doing the fires burn brightly, generate steam quickly, and make little or no black smoke, which prevents a nuisance and produces more steam per pound of coal, which means a slight saving.

(*c*) Side firing: We are all agreed that light firing is the very best kind of firing. There are many ways of firing lightly. Some fire in front, then push it forward when it becomes live coal, others

will work thin fires right across, others a little thicker towards the bridge, and in many other ways are the fires worked; but the one considered the best is the side or alternate firing, and the gases by such a system of firing curl round to the other side of the tubes, where the incandescent or hot fire is which ignites those gases, causing complete combustion. By such a system the fires can be worked thicker, steam generated quicker, and no nuisance in the bargain.

(*d*) The drawback to light side firing is additional labour, and engine tenters and firemen say they have sufficient to do without adding to their work. This is only too true, as I find invariably black smoke is made by the men in charge of the boilers having to leave them to attend to other duties. The fires are neglected, get too low, and black smoke is the result. This can be prevented by the man being constantly in charge of his boilers, and having nothing else to do. They will then have time to fire on the suggested lines, which will be a saving to the masters and a benefit to the public at large.

The above-mentioned suggestions are all essentials for practical smoke prevention, yet there is one thing which is even more essential, and without it black smoke must be made, and that is

AIR.

We must have air to cause combustion of the gases and produce heat. This is beyond question, both in boiler and furnace. It is also admitted that it must be let into the furnaces after a fresh charge of fuel. About that, also, there is no question; but where to admit it there is much difference of opinion existing. Some say the bridge, which is beyond the fire, and others through the door into the fire. Admission of air at the bridge may assert—and experience proves it—that the disadvantages are far in excess of the advantages. Admission of air at the door is almost universal, and expert engineers contend it is absolutely essential, in order to get the best results *re* smoke and economy. The next practical point we are to consider is, shall the air admitted be hot or cold? Many arrangements have been tried, under my own personal inspection, with hot air, and I must candidly confess they have been anything but a success, both in prevention of smoke and evaporation. The fires have burned sluggish, generation of steam has been slow, and the amount of smoke the reader can easily imagine.

I have also seen the effects of cold air, which has been eminently satisfactory when introduced to the furnaces through the doors—smoke instantly cut off, fires burning briskly, and more efficiency all round. It is plain and palpable to all that our furnaces and fireplaces burn better in winter when the air is cold, than in summer when the air is hot. But there are many who stick to the old idea that cold air admitted is very injurious to the boiler. To such we would say, the injury is not real but imaginary, unless too much is admitted; but if only the necessary quantity is put into the furnace, it will improve the working of the furnace rather than injure it.

We must next consider the

QUESTION OF QUANTITY.

It is impossible to lay down a hard-and-fast rule regarding quantity, because there are many considerations—condition of working, coal, draught, and other things—to take into account. The quantity must be decided by the man in charge of the furnaces according to his firings. This is easily done by putting a given quantity of coal on each time, and allowing the number of minutes for admission of air. If that is strictly carried out (as many are doing at the present time), there will be no cause for complaint.

The next important matter is

WHO SHALL ADMIT IT,

man or machine? Either will do; it makes no matter which, because each is able to do it satisfactorily. The latter is often more reliable than the former. I do not want to say one word against the industry and the intention of the men to do all they can to solve this question. I am sure the majority of firemen are most anxious to do everything practicable, but sometimes they forget to admit the air, or they are called away to do something else; then transgression of the law takes place, and penalties follow.

In order to assist the firemen and prevent negligence, simple automatic arrangements in the shape of doors are necessary. The Court has often said (when defendants have made excuses of the kind named), "You must get a machine to assist the men and prevent negligence in the future." If an automatic door is reliable, then its advantages are many. It can be set to let in the proper amount of air, the man can leave his boilers, satisfied it will shut off the air when not necessary, and prevent a nuisance. There are doors which are automatic and otherwise on the market, and it is for steam makers and users of furnaces to select the simplest, most reliable, and best door for themselves.

It is not my intention in these articles to name any apparatus, but place the reader face to face with the facts, which will, I feel confident, enable him to decide which is the very best to meet the public requirements, those of the manufacturer, and those of his men. I have been often asked in Court and out of Court to express an opinion on the merits and demerits of various appliances, but have always resolutely refused, knowing how dangerous it would be to do so, yet at the same time I have informed inquirers what was in the market; also that they were the best judges as to what would suit their special circumstances, and by giving the results of the extensive experiments with apparatuses, such results, I trust, will lead manufacturers to select the system which will practically prevent black smoke.

Heating furnaces, or metallurgical furnaces, other than boiler furnaces.—Papers have been written, lectures given, speeches made, correspondence by the mile in the Press, and reports by Smoke Abatement Associations on smoke prevention, but all have been in reference to smoke from boiler furnaces, and not heating furnaces. They all have with one accord either unintentionally or studiously remained silent on furnaces. We might, from our own practical point of view, when thinking of reasons for such silence, say that most of the writers acted wisely in not attempting to deal with a question on which they had no practical knowledge. Not so with boilers. Though having no practical knowledge of them, they could safely say, with so many others, it has been proved black

smoke ought not to be made by boilers, and very few will contradict them when working them under ordinary conditions. But practical knowledge is absolutely necessary in order to speak with authority on boilers.

When we come to consider heating furnaces, and smoke prevention, a very intimate and extensive acquaintance with the working of them is requisite in order to decide whether any of the black smoke made in these furnaces can be practically prevented.

During the last ten years I have paid very special attention to all kinds of furnaces, and have seen them daily belching forth dense volumes of black smoke in sufficient quantity to turn daylight into darkness. I have visited the works, and by simple experiments (admitting air) the smoke has ceased, with no harm to the furnace; and my experience warrants me in saying that the greater proportion of smoke sent from furnaces can and ought to be prevented. In some cities and boroughs they are compelled to consume, as far as practicable, black smoke in all their furnaces and fireplaces, or, in default, penalties are imposed, while others (by far more numerous) are allowed to pour it out as they like, without any restriction or regulation. What is sauce for the goose ought to be sauce for the gander.

I am fully alive to the difficulties involved in practically preventing smoke from these furnaces and constantly keep in sight the various kinds of work done in them, but in spite of these much can be done. There have been attempts by various patentees to prevent it in furnaces. Some have been fairly successful, while others have been a failure. One system was so successful that, instead of preventing it, it forced it out of the furnace doors, filling the mills, and not going up the chimney; this arrangement had to be very quickly abandoned.

(*To be continued.*)

A YEAR'S PROGRESS IN SANITARY SCIENCE.*

By Joseph Priestley, B.A., M.D., D.P.H., &c.

(Continued from page 424.)

WATER FILTRATION, &c.

As to filtration, the so-called sand filtration is satisfactory, if carefully carried out; but a new method of sand filtration (the installation occupying only one-eighth of the space of an ordinary sand filter) has been brought forward during the year. It has been patented under the name of "the Fischer's System," and consists of vitrefied sand sharp sand, and finely-pulverised glass baked and hardened under very high temperatures, *e.g.*, 1000 deg. to 2000 deg. Fah.) in the form of plates, 40in. square and 8in. thick, with 2in. hollow spaces and 3in. thick walls, placed upright and arranged along the lower portion of the tank. One plate can be cleansed at a time by simply reversing the current of water, whilst the head of water necessary in using this filter is 3ft. or 4ft. Reduction in first cost and in annual working expenses, together with increased efficiency, is claimed for this method of water filtration, which has been chiefly tried on the Continent (Arad in Hungary, Worms, Vienna) Landsberg, Wusterhausen, &c.), but an installation of which can now be seen in England—at Westcott, near Dorking—an installation erected by Messrs. Hughes and Lancaster, of 47, Victoria-street, London.

Dr. Schumberg suggests the sterilisation of water by means of a solution of bromine and bromide of potassium (allowed to act for five minutes), with the addition of a solution of ammonia (9 per cent.) afterwards to remove the bromine—20 parts each of bromine and bromide of potassium in 100 of water being required.

The Pasteur filtration, as carried out on a large practical scale by the municipality of Darjeeling, is proving satisfactory, and will be of value in cases where, from any cause, the water supply of a district is suspected.

As to the metropolitan water supply, the Commission's report of 1893 practically stands good, and consequently for the next few decades London will have to depend upon the rivers Thames and Lee as sources of supply, the present sand filtration being, in the opinion of Government experts, all sufficient to warrant Londoners in resting satisfied. *Nous verrons.* Indeed, the only matter at present troubling the metropolis is as to the advisability or otherwise of its water supply being taken out of the hands of private companies and transferred to those of a trust or public board, the members of which are to be elected by the ratepayers. For the elucidating of this and other kindred matters, a Royal Commission has been allowed by the Government, appointed, and has commenced already its sittings, with instructions to consider as follows:—(1) Should the undertakings of the water companies be acquired and managed by one or more Authorities, and if so, which? or (2) should additional powers of control (and if so, what) be exercised by Local and other Authorities? or (3) whether two or more of the different systems of supply should be connected?

Similar questions are being discussed by other Sanitary Authorities outside the metropolis, and the Maidstone and other epidemics have undoubtedly been, and will be, the cause of many Authorities putting their houses in order in regard at least to water supplies.

Before leaving the subject of water supplies, it may be mentioned that during the last year the Local Government Board has at length given a decision on the subject of Sanitary Authorities engaging the services of so-called water-divining experts, and auditors are in future to be allowed to surcharge Authorities with the costs incurred therewith. The question came up in connection with Mr. Gataker (a water diviner) and the Ampthill Urban Council, and other water diviners and the Porthcawl District Council, &c.

HOUSE REFUSE, &c.

Prominence has been given to the utilisation of household dust and refuse for the generation of electricity by the installation at Shoreditch, London, of large destructor furnaces, which burn the house refuse, &c., of that particular metropolitan district, and from the heat obtained therefrom produce steam for the purposes of driving dynamos and generating electricity for lighting the public streets,

* Abstract of article contributed to the *Medical Annual*, 1898.

&c. The idea is an old one, but its practical application for the electric lighting of a metropolitan parish belongs to the past year, and the eyes of the world are watching the experiment, which, so far, is proving highly successful.

DISINFECTANTS.

Many attempts have been again made during the past year to discredit the time-immemorial method of sulphur disinfection by fumigation—the germicidal value of sulphur fumes being (it is stated) practically a minus quantity. Bacteriological evidence is brought forward to show that certain germs are not, or are at least but slightly, affected by exposure to sulphur fumes, but the practical experience of centuries is made to count for nothing, and the important fact forgotten that in all probability the value of sulphur disinfection depends upon the after-cleansing and ventilation of rooms that is so necessary owing to the tenacity of the smell of the sulphurous acid. Many practical Health Officers can prove that return cases of infection, after sulphur fumigation and due to its inefficiency, are so few, that they may be disregarded—a fact that ought to weigh well with sanitarians before condemning a well-tried friend!

"What method of aërial disinfection, other than by sulphurous acid, is to be used?" is a question that naturally suggests itself, and that has been brought prominently forward lately at congresses, societies, &c. A panacea has, in the opinion of some, been found in the so-called formalin, which, in the form of dry tablets, can be used in, *e.g.*, the Alformant lamp. By means of this lamp it is possible to regulate the precise volume of gaseous formalin required for any room capacity, and for any degree of air sterilisation or disinfection, one tablet being sufficient for the sterilisation of one thousand cubic feet of air, and ten tablets for the effectual disinfection of the same volume. Bacteriological experiments are forthcoming in quantity to show that formalin is a germicide of great value, and withal harmless to man—an important proviso that is being claimed recently for many other new disinfectants as well. This use of formalin as an aërial disinfectant has been tried before, whilst formalin as a food preservative is well known.

The Alformant lamp is the patent of Schering, brought out for the gasification of dry formalin by the Formalin Hygienic Company, Limited, of 9 and 10, St. Mary-at-Hill, London, and consists of a cylindrical mantel heated below by a spirit lamp (with suitable wick), and in the upper part of which is a vessel into which the tablets are placed. The combustion of the methylated alcohol gives off CO_2 and watery vapour, which escape through slits in the upper end of the vessel, and which in their passage take up the formalin vapours given off by the heating of the tablets.

Chemically considered, formalin is a watery solution of 40 per cent. formaldehyde gas—the gas which is given off when the solution is exposed to the air having no deleterious action on wool, silk, cotton, linen, leather, hair, &c., and little (if any) upon colours. It does not attack iron and steel. NH_3 neutralises formalin, forming the compound formamide.

The difficulties hitherto have been to find a method of practically utilising this newly-introduced gaseous disinfectant. Thus, when a commercial (watery) solution of formalin is heated, and the concentration exceeds 40 per cent., a polymerisation of the formalin occurs with a precipitation of paraformaldehyde, which burns, if the heat be continued; whilst a solution of formalin in methyl spirit (called holzin) spatters badly, and large enough quantities of formaldehyde vapour cannot be developed therefrom in a short space of time. Further, the superheating of formaldehyde solutions under pressure of three atmospheres is risky and expensive. These practical difficulties, however, appear to have been surmounted in the form in which this aërial disinfectant is now used, viz., by means of tablets of solid polymerised formalin (or paraform or tryoxymethylin, as it is also called). Each tablet is 15 grains, and may be vaporised by the so-called Alformant lamp.

The alternative method of generating the gas (Trillat's) is by no means of a calcium chloride solution of the gas in an Autoclave. The gas is dissolved in a solution of calcium chloride, and heated under pressure, with the result that practically dry formic aldehyde is evolved, and this does not polymerise. The Autoclave is a container constructed to bear a high pressure, and is provided with a pressure gauge and thermometer. When the pressure gauge shows 40 lb., the gas is evolved and escapes through a fine copper tube, which is generally thrust through the keyhole into the room to be disinfected, the Autoclave (which needs attention) being kept outside.

Whether or not formalin will supplant sulphurous acid as a gaseous disinfectant remains to be seen; and whether or not, should such supplantation take place, the results will be equally satisfactory, is for the future to decide.

As an antiseptic, its use in surgery and medicine may be mentioned—the best form for this purpose being a fine powdered formalin gelatine, known under the name of "Dr. Schleich's glutol." When placed on wounds it forms, in a short time, a firm scab, and the antiseptic is liberated whenever the glutol is acted upon and decomposed by organic and organised ferments.

The testings (bacteriological and chemical) carried out by Dr. Rideal and Mr. Sewell during 1897 go to show that "Okol" (a preparation of the Sanitas Company, *vide* "Medical Annual," 1897, page 617) has antiseptic and germicidal characters of the highest order, though it is non-poisonous to man. Okol is now shown to be an emulsion of an oil, consisting chiefly of acid hydrocarbon derivatives of the benzine series, resulting from the destructive distillation of coal and other carbonaceous matters at a high temperature.

The value of saturated steam as a disinfectant, and its superiority over superheated, was practically admitted by Mr. Washington Lyon (the patentee of the superheated machine) at the Leeds Sanitary Congress, when he stated that all were agreed as to the advantage of the now generally-preferred saturated steam. The principle involved in steam disinfection is well known and universally acknowledged, but during the year Dr. Alvah S. Doty, of New York, in connection with the port work of the city, has introduced what he states is an improved machine, in which he produces a partial vacuum prior to the admission of steam into the chamber by means of steam exhausts, producing a vacuum of 22in. in one minute, *i.e.*, a strong current of steam from the boiler (with 65 lb. to the square inch pressure) passes by the mouth of a pipe com-

municating with the interior of the chamber. There is also provided a fresh-air inlet (1½in. in diameter) connecting the interior of the chamber with the outer air, and furnished with a stop valve. The whole apparatus is enveloped in a non-conducting jacket of magnesia asbestos, which absolutely prevents heat radiation. The principle of these improvements had already been acknowledged, and similar improvements actually already adopted by the patentees and makers of the well-known machines, *e.g.*, Equifex, Washington Lyon, &c.

Current steam (with and without pressure) is preferred by some, and Drs. Délépine and Thresh have been working out machines on this principle. Where the pressure is slight, the temperature is unfortunately but little above 212 deg. Fah., but the expenses of such a machine are considerably lessened; the machine can, in fact, if required, be made in a portable form, enabling the disinfecting apparatus to be brought to the infected houses, and the necessary disinfection carried out there, but care must be taken before an authority discards the use of high-pressure steam.

In connection with disinfectants, Dr. Rideal has made during the past year a series of important experiments as to the value (if any) of the so-called medicated or disinfectant soaps. The practical outcome of the experiments is that many of the so-called antiseptic soaps belie their names—the antiseptic being destroyed or rendered inert by chemical combination with the basis of the soap used, &c. As a corollary, the fact is forced upon us that after all plain soap and water is the best disinfectant, and cleanliness the sole sanitary requirement.

Fleming's disinfectants—the so-called camphylene—are made in the solid, liquid, and powder forms, and are non-poisonous, non-corrosive, and non-staining. The active principle is evaporated continuously at ordinary temperatures when exposed to the air, and the disinfectant is therefore used as a tablet for hanging in rooms, on the person, or (in the form of moth papers) amongst clothes. The preparation that is most recommended is the camphylene cream—a fluid disinfectant of great strength, yet agreeable in odour. It possesses, of course, all the properties and advantages of camphylene as to its non-poisonous, non-corrosive, and non-staining properties, and is made sometimes mixed with ammonia.

At Barking Creek Outfall Works, says the London correspondent of an important provincial daily, there has been in progress for five years an experiment which every Town and District Councillor in the country ought to look into. It is a one-acre filter bed, devised by Mr. W. J. Dibdin, for purifying one million gallons per diem of effluent produced after precipitation of London sewage. The filtering material consists of 3ft. of coke breeze covered with 3in. of gravel. The process is to pass in first small quantities of effluent so as to gradually develope colonies of the sewage-destroying bacteria. By adopting the eight-hours a-day-system, with a complete rest on Sundays, seven million gallons a week are converted into a clean and sweet filtrate, in which fish live and swim up to the very mouth of the outlet.

SOME EXAMPLES OF SCAMPED DRAINAGE.

By Dr. W. L. Hunter, M.A., M.O.H., Pudsey.

There are yet some builders who, from ignorance, carelessness, greed, or contrariness, would, if allowed to have their own way, execute work discreditable to themselves, dangerous to the health of

Fig. 1.—Choked Drain Pipes from £25 House.

the occupants of the houses, and almost sure to be a future expense, sooner or later, to the owners. The interference of the Inspector in his efforts to secure honest work is very much resented by this

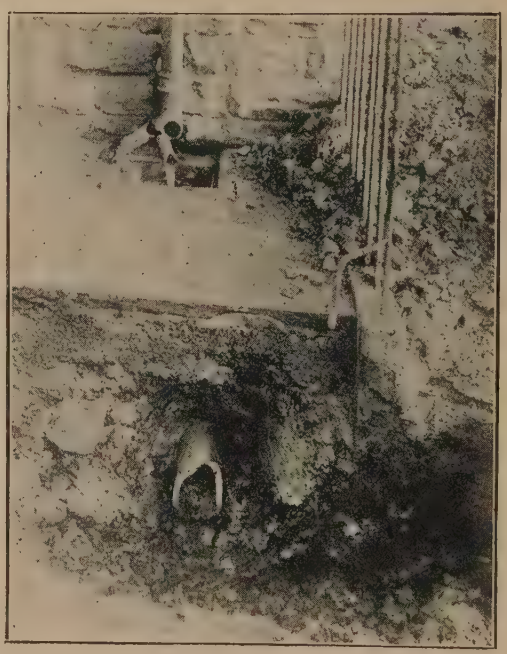

Fig. 2.—Kitchen Sink Waste-water Flowing into House Foundation.

class of builders, and they sometimes pose as martyrs suffering from the despotism of the Sanitary Authority. They, metaphorically speaking, moan, groan, and tear their hair, saying that they will be ruined, and that the progress of the district

will come to a standstill. They as much as say that it is not possible for a builder to make a living if he is not permitted to do "shoddy" or dishonest work. Incredible as it may seem, there are people —otherwise apparently level headed—who are simple enough to believe in these vapourings and

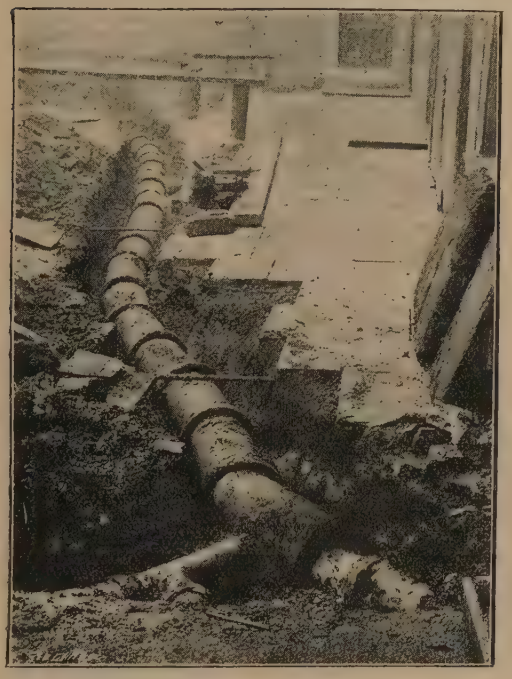

Fig. 3.—Drainage of Two £35 Houses.

who assert that it is a shame to interfere with scamped work.

There are certain well-established principles which should be insisted upon in every case; if they are departed from the result will not be satisfactory. People who are laying drains often protest that they are asked to do more than is needful, and for that reason officials have had to ask for their Council's support in order to get the work done properly. The materials of all drains should be of the best quality and pattern. Drains should be laid on straight lines and with a regular fall. There should be laid a solid foundation, and not too close to the surface. They should be properly disconnected from the sewer, and ventilated. They should be made accessible for the purposes of inspection and cleaning out. No drain that does not satisfy all these requirements should be "passed" as being satisfactory. Almost every week nuisances come to our notice that are caused by systems of drainage in which these essentials were neglected. I reproduce some recent photographs which illustrate a few of them.

Fig. 1 shows three completely choked 6in. drain pipes—the one next the gully and the two following —which took the kitchen sink waste water from a £25 house. The drainage was laid down about ten years ago. The entire drain from the house to the sewer was 30ft. long. The line of drainage was irregular; there was no provision for inspection or cleaning out. The occupier of the house did not know that the drains were choked. The drainage of the house next door was similarly choked. It is interesting to note that the gully was in a clean concreted back yard.

Fig. 2 shows the drain cut across, of a nearly new cottage house. It also shows the water which was kept running from the kitchen sink into the gully for five minutes, not a drop came through the opened drain, and therefore all the waste-water sewage must have flowed into the house foundations. There was no inspection chamber by which to discover that the drain was not acting properly.

Fig. 3 reproduces the drainage of two £35 houses showing a number of obvious defects.

In Fig. 4 we have the junction of the drain of eight back-to-back houses. (*a*) Main drain from the four houses at the back, coming under one of the front houses. (*b*) Drain from sink pipe of one of the front houses on right side. (*c*) Drain from the other front houses on right side. (*d*) Joint drain from the other two houses in front on the left side. (*e*) Main drain leading to the sewer.

The above photographs are selected from a large number which show equally glaring effects. In every case the present owner of the property had been put to considerable expense and annoyance,

Fig. 4.—Junction of the Drains of Eight Back-to-back Houses.

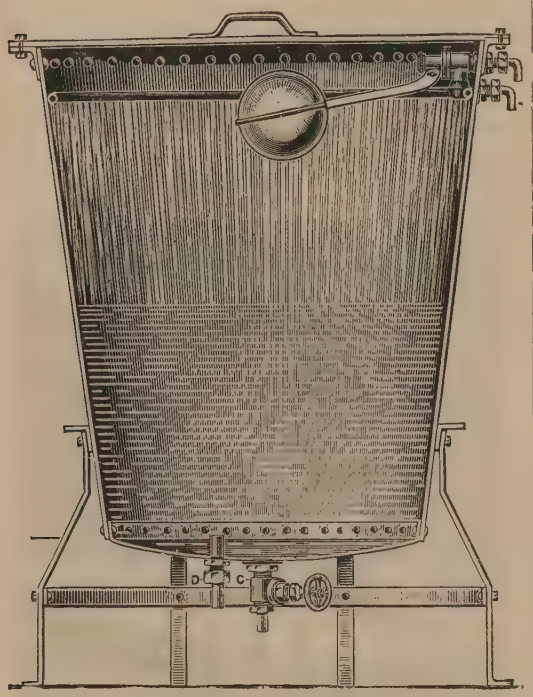
the result of former unskilful or careless work. In many cases injury to health was caused. Had the work been efficiently done at first all this would have been prevented. The moral is evident.

EAST GRINSTEAD.—A Local Government Board inquiry has been held respecting the application of the Urban Council for sanction to borrow £540 for rebuilding Hurley Bridge, widening College-lane, and the provision of public urinals in London-road and Cantelupe-road.

NEW FORM OF HOUSE CISTERN.

ANY improvements upon the existing type of house cistern are to be welcomed, more especially when they are of such a nature as to possess distinctive merits from a hygienic standpoint. Our attention has recently been directed to Durrans' "Kallio" self-cleansing galvanised iron cistern, which appears, *primâ facie*, to bear out these conditions, and concerning which, we think, a few details would be acceptable.

The question of drinking cisterns and how to ensure their cleanliness, is an ever-recurring topic with those who have the safeguarding of the public health in their hands, and the invention in question, for which we are indebted to Mr. T. Durrans,



Durrans' "Kallio" Self-cleansing Galvanised Iron Cistern.

A.R.I.B.A., architect, will, we believe, justify every consideration from those who are interested in this most important phase of sanitation.

As will be seen from the accompanying illustration, the tank is circular in shape, with conoid sides and bottom, and mounted on an iron-framed stand for easy access to a clear-way emptying valve. The ball valve has a tinned copper circular flushing pipe, so that when the valve is opened all dirt and sediment is completely washed away in a few moments. For convenience where cisterns are fixed inside roofs and in other inaccessible places, the valve (C) can be fixed anywhere with a length of pipe to discharge over a sink below, or in the bath-room; by this arrangement the valve can be turned on and off at will without the slightest trouble most effectually, and thoroughly cleansing the cistern also of sand, which is arrested from the water in settling. D is the union, with connecting piece standing up 3in. from the bottom of the cistern, for the supply of pure drinking water, and the bottom valve at the top is the union for overflow. The cistern is fitted with a galvanised iron cover, bolted down air-tight with nuts and screws to prevent any foul air contaminating the water.

Among the institutions in which the cistern is at present in use may be mentioned Sinhala restaurants, London; Maida Vale and Hall-road Buildings, Avenue Estate Buildings, Ealing; Pine-apple Nursery Estate, and Improvement Dwellings, Hall-road and Acacia-road; and we are assured that in every instance it is giving the highest possible satisfaction.

THE VENTILATION OF SEWERS.

By Dr. MEREDITH YOUNG, M.O.H., Crewe.

THERE appear to be several factors combining to produce the emission of foul gases from a sewer. In the first place, the majority of manhole covers which are supposed to act as ventilators do not act in this way at all, for the holes in them speedily become closed with dirt. In the manholes themselves there are often to be found branch drains delivering into the manhole at such a height above the invert as to cause considerable splashing and spraying of the sewage, and in consequence of this a diffusion of sewer gas. Again, in a large number of manholes heavy road detritus accumulates, and to this accumulation, unless it be swept away, organic matter clings, decomposes, and gives off offensive gases. In a flat district like this it is a matter of extreme difficulty to secure such a fall as will render the sewers self-cleansing, and this adds to the difficulty.

I am of opinion that this nuisance can only be satisfactorily dealt with by the adoption of the two following recommendations:—

First, that in streets where sewer gas makes its presence manifest, ventilating shafts should be inserted on the line of sewer as nearly as possible midway between two manholes, which manholes should not be closed up but left open. In this way the vertical shaft will act as an outlet, and the manholes as inlet ventilators. The shaft should be circular in order to lessen the loss of current by friction, and should have a sectional area of at least 28in., *i.e.*, should be a 6in. pipe. It is unnecessary to point out, of course, that the joints of such a pipe should be absolutely air-tight, and that it should discharge in a safe position away from windows and chimneys.

Second, adequate means of flushing sewers must be provided, the most convenient means, in my opinion, being underground tanks with automatic syphon flushes, or automatic flushing tippers, each of these to be of a capacity of about a hundred gallons. The experience of most engineers shows that flushing by means of flushing valves, that is by back-pounding the sewage, is not a method to be recommended. Whilst the sewage is accumulating deposit is bound to take place, and this deposit may not be altogether flushed away when the sewage is allowed to run off. The sides of the sewers are always left in a dirty condition, and the deposit on the sides may decompose and give off offensive gases into the sewer, or may dry, and any specific infective matter in the sewage is thus afforded an opportunity of getting into the sewer air, disease germs, when they exist in sewer air, most probably

originating in this way. In addition to these objections there is always danger that the pressure on the walls of the sewer or its branches, especially at joints, is likely to lead to damage to the sewer or to escape of sewage into the surrounding soil.

It must be clearly understood that the two things recommended above are recommended to be used in conjunction with each other, and not separately. It has been suggested that if householders were to flush their house drains at a certain hour on certain days in the week, and if a number of householders would co-operate in the matter, a simple and most effective means of flushing would be obtained. It is very much to be doubted whether any scheme of this kind could be made practicable. In sanitary matters the general public usually want helping, and are not eager to help themselves.

THE TREATMENT OF DAMP WALLS.

Dr. E. Vallin, of the French Academy of Medicine, recently read a very interesting and original paper on the "Presence of Saltpetre in the Walls of Inhabited Houses." This he described as a disease of the walls due to the presence of micro-organisms. As the walls could not suffer without causing serious inconvenience to the persons whom they were destined to shelter, it was the duty of sanitary reformers to seek to cure the walls and thus save the inhabitants of the houses. The disease was caused by the penetration into the body of the walls of the bacilli of nitrification, and consequently the houses became cold, damp, and unwholesome. This state was likely to occur in damp localities, and in the presence of nitrogenous organic matter. From the sanitary point of view this disease of the walls could and should be prevented or cured as we prevent or cure virulent diseases among men and animals. Consequently, Dr. Vallin proceeded to speak of the walls of a house just as if they were human beings, and went systematically through the various symptoms of their diseases. Dealing first with the prophylaxis of wall diseases, he pointed out that the primary step to be taken was to thoroughly drain the ground round the walls and isolate them from the surrounding earth, if possible by a trench and by the use of cement, asphalt, or coal tar. Thus the access of water bearing nitrifying bacteria that are aërobic would be prevented.

It was also very necessary to mix the mortar used with antiseptic solutions, such as dissolved sulphate of copper, &c. Where these precautions had not been taken and the disease had broken out, then the treatment indicated was as follows:—First, to scrape off and wash away all superficial traces of saltpetre, &c.; then the walls should be inoculated with active cultures of the anti-nitrifying baccilli which impoverish farm manure by decomposing the nitrates and by throwing off in the atmosphere a great part of the nitrogen which they contain; these walls should then be covered over with impermeable paint so as to retard the process of nitrification of the aërobic germs and, on the other hand, to stimulate the growth of the anaërobic and anti-nitrifying germs which remove the oxygen from the nitrates and from ammonia when they cannot supply themselves with oxygen from the atmosphere. This ingenious theory was highly appreciated and formed the subject of many conversations among members of the Congress. The idea of applying the principles of inoculation to the preservation of material used in building opens out a vast field of possible progress in the domains of sanitary engineering and architecture.

SANITATION AND THE FINE ARTS.

In connection with the Royal Society of British Artists, Sir Wyke Bayliss (president) gave an address in the large gallery of the Society, mainly upon the duties of the dwellers in great cities in respect to the nurture of the Fine Arts. The address was, somewhat enigmatically, entitled "Art in the House of her Friends." Having suggested, in explanation of this title, that if art had any friends anywhere, they were to be found amongst the dwellers in great cities, the president pointed to the connection between the work of the artist and the work of the sanitary engineer. What, he asked, was art but the science of beauty, and what was sanitation but the science of health? Health and beauty were almost synonyms. Where there was perfect health there was beauty, and where there was perfect beauty there was health. If

HEALTH WAS THE FOUNDATION

of the Temple of Beauty, beauty was the shrine in the Temple of Health. Unfortunately, this intimate relation between health and beauty was not popularly understood. It was not, for instance, realised that the advance of architecture was seriously hindered by the insanitary condition of our great cities. Dirt stopped the way of all the splendid developments of decoration, by virtue of which architecture took rank amongst the Fine Arts. He asked his audience to think what the *façade* of a public building might be, but for the all-pervading, ever-increasing, plague of atmospheric dirt. They need not go back in imagination to the times when their forefathers saw the splendours of Westminster Abbey, its delicate tracery, its shafts of marble, its wealth of statuary, long since lost to them in the veil of black slime that covered everything in London. Cathedrals in purer air—Lincoln, Winchester, Ely, or Salisbury—still showed what magic could be wrought by the wizards they called architects. But in London the air was thick with smoke. People passed and repassed, and knew not that the grimy objects that filled the niches of the Abbey were amongst the

LOVELIEST OF THE SCULPTURES

that the world had ever seen. This showed how much we lost of the work accomplished by the great architects of the past. But the limitation on the efforts to create new forms of beauty by the introduction of colour was also to be considered. The resources of the lapidary and of the worker in mosaic were lost to their architects because of the foulness of their atmosphere—a foulness not inherent to it, but made by the populace in the innocent process of cooking their mutton chops. He readily admitted that London must have its mutton chops, and that they must be cooked; but he submitted that they were cooked at too heavy a cost, if the cooking of them was for ever to debar architects from the use of polished marbles, mosaics, and delicate bas-reliefs. The fault was not to be charged to their climate. Milan was

amidst the plains of Lombardy ; Rome was within reach of the miasmas of the Campagna ; Genoa, Pisa, and Venice were wet with the salt mists of the sea. No, it was not the climate they in London had to fight against, but the climate plus dirt.

IT WAS THE CLIMATE

in unholy alliance with the guerilla contingents of smoke and foul gases that decimated their forces, and carried foolishness into the councils of their building committees. He asked were they ever going to clarify the air of London, and Liverpool, and Manchester, and the other dark places of the earth. If it was true of the dark places of the earth that they were full of the habitations of cruelty, it was also true that they were full of the habitations of ugliness. Were they going to give the artist that which he valued as his life—that without which life itself was of no use to him—light? If they would enable the artist to "see" their great cities, he could promise that art would make them beautiful to look upon. Passing from the subject of their enemy, the chimney, the President glanced at the importance of the gutter as an aid to the cleanliness of streets and buildings, and incidentally pointed out that the appliances necessary for the sanitation of buildings were not irreconcilable with the laws of beauty. The

AIMS OF THE SANITARY ENGINEER

fell in with the aims of the architect ; the gargoyle, primarily a gutter, was often shaped to add beauty to the fabric. The gargoyle was essentially the work of the architect, but it introduced the sculptor into the game. The reference to the sculptor brought the President to another branch of his subject. What, he asked, had become of the few works of sculpture that were supposed to adorn London? Did they not look as if they had suffered martyrdom at the hands of the gamins of the streets on the 5th of November? They were absolutely black with slime. Was that the best thing that could be done with them? If they were to be treated as guys, why should they not be made as guys? The sculptor cried for help. Who would save him and his work from destruction? The President next alluded to the effects of the "tenebrous pall" of their cities on painting. Any great scheme for the development of national and historic painting in England was hopeless so long as the present state of things continued. England had taken a high position in the history of art. There had been

TWO GREAT PERIODS OF ART,

the classic, which gave them the Parthenon, and the Gothic, which gave them Westminster Abbey. The mastery in these two schools, each perfect in itself, and neither second to the other, belonged to the people of Greece and to the people of England. The race of men who built their cathedrals were equal in artistic capacity to the race of men who built the Acropolis of Athens. They, then, as Englishmen, had a past to build upon, and ought to have a hope for the future. A pressing question, however, was, as he had shown, the establishment of right conditions. This was a question which the nation must answer through the medium of the sanitary reformer. He was confident that if this question were rightly answered, art would make the nation a rich return. After all was said and done, art was, and always must be, one of the environments of their lives, perpetually shaping them to fair or foul issues. Bad art meant much more than bad artists. It meant dreary surroundings in their dwellings, ignoble buildings in their streets, evil thoughts in their hearts. The converse of this, however, was true as regarded good art, and he earnestly appealed to his hearers to do all they could to assist in the removal of the obstacles which he had indicated as existing in the path of the artist, who should aspire to do noble and imperishable work.

THE SANITARY INSTITUTE.

LOCAL ARRANGEMENTS FOR THE BIRMINGHAM CONGRESS.

A MEETING of the Local General Committee appointed to make arrangements for the annual Congress of the Sanitary Institute to be held in Birmingham in September next was held last week. The Lord Mayor (Councillor Beale) presided, and among those present were Alderman Cook, Alderman Pollack, Councillor Lancaster, Councillor Martineau, Councillor Godlee, Lieutenant-General Phelps, Dr. A. Hill, Dr. Bostock Hill, Messrs. White Wallis, W. Bayley Marshall, J. E. Wilcox, W. Harris, A. Harris, Jordan Lloyd, D. J. Kauffmann, T. Ryland, E. Bliss, J. S. Nettlefold, G. H. Fosbroke, T. R. Bayliss, W. Henman, V. G. Milward, W. A. Hetherington, T. Price, G. C. Vaudrey, J. I. Eagres, W. F. Marston, D. Rose, W. S. Pritchett, &c.

The LORD MAYOR, in proposing the appointment of a large Executive Committee, with his lordship as chairman and Alderman Cook as vice-chairman, said that upon the sub-committees to be formed from that Executive Committee would devolve the work of making the general arrangements for the Congress, and when those arrangements were sufficiently advanced the Committee would be called together to receive the reports. In response to the appeal for funds, guarantees had been received from 230 gentlemen, but he did not think that number was very large, considering the size of the General Committee. He hoped the number would be considerably increased, so that it might only be necessary to call up a portion of the amount guaranteed. The difficulties in sanitary matters were never greater than they were at the present time, and they would probably be enlarged as the population increased. Every member of the Committee was interested in the important topics that would be discussed by the Congress, and he was convinced everyone would do his utmost to make the gathering a success.

The Executive Committee was appointed ; and the following sub-committees were also formed :—Finance (chairman, Councillor Johnstone), Reception and Hospitality (chairman, Councillor Godlee), Excursions (chairman, Councillor Lancaster), Literary and Press (chairman, Alderman Cook), Exhibition (Councillor Bisseker). The following gentlemen were appointed the local hon. secretaries of conferences and sections :—Conferences : Municipal representatives, Councillor J. H. Lloyd and Mr. E. V. Hiley ; Medical Officers of Health, Dr. Barwise and Mr. F. M. Bloomer ; Municipal and County Engineers, Mr. H. Ashton Hill and

Mr. A. D. Greatorex; Sanitary Inspectors, Mr. J. Parker and Mr. N. Deeks; Domestic Hygiene, Mrs. C. J. Bracey, Miss M. Jenkyn Brown, and Mrs. Sargant. Sections: Sanitary and Preventive Medicine, Dr. H. Manley and Dr. T. S. Short; Engineering and Architecture, Mr. H. T. Buckland and Mr. S. R. Lowcock; Chemistry, Meteorology, and Geology, Professor Frankland and Professor Kauffmann. Mr. W. S. Pritchett was appointed the local secretary.

Alderman COOK, in proposing a vote of thanks to the Lord Mayor for presiding, expressed the pleasure everyone felt at the personal interest taken in the Congress by the Lady Mayoress, who would be the president of the conference on domestic hygiene. While the Health Committee were fully occupied with general questions on sanitation, their attention had of late been particularly directed to the cleansing of the courts, but they felt that that alone was insufficient, and desired, if possible, to carry the reforming influence inside the houses. He thought that result would probably be best achieved with the assistance of the ladies, and the conference over which the Lady Mayoress would preside would direct special attention to that subject. The resolution was adopted, and the meeting closed.

A meeting of the Executive Committee was subsequently held under the presidency of the Lord Mayor, who reported that Sir Joseph Fayrer, Bart., K.C.S.I., M.D., LL.D., F.R.S., had accepted the office of president of the Congress. The officers were requested to nominate a list of vice-presidents, and the sub-committees, in conference with the officers, were authorised to make the preliminary arrangements for the Congress and report to the Committee.

THE NATIONAL REGISTRATION OF PLUMBERS.

MEETING AT ABERDEEN.

DR. MATTHEW HAY, Medical Officer of Health for Aberdeen, presided at the annual meeting of the District Council for the counties of Aberdeen, Kincardine, and Banff, which was recently held at the Gordons College, Aberdeen. The chairman, in moving the adoption of the report, said that last year had been characterised by as much vigour in the movement as any previous year, if they had regard to what had gone on all round the country. The two most notable events of the year no doubt were the submission of the Plumbers' Registration Bill in Parliament, and the preparation of the model regulations and bye-laws for the drainage and plumbing work of buildings. The Bill more nearly reached the point of passing than ever it did before, coming to the third reading, when it was "talked out" on account of some slightly factious opposition. That gave them, however, great reason to believe that the Bill that had been introduced this session—a new measure with many fresh features—was one likely to commend general support and become law, unless the pressure of foreign affairs prevented home business being attended to in a satisfactory way. A careful perusal of the Bill led him to think it was likely to conciliate previous opponents, and if it did pass, the registration movement would be put upon an entirely different and a very much better footing. He then pointed to the advantages to be derived by journeymen becoming registered before the Bill passed, and mentioned that at present they had several young men applying to be examined. It was gratifying to know that the class for instruction in plumbers' work still continued to be largely attended. It was almost unprecedented that there should be so many as forty-one young plumbers in attendance. When one considered that year after year for the last ten years there had been almost equally large numbers in attendance, it showed that a large amount of interest was being taken in the classes. The next Congress would be held in Glasgow in August, and as the people there had all along taken a very enthusiastic interest in the registration movement, the gathering was likely to prove very successful.

Mr. A. B. ROBERTSON seconded the adoption of the report, which was agreed to.

Mr. KENNETH CAMERON, Sanitary Inspector of Aberdeen, moved:—"That this meeting, believing that the registration of plumbers under parliamentary sanction would greatly promote the public health by helping to ensure sound plumbing and drainage, and that the voluntary system at present in force, although accomplishing much good, does not adequately meet the purpose in view, resolves to cordially support the Plumbers' Registration Bill at present before Parliament, subject to such suggestions, if any, for its improvement which the District Council may make, and instructs the Council to use its utmost endeavours to aid the passage of the Bill through Parliament." Mr. Cameron mentioned one or two of the provisions of the Bill, and urged all men not at present registered to join before the Bill becomes law.

Mr. J. F. ANDERSON seconded, saying that not only would the whole trade be in a much better position if the Bill passed, but the public even more so.

Mr. R. G. WILSON, architect, proposed:—"That this meeting being of opinion that the model regulations and bye-laws for the drainage and plumbing work of buildings prepared by a Committee of the six District Councils of the National Registration of Plumbers in Scotland, and recently published by authority of the Councils in congress, provide a reliable and well-considered code of regulations for such work, resolves that it is desirable in the interests of the public health that such regulations should be adopted and put into operation by all Municipal and Rural Authorities within this district as soon as may be practicable." They had bye-laws of their own, he said, for some time in Aberdeen, and were working smoothly under them; but it was different when they went outside the city. They had nothing there to guide them, and he hoped some uniform system such as this would be adopted throughout Scotland. It represented the wisdom of the District Councils composed of men well qualified to draw up such regulations.

Mr. W. GARDEN seconded.

The PRESIDENT emphasised the absolute impartiality with which the bye-laws had been drawn up by those engaged in sanitary work in the interests solely of public health. He knew of no better code; and he was aware that the Local Government Board was carefully considering the question of such bye-laws with the view of helping Rural Authorities in adopting a code. He hoped that although Aberdeen

was one of the four cities exempted from the operation of the Burgh Police Act, it might in some future local Act obtain power to make such bye-laws and enforce them directly, for though a similar code was in operation at present, it could not be enforced directly by the Dean of Guilds Committee.

The motion was agreed to, and the proceedings terminated.

Annotations from Annual Reports.

Soil Temperature as a Factor in Diarrhœa Outbreaks.—Dr. T. Ridley Bailey, M.D., M.O.H., Bilston, points out how it is that a certain soil temperature has an important bearing on this disease. The temperature of the atmosphere itself plays no part in the causation of an epidemic of diarrhœa except its slight influence on the range of the subsoil temperature. Thus Baldwin Latham has shown that at Croydon the average temperature of the air in the summer months of one year was 59·4, and for the same months of the succeeding year 61·1, yet the deaths in the former year from diarrhœa were more than five times as many as in the latter. The reason, apparently, is due to the differences in the level of the subsoil water. The moist soil will not heat as quickly as if it were comparatively dry, and therefore in a dry season a less atmospheric temperature is sufficient to bring the soil temperature to that point which is necessary for the development of the germ of the disease. Therefore, the observation that diarrhœa is more likely to be prevalent when the subsoil water is low is probably correct, and is in harmony with the view that "whatever the air temperature may be, diarrhœa does not appear in epidemic form until a definite temperature is reached at a given depth below the surface of the soil." It will be obvious how essential it is that saturation of the ground, particularly near to human dwellings, from deficient or absent spouting, surface water, by leakages from ashpits, cesspools, &c., should be avoided.

Typhoid on Farms.—Dr. R. W. D. Macmartin Cameron, Medical Officer of Health for the counties of Kirkcudbright and Wigtown, in his annual report, gives an interesting example of how typhoid may be generated on farms. "A farm, say, is supplied from a spring of excellent water situated in a field under permanent pasture, and the water is led through the land in ordinary field tiles. So far so good. But some fine day Agricola conceives the idea of ploughing the field (perhaps he is a new tenant and doesn't know better), and plough it he does up to the very edge of the spring, and manures it plentifully. The oats are sprouting nicely, or in the following year more probably the potatoes have just begun to show their pretty blossoms, pink and white, when the cotman is seized with typhoid fever, and the master grumbles at being deprived of a milker in the person of the sick man's wife. Next, perhaps a servant girl in the farm house is 'took bad,' and the farmer, quick to perceive the advantages of hospital isolation where a servant is concerned, makes prompt demand for her removal. The water meantime has been analysed and condemned, and a 'notice' duly served upon the landlord. But not until the farmer's own children fall ill, or he begins *in propriâ personâ* to feel that somehow his 'Bladenoch' or 'Long John' has ceased to do him quite the same amount of good as formerly, is he thoroughly aroused to the danger of the situation. Mighty then his wrath, and boundless his indignation at any delay in providing him with a new water supply in lieu of that he has himself ruined with his midden and his plough. This form of water pollution, I am satisfied, is one of the commonest causes of typhoid fever in agricultural districts. Excuse for it there is none."

Advantages of Public Abattoirs.—Dr. J. H. Barrett, M.O.H., Cheltenham, is a strong advocate of public abattoirs, concerning which he writes as follows in his annual report for 1897:—"The great advantage to the public of having all animals intended for human food killed at a public abattoir must be apparent to everyone who troubles himself to think upon the subject. Not only would it lead to the abolition of the numerous private places used for the purpose, and so improve the conditions of the localities where they are situated, from the point of view of general sanitation, but what is quite as important, if not more so, the centralisation of this business would allow of the ready inspection of all animals intended to be slaughtered, as well as of the meat as prepared for sale, and the foisting upon the public of the flesh of diseased animals at the usual price of sound meat would be prevented. Our own public abattoir has proved an undoubted advantage in these respects, and it is a matter of regret that its use should be limited to a portion only of the butchers of the town. The butchers consider their own immediate interests before all else, and do the best they can to guard them. In this they do not differ from other sections of humanity. Thus they are unwilling to forego the little conveniences attaching to slaughter-houses in proximity to their shops, which they can use at any time of day or night, and go instead to a public abattoir situated half a mile away, where all they do will be under surveillance and criticism. It is futile to expect them to do this of their own free will, and the process of compulsion under such legal powers as have ever yet been obtained is a difficult and costly one. Right, as established by usage in regard to the use of private registered slaughter-houses, is recognised by the law, and has to be bought out, a matter which would appear to result in interminable negotiations, and which cannot always be carried to a successful issue without awakening animosity in the minds of interested parties. The general law upon the subject is weak and unsatisfactory alike for both the governing Corporation and the butchers, and the whole question of slaughter-houses and meat inspection will not be satisfactorily settled without some amendment of the general law."

Water Supplies to Vessels.—The provision of a pure water supply on board ship is a matter of such paramount importance, writes Dr. J. E. O'Connor, M.O.H., Lowestoft, as to demand the most serious consideration by all Port Sanitary Authorities. The disastrous results of a specifically polluted public water supply have been tragically illustrated in this

country during the past year, but nothing can be more terrible than the outbreak of an infectious disease on board a ship, whose crew is compelled to drink a water containing the *materies morbi* itself. Every available precaution ought therefore to be seized upon with avidity, in order to prevent the possibility of such a calamity. Our present system of watering ships from large storage tanks I must unhesitatingly condemn. These tanks are cleaned at irregular and infrequent intervals, and must of necessity contain a large amount of sediment. I advise that their use be discontinued, and that ships should receive their water directly from the mains. A matter of equal or greater importance is, however, the provision for water storage on board ship, and I feel it my duty to report that the wooden casks which are used for this purpose on many Lowestoft fishing boats should be abolished. The alternate wetting and drying of the inner surface of these casks induces decomposition, and this is favoured by want of light and ventilation. Further, any organic sediment that the water may contain is deposited and becomes intimately incorporated with the inner surface of the wood. Water tanks on board ships should be constructed of iron, coated inside with cement-wash. There should further be provision for cleansing purposes, and the cleansing should receive more careful attention than is at present the case with the majority of these tanks. With regard to larger vessels I would urge that shipowners should take the advice of Dr. Collingridge, the Medical Officer to the Port of London, and encourage the perfecting of "distilling apparatus, rather than appliances for storage and filtration."

Antitoxine Treatment of Diphtheria.—In the report of Dr. Henry Kenwood, Medical Officer of Health, St. Mary, Stoke Newington, the following observations occur:—"Ample time has now been afforded for testing the efficacy of 'antitoxine' in the treatment of diphtheria, and the opportunities have been all too frequent during the past six or seven years. Good reports upon its employment come from all quarters of the globe, and the very few contrary statements which have come to hand have either been based upon inadequate trial or improper employment of the serum. The remedy is too generally used as a *dernier ressort* after the patient is moribund or requires tracheotomy, and even then it is notorious how rapidly the distressing symptoms, as a rule melt away. It is thought by some that although it does such a great deal of good during the acute attack, it does not diminish, even if it does not increase, the subsequent tendency to fatal heart failure. I know of no convincing statistics in support of this point, but it is conceivable that if antitoxine is the means of bringing a patient over the acute attack, it may appear to increase the number of deaths from subsequent heart failure from the circumstance that it enables many to reach the dangerous period following the acute attack, who otherwise would have died beforehand."

HASTINGS.—The Local Government Board has sanctioned the borrowing of the following sums, viz.: £744 for extending water mains; £7658, £3094, £1761, and £2803 for new water mains.

General News.

MERIDEN.—The Rural District Council has decided to purchase a steam-roller.

ST. DOGMELLS.—The Rural District Council is about to appoint a surveyor at a salary of £100.

ITCHEN.—A surveyor and sanitary officer is to be appointed for this new urban district, at a salary of £125.

REDRUTH.—The Urban District Council has obtained sanction for the balance of £460 of its water loan.

LLANGOLLEN.—The Urban District Council is reopening negotiations with the Vivod trustees with regard to the proposed water supply.

TAUNTON.—A Local Government Board inquiry has been held into the application of the Town Council to borrow £31,500 for waterworks purposes.

CREETING ST. PETER.—The East Stow Rural District Council has decided to apply to the Local Government Board for £350 for the erection of tanks, &c.

BERWICK.—The Town Council has decided to charge by meter for water used for trade purposes, and a committee has been instructed to prepare a scheme.

CLECKHEATON.—A Local Government Board inquiry has been held into the application of the North Bierley Joint Hospital Board to borrow £2300 for hospital extensions.

CORPACH.—Operations in connection with the introduction of a new water supply for Corpach have been commenced. The contractor is Mr. Robert Harper, of Fort William.

NEWPORT.—The Corporation is asking for the sanction of the Local Government Board to the borrowing of the £7500 for extensions to the Alteryn infectious diseases hospital.

CLONTARF.—A Local Government Board inquiry has been held into the application of the Commissioners for loans of £1000 for street widening and of £550 for laying water supply extensions.

DUNSTABLE.—In consequence of opposition to the proposed site for the new slaughter-house, a special meeting of the Town Council has decided to visit the spot before coming to any definite decision.

ANNAN.—The report and plans for a public slaughter-house prepared by the Surveyor have been agreed to by the Town Council. The cost is not to exceed £1000, and the site will be on the Burgh Merse.

PLYMOUTH.—As alterations to the city water scheme suggested by the Admiralty would involve an expenditure of an additional £200,000, and also in consequence of strategical reasons, it appears that the scheme is again doomed.

WISHAW.—At Westminster, on the 21st inst., a Select Committee of the House of Commons proceeded with the consideration of a Bill for the purpose of obtaining an additional supply of water for domestic and manufacturing purposes in Wishaw The Bill was opposed by the Middle Ward District Committee, the County Council of Lanark, and the Earl of Home.

LONDON, E.—The Vestry of St. George's East has decided to provide an underground public convenience for men in Cable-street, 20ft. west of Cannon-street-road, at an estimated cost of £550.

WOLVERHAMPTON.—The Town Council has accepted the tender of Messrs. Henry Willcock and Co., amounting to £3374 15s., for the erection of a first-class swimming bath and its appurtenances, on the north side of the existing bath buildings.

SWANSEA.—At a recent meeting of the Town Council it was decided to accept the tender of Messrs. Patterson and Son, Glasgow, at £255,747 16s. 6d. for the construction of the Cray Waterworks and tunnel, and to apply for a further loan of £100,000 towards the work.

CHELSEA.—The quarterly report of Dr. Louis C. Parkes, Public Analyst for Chelsea, was recently submitted to the Vestry. It was as follows:—"Twenty-four samples of milk were submitted to analysis during the quarter, twenty-two being genuine, one of inferior quality, and one adulterated with 10 per cent. of added water. Twelve samples of drugs and medical prescriptions were submitted to analysis. Seven of these were genuine samples, and five were deficient in strength below the standard prescribed by the British Pharmacopœia. Two samples of mustard, two of arrowroot, and two of cornflour were examined, all being genuine."

LIVERPOOL.—A Local Government Board inquiry has been held to inquire into the circumstances attendant upon the application of the City Council for sanction to borrow £38,000 for the purchase of a site at Fazakerley for an infectious diseases hospital. The Town Clerk explained that the land consisted of 113 acres, and the price the Corporation had agreed to pay for it, subject to the sanction of the Board, was £37,150, which roughly worked out at about £330 an acre. The Corporation did not propose at the present time to submit any plan to the Board showing how the site was going to be utilised, but merely to prove that it was desirable to acquire it for the purposes of future hospital development. The property was situated in Fazakerley, and stood at an elevation of 69ft. above Ordnance data.

Personal.

MR. W. C. WILLIAMS has been appointed Analyst for the County Borough of Bootle.

MR. HUGH JONES has been appointed Medical Officer of Health for the rural district of Dolgelly.

MR. J. H. HOLDING has been appointed Medical Officer of Health for the rural district of Bideford.

MR. H. M. APPS has been appointed Inspector of Nuisances for the rural district of Hollingbourn.

MR. COSMO GRANT has been appointed Medical Officer for the Hadleigh district of Rochford Union.

MR. R. H. ASTON has been appointed Medical Officer for the twelfth district of North Brierley Union.

MR. T. OLVER has been appointed Medical Officer for the third district of Plympton St. Mary Union.

MR. W. R. MCLEOD has been appointed Vaccination Officer for the Mitcham District of Croydon Union.

MR. E. V. PERRY has been appointed Medical Officer for the Great Witchingham district of St. Faith's Union.

DR. W. GROOM has been appointed Medical Officer for the first, second A, and eighth districts of Wisbech Union.

THE Council of the Sanitary Institute has transferred to the class of Fellows Mr. Wm. Spinks, A.M.I.C.E., of Leeds, and Lecturer on Sanitary Engineering at the Yorkshire College.

MR. J. E. ST. G. JOHNSTONE has been appointed Medical Officer for the Triley district of Tewkesbury Union; Mr. W. C. Devereux Medical Officer for the Tewkesbury district; and Mr. A. F. Turner Medical Officer of the workhouse.

Sewerage Schemes.

[TO MUNICIPAL ENGINEERS AND SURVEYORS.—The Editor will be pleased to receive items for publication relating to sewerage schemes projected or inaugurated, together with explanatory diagrams or photographs. The former should be drawn and lettered in black ink.]

MR. C. JONES has been retained to prepare drainage scheme for Billericay.

AT a recent meeting of the Roundway Parish Council an informal discussion took place upon the Breachfield sewerage scheme, which is likely to be an expensive matter to the parish.

TAUNTON Town Council has decided to apply to the Local Government Board for sanction to borrow £18,250 for adapting the present Taunton sewage works to the septic tank system, and completing the purchase of Lambrook Farm in connection therewith.

AT the last monthly meeting of the Bradford-on-Avon Urban Council Lord Edmond Fitzmaurice was asked to wait on the Local Government Board in London in order to secure replies to certain questions which have been asked in relation to the proposed scheme of sewage disposal.

A DEPUTATION of Acton Ward ratepayers recently visited the Shoreditch Vestry, calling attention to the inconvenience and ill-health they had suffered from the defective sewerage in Shrubland-road. In obedience to the commands of the Vestry many residents had had their drains re-laid, but all to no effect, for the builder informed them that there was not sufficient fall into the main sewer. In the summer it was a common practice to cover the ventilator in the road with a sack to keep back the noxious smell, and the residents were greatly disappointed that the road was not included in the scheme for dealing with the Haggerston sewerage. It was urged that the wishes of the deputation should be immediately carried out, but it was resolved to refer the matter to the Works Committee.

A Local Government Board inquiry has been held at Hornsey into the application of the District Council to borrow £3100, including £600 for surface drainage at Fortis-green.

The Tong District Council having made overtures regarding the sewage disposal of Tong village, the Drighlington District Council has decided to invite a deputation from the Tong Council to attend the next meeting regarding the question.

The Midhurst District Council has decided, in view of the fact that a Royal Commission has been appointed to consider the question of the drainage of small towns, to present a humble petition to the Local Government Board asking it to allow the Council to postpone the drainage scheme pending the report of the Royal Commission.

A Local Government Board inquiry has been held at Tavistock respecting an application for permission to borrow £300 for sewerage purposes in Tavistock Urban District. The Inspector thought the Local Government Board would not be likely to sanction £300 more being spent unless security were given that there would be an outfall.

The London County Council (Acton Sewage) Bill came on Thursday, the 21st inst., before the Select Committee of the House of Commons. It appeared from the opening statement of Mr. Pope, Q.C., that the object of the Bill was to require the Acton Local Board, whose sewage passes through the metropolitan main drainage system, to bear their share of the cost of the original construction of that system and its maintenance, the capital outlay having been some seven millions and the annual cost of maintenance about a quarter of a million. The Bill was again before the Committee on Friday, the 22nd inst., when further consideration was adjourned until Thursday, the 28th inst.

At a recent meeting of the Sanitary Committee of Pembroke Dock, the report of Mr. Beesley, C.E., on the amended scheme for sewering the town, was read. It will be remembered that the Local Government Board would not sanction any scheme which had an outlet higher up than the Carr Spit, and the engineer had to alter and amend his plans accordingly. The scheme as now propounded will entail expenditure of no less than £27,000—about £10,000 more than the original, and great indignation was expressed by the members on account of the opposition of the Local Government Board. This opposition is based on the assumption of injury to the "oyster beds" in the haven, whereas the "oyster beds" have no existence, only a few of the bivalves having survived the energetic operations of that little colony of fishermen and fisherwomen, the Langwms. The Committee passed a resolution condemning the amended scheme, because an outlet could be more easily found. It was agreed to point out to the Local Government Board the financial position of the borough, and also the fact that the Inspector reported favourably on the other scheme, and that the County Council had also reported favourably thereon.

A considerable area in the neighbourhood of the Borough, Southwark, is to be re-sewered. The estimated cost is £4222 12s. 7d., and the work will be carried out by the St. George's Vestry workmen. A loan of £4250 is being asked for from the County Council to defray the cost.

The method of utilising the town sewage which has been in vogue for some years at Congleton appears to be answering satisfactorily from the agricultural point of view. Mr. Brown, of Smithy Farm, Congleton, has been comparing the results produced by this and the ordinary commercial manures, and the outcome is greatly in favour of the sewage.

The recent opening of the Mangotsfield Sewage Works attracted a large number of visitors, who expressed much satisfaction with the scheme, and the excellent effluent resulting from the rapid purification process. A noteworthy feature is the method of construction, whereby complete purification works are erected upon a limited area of ground that formerly would have been considered impossible for the purpose. After passing the detritus and screening chambers, the sewage, of a strong domestic character, with some manufacturers' and slaughter-house refuse, is treated with ferozone, from 2 to 3 grains per gallon being found sufficient, it then flows through horizontal inlet pipes to 15in. vertical tubes in the centre of the Candy circular upward flow precipitation tanks, and falls, within 2ft. of the bottom, on to spreading plates. There is an outer cylinder 5ft. in diameter, reaching from about 6in. above water level to 6in. below the spreading plates; by this means further contact with the ferozone is given, and at the same time the precipitated solids overlying the bottom of the tank are not disturbed by the incoming sewage; a large volume is thus enabled to be rapidly dealt with, a continuous flow is maintained, and the effluent delivered without loss of level, a matter of great importance where the fall is limited. The tanks, two in number, are capable of dealing with a flow of one million gallons daily, and are fitted with Candy's patent automatic sludge removal apparatus; each tank is 24ft. in diameter, with 15ft. 6in. depth of sewage, the total area occupied by them being about 64 square yards. After leaving the tanks the effluent passes through clarifiers, of which there are five, each 7ft. in diameter by 8ft. high. The space occupied by these clarifiers (which are capable of dealing with a similar volume of sewage as the tanks) is about 63 square yards. The effluent from the clarifiers runs on to concentrated polarite filters, which can deal with 1500 to 2000 gallons per square yard per twenty-four hours. The superficial area of the polarite filters is about 480 square yards, so that the modern and successful purification installation for purifying one million gallons per day is contained within a total area of about one-sixth of an acre. A remarkably pure effluent is obtained, far above the ideal standard recommended by Sir Edward Frankland, of the late Royal Commission. Much satisfaction is felt because the sewerage and sewage disposal scheme, which includes eighteen miles of sewers, has been ably carried out under Mr. Le Maitre, C.E., of Staple Hill, Bristol.

Lighting.

THE London County Council has written the Islington Vestry agreeing to grant a loan of £13,662 for electric lighting works.

THE Corporation of Swansea has decided to borrow £60,000 for the electric lighting scheme, and to proceed with the work as soon as possible.

THE Great Marlow Gas Company has decided to extend the mains of the company to Bourne End and Wooburn at an outlay of between £4000 and £5000.

THE Town Council of Taunton has decided to apply to the Local Government Board for sanction to borrow £11,500 for the renewal of the electric lighting plant.

IT is intended to borrow £12,000 to defray the cost of a new retort-house and additional outlay on mains and meters for the Smethwick District Council's gasworks.

THE City Council of Manchester has decided to apply to the Local Government Board for sanction to borrow a further sum of £200,000 for various works of extension in the electric lighting department of the Corporation.

THE Metropolitan Radical Federation has passed resolutions protesting against the increase in the price of gas by the Gas Light and Coke Company, and expressing its opinion that the gas supply of London should be in the hands of the London County Council.

THE Aberystwith Gas Bill, which confers further powers on the gas company, recently came before the Chairman of Ways and Means as an unopposed measure. The Bill passed the Committee, and was sent for third reading in the Commons. It has passed the Lords.

THE Gas and Electricity Sub-committee of the Bradford Corporation has decided to light the two new tram routes to Great Horton and Bolton respectively by electricity. The lamps are to be placed upon the alternate poles carrying the wire to supply the motive power.

A LOCAL Government Board Inquiry has been held at Barking into the Urban Council's application for sanction to borrow £15,000 for the purposes of electric lighting. The application was opposed by the Gas Light and Coke Company, who are the largest ratepayers in Barking, and also by a number of smaller ratepayers.

THE Whitwick and Coalville Gas Bill, which has already passed through the House of Commons, came before the examiners of the House of Lords on the 21st inst. for proof of compliance with the further standing orders. There was no opposition at this stage, and the necessary formal proofs having been given the Bill was ordered to be reported for second reading.

AT a recent meeting of Edinburgh Town Council it was agreed to raise the salary of the resident Electrical Engineer from £500 to £600 per annum. Considerable discussion took place upon an amended proposal to erect fifty-seven electric arc lamps and three gas lamps in Grange-road, Inverleith-row, London-road, and Calton-road. A motion to disapprove of the recommendation was defeated, and it was thereupon resolved to add thirteen electric arc lamps between Donaldson's Hospital and Coltbridge.

AT a special meeting of the Oldbury Urban District Council held recently, the Clerk explained that at the last meeting of the Council he was instructed to try and arrange terms with the Midland Corporation for supplying Oldbury with electricity. The terms were that the District Council should obtain an order from the Board of Trade for supplying electric light for all public and private purposes, and that the Midland Corporation should also obtain an order to supply the manufacturers. The Midland Corporation had agreed to drop its application for an order altogether, leaving the District Council free to obtain its order for all purposes, and an agreement would be entered into for the Council to get the electricity in bulk from the company. It was agreed to accept these terms.

Law Cases.

BLACK SMOKE NUISANCE AT MANCHESTER.

CORPORATION FINED.

AT the City Police-court, before Mr. Headlam, a summons against the Corporation for disobeying an order made in January last to abate a nuisance arising from the emission of black smoke from one of the retort-houses at the Bradford-road Gasworks came on for hearing.

Mr. A. T. ROOKE, Superintendent of the Sanitary Department, appeared in support of the prosecution, which was instituted by Inspector Rowe as an inhabitant of the city, under the 105th Section of the Public Health Act. On the 14th March the Inspector took observations in the neighbourhood, and recorded four minutes' emission of black smoke in a period of thirty minutes.

Mr. T. MILLER, assistant solicitor to the Corporation, appeared for the defence, and read the following letter, which had been received from the Lord Mayor, with respect to the case:—"I am obliged to you for reminding me (as chairman of the Gas Committee) that the summons respecting smoke at Bradford-road Gasworks is to be heard at Court to-morrow. As you know, it is the meeting of the Council to-morrow, and so I cannot attend Court or should certainly do so. I should like personally to explain to the magistrates the extreme difficulty of our position, and how a gasworks of such dimensions cannot at all fairly be treated as an ordinary works or factory. Here we carbonise 150,000 tons of coal a year—a plant equal to making eight million cubic feet of gas per day, and there must be some smoke with all this work going on. The fact is, it would be just as sensible to require a miller not to make any dust. As a matter of fact,

we have the best smoke-prevention appliances; we burn nothing in our fires except coke, not an ounce of coal. I have now, or rather a few days ago, given special instructions to our new deputy manager to do all he can to have as little smoke as possible pass, and we cannot do more. Indeed, as we do not burn coal in any of our furnaces, I utterly fail to see how black smoke can be emitted, except in the ordinary process of carbonising."

MR. HEADLAM intimated that the Court could hardly accept such a defence, and imposed a penalty of 20s. and costs.

Correspondence.

We do not in any way hold ourselves responsible for opinions expressed by our correspondents.

BOVINE TUBERCULOSIS.

(*To the Editor of* THE SANITARY RECORD.)

SIR,—Would you permit me to draw your attention to the two following statements appearing in your Supplement on page 27 :—

"The fattening of cows in a moderate state of tuberculosis for slaughter." (Professor Delépine, of Owens College.)

"The condition of the carcase was fairly good, but on examination of the lungs I found evidence of tuberculosis." (S. Edmonson, Sanitary Inspector, Burnley.)

And the tuberculosed carcase was condemned.

Now, Sir, the question to be solved in this case is the following one. Assuming for a moment, and on the authority of Professor Delépine, that "a moderately tuberculosed beast is slaughtered" for food, how far may the disease penetrate into the system before it is unfit for human food? In the Burnley beast, the lungs were affected. Some practical butchers very strongly assert that until the kidneys are diseased, there is no danger in eating the flesh of such a beast after it has been properly dressed by a skilful butcher. The statement of the Professor seems to give strength to the statement of the butcher, and should I be correct in my surmise, a wrong has been done in the Burnley and kindred cases. But should those who contend for the destruction of all tuberculosed meat be right, I hope they will prove their case in the most satisfactory way possible.

The two statements that I have drawn your attention to cannot be allowed to pass muster in the name of sanitary science.—Yours faithfully,

SANITARIAN.

Public Works in Lancashire for the Relief of Distress, with Appendix on the Sewering of Towns and Draining of Houses. By Robert Rawlinson, C.E. 1s. P. S. King and Son.

Notes and Queries.

Subscribers have the privilege of obtaining advice in this column on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed to THE EDITOR, "Notes and Queries," THE SANITARY RECORD, 5, Fetter-lane, London, E.C 1

NOTE.—If an answer be required immediately, a stamped addressed envelope must be enclosed, when we will endeavour to furnish a copy of the answer by post, as owing to the large number of queries received we cannot guarantee the insertion of a reply in the succeeding issue.

1050.—SEWER AIR AND DISEASE: RELATIONSHIP.—"Surveyor" writes:—"Can you or any of the medical readers of the journal tell me if there is any relationship between abscesses, carbuncles, and sewage emanations? Some time ago I commenced taking gaugings of a sewer in a very awkward place, where for a short time I had to hang my head over a very offensive point in the sewer. Not long afterwards I had to undergo an operation for the removal of an internal abscess. On recovering from this, further abscesses have begun to appear. Is it possible there is some connection between my troubles and the sewage emanations?"

Answer.—It is well known that abscesses may be developed by inoculation of specific micrococci or microbes; and Klein states that he has come across the species *staphylococcus aureus*, closely similar to the species which is most common in acute purulent inflammation and in sores following the discharge of abscess, in blood, in air, and in dust. The inhalation of sewer air by those who, unlike sewermen, have not been acclimatised to it, is frequently productive of a well-recognised form of malaise, and in some cases of particular forms of disease. One or more of the symptoms predominate over the rest, according to the idiosyncrasies of the individual. While we are not aware that acute phlegmosis or abscesses have been noticeable in persons who have been exposed to the poison of highly offensive sewer air, we think, however, it is very possible that a relationship may exist between them; and we consider it a matter for investigation on the part of Medical Officers. We shall also be pleased to hear whether illness similar to that mentioned by our correspondent has been observable in the experience of Medical Officers, and also of Surveyors and Inspectors who have the superintendence of workmen employed in sewers.

1051.—PUBLIC HEALTH (SCOTLAND) ACTS: PRIVY ACCOMMODATION NOT ENFORCEABLE UNDER.—"R. B. M." writes:—"In what Act (Scotland) do you find a provision to compel the owner of every inhabited property to provide ashpit and privy accommodation for such property? State briefly the provision. I may point out that this question was set at a recent examination of the Sanitary Association held in Glasgow."

Answer.—We have gone carefully through the Burgh Police (Scotland) Act, 1862, and the Public Health (Scotland) Act, 1897, and are surprised to find that while in those towns only where the earlier Act applies the Local Authority may enforce the provision of water-closets to dwelling-houses, the Act of 1897 is silent as to provisions for enforcing privy or water-closet and ashpit accommodation for dwelling-houses. The omission is one which appears to us to be a singularly inept one. Sec. 16 (Sub-sec. 2) of this Act defines that a privy or ashpit, so foul or in such a state as to be a nuisance, constitutes a nuisance, and Secs. 29, 72, and 94 enable a Local Authority to enforce privy accommodation for schools, houses, factories, and lodging-houses, and Sec. 181 provides for the making of bye-laws for regulating the construction and arrangement of water-closets, earth-closets, and privies and ashpits, but none of them enable a Local Authority to enforce the provision of water-closet, privy, or ashpit accommodation to dwelling-houses, where no such accommodation at present exists. In other words,

there are no provisions in the Public Health (Scotland) Act, 1897, corresponding to Secs. 35 and 36 of the English Public Health Act, 1875, and as the law at present stands it appears to us a Local Authority have no power to enforce the provisions of water-closet, privy, or ashpit accommodation to either old or new dwelling-houses in districts other than those under the Burgh Police (Scotland) Act, 1862.

1052.—Scavenging Districts: Sanitary Conveniences in: Public Health (Scotland) Act, 1897.—"R. B. M." writes:—"What kind of sanitary conveniences would you recommend (*a*) for a village which is a special scavenging district, and (*b*) for one which is not?"

Answer.—In the unsatisfactory state of the law as at present, under the Public Health (Scotland) Act, 1897, (see Query No. 1051), it appears to us that while a Local Authority may recommend the provision of sanitary conveniences, they are in the invidious position of being unable to enforce their recommendation, for they have no power to do so under the Act of 1897. However, when a supplementary Act is passed to enforce the provision of sanitary conveniences we should recommend, in (*a*) privies or earth-closets with movable receptacles and portable ashbins, and in (*b*) privies or earth-closets with fixed receptacles which shall also serve as ashbins or ashpits. The capacity of fixed ashpits should not exceed eight cubic feet. The floor of the ashpit should be constructed of cement concrete, and should be 3in. above the level of the external ground, and the ashpit should be properly ventilated and provided with roof and impervious walls.

1053.—Sanitary Institute and Surveyors' Exams.—"Inquirer" writes:—"What are the necessary steps to take to become a member of the Sanitary Institute? Also if any examination is necessary, where is it held, and what are the fees for same? At the same time will you also give me some details as regards Institute of Surveyors?"

Answer.—The qualifications necessary for candidates for membership of the Sanitary Institute are that he shall be either (1) a Medical Officer of Health, or (2) hold the certificate of Surveyor or that in Practical Sanitary Science from the Sanitary Institute, or (3) be a Surveyor holding an appointment under a Parliamentary Sanitary Authority and a member or associate member of the Institution of Civil Engineers. The fees for the examination in practical sanitary science are £3 3s. when the examination is held in London, and £4 4s. when held out of London. We published the dates of forthcoming examinations in our answer to Query No. 1045 in our issue of April 22nd. Examinations for Surveyors are held by the Incorporated Association of Municipal and County Engineers (Secretary, Thos. Cole, 11, Victoria-street, Westminster, S.W.), and by the Surveyors' Institution (Secretary, Julian C. Rogers, Savoy-street, Victoria Embankment, London, W.C.). Information respecting the examinations may be had from the secretaries.

1054.—Building Bye-laws: Plans of Proposed Buildings.—"Nemo" writes:—"I submit sketch (not reproduced) showing proposed houses, and shall be glad to know if they can be approved as in accordance with the Bye-laws as to New Streets and Buildings, a copy of which I enclose."

Answer.—Our correspondent submits a block plan not drawn to scale, and does not show how many houses are to be built in the block, nor which is the intended front, side, or back of the houses. The sketch has been lettered, showing that on one side of the block is an 18ft. back street, on another side "8ft. path," and on a third side "proposed path." We trust correspondents will be careful to send us adequate particulars or we cannot advise them satisfactorily. The information now furnished is highly inadequate. Plans of the ground floor and backyards (if any) should have been sent. With such particulars as those given us we, however, think it will be found that the proposed houses could not be erected so as to comply with Clause 45 of the Bye-laws, and the plans should be disapproved in consequence.

1055.—Houses Built alongside an Old Highway: Bye-Laws as to Width.—"Scotia" writes:—"A person proposes to erect four houses alongside a country lane. There are already several isolated houses. The lane is only 18ft. wide. Could we insist on the four houses being set back, to allow for a 36ft. street? If we set these back, the road would still be only 18ft. wide on each side of these houses."

Answer.—It is a question of fact, as we have previously pointed out (Query 1033, April 8th), as to when an old lane or highway becomes a new street. Under any circumstances the owner can only be required to set back his forecourt wall (if such is to be provided) or the main front wall of his building 18ft. from the centre of the old lane or highway, when the Building Bye-laws prescribe the width of new streets to be 36ft. In the present instance we think it is very doubtful whether a new street is being formed. The facts are insufficient for us to more definitely advise.

1056.—Sewers: Local Authority cannot be required to Extend to every Block of Houses.—"Scissors" writes.—"Has there ever been a case decided that an Urban District Council is compelled to take a sewer up to a block of property and along a main road not previously sewered? If so, will you kindly give particulars? Will you also please give your opinion in regard to the following:—A new building is proposed to be erected abutting on a main road, which is not sewered. The proposed new building is 170ft. distance from the nearest sewer. (1) Is the Council compelled to extend the sewer up to the proposed new building? (2) Is the Council compelled to take it to within 100ft.? (3) Is it compulsory for the Council to sewer at all for this new building? (4) Has the fact that the new building is on a main road any bearing on its being sewered? (5) Can any property owners who have laid a sewer along a highway or main road recover the cost from the Council under any conditions?"

Answer.—We do not know of any decided case on the subject. (1) The Council cannot be required to provide a sewer for every individual house or block of houses within their district. (2) No; but the owner of the proposed house cannot be required to connect his drains to a sewer when this is more than 100ft. distant from the site of the house. He may, however, be required to construct a cesspool and connect his drains thereto (see Sec. 25 of the Public Health Act, 1875). (3) No; the Authority may, if they so decide, extend the sewer so as to bring it within 100ft. of the site of the house, and as the Sanitary Authority this course should be taken in preference to requiring the construction of a cesspool. (4) None whatever. (5) No; such sewers vest in the Local Authority immediately they are constructed under the provisions of Secs. 4, 13, 15, and 19 of the Public Health Act, 1875, and the Authority cannot be required to make any money payment for them.

1057.—Offensive Drains and Water-closets Inside Bakehouses: Proceedings.—"Bakehouse" writes:—"I shall be glad if you will kindly inform me under what Act and section notice is to be given for offensive drains and water-closets inside bakehouses?"

Answer.—It is an offence under Sec. 15 of the Factory and Workshop Act, 1883, to let or suffer to be occupied as a bakehouse, or to occupy as a bakehouse, any room or place which was not so let or occupied before the first day of June, 1883, unless the following regulations are complied with:—(1) No water-closet, earth-closet, privy, or ashpit shall be within or communicate directly with the bakehouse. (2) Any cistern for supplying water to the bakehouse shall be separate and distinct from any cistern

for supplying water to a water-closet. (3) No drain or pipe for carrying off fæcal or sewage matter shall have an opening within the bakehouse. And any person who lets or suffers to be occupied, &c., a bakehouse in contravention of this section shall be liable to a penalty of 40s., &c. If the above regulations are contravened, legal proceedings may be taken without first serving a notice. We recommend, however, that, previous to such proceedings being instituted, the owner or occupier be required by written notice to comply with the regulations, failing which the Local Authority should authorise their Medical Officer of Health, as provided by Sec. 17 of the Act, to institute proceedings.

1058.—SUN-BLINDS OVERHANGING FOOTWAYS: STATUTE AFFECTING.—"A. T. A." writes:—"Is there any Act in force to compel shopkeepers to keep their sun-blinds a certain height from the pavement?"

Answer.—The provisions of the Towns Police Clauses Act, 1847, Sec. 28, Clause 13, apply to the case, and precribes, *inter alia*, that a person who places any blind, shade, or other projection over or along any footway, unless the blind, &c., is 8ft. in height at least in every part thereof from the ground, shall be liable to a penalty of 40s. per day, &c. The provisions of this Act are incorporated, so far as relates to urban districts only, with the Public Health Act, 1875, by Sec. 171 of the later Act. A Rural Authority may, however, be invested with urban powers as above, under Sec. 76 of the Act of 1875.

1059.—DUTIES OF OFFICER: TAKING METER RECORDS.—"A. T. A." writes:—"Is it part of a surveyor's duty to inspect and take the readings of meters every month, or should this be the duty of the lamplighter? The gas is supplied by a company, and the Council wishes to check the meters with the company's account every month."

Answer.—We do not understand what meter readings are intended or suggested to be taken. If they are the street lamp meters, we consider it to be the duty of the surveyor to supervise the taking of the meter readings; and it is his duty to check the accounts and certify to their accuracy or otherwise before presenting them to his Council or Committee for payment.

1060.—BIOLOGICAL FILTERS: PLANS FOR.—"Nemo" writes:—"I shall be pleased to have your opinion on the plan submitted for filters for sewage from a pair of semi-detached villas. Would No. 1 or No. 2 plan be the best? I do not propose duplicate tanks, as there will be eight hours' certain rest each twenty-four hours, besides many intervals of rest during the day."

Answer.—The plan, not reproduced, shows in scheme No. 1 a proposed coarse bacteria filter, with outlet on the top of the filter. As we pointed out in reply to a similar query, No. 1043, in our issue of April 22nd, such a mode of construction would result in failure. Scheme No. 2 shows the effluent drain leading from the bottom of the coarse and fine-grain filters, and is much more practicable. But the proposed method of application of the sewage, which would really be on the continuous system, would not produce satisfactory results. We have repeatedly pointed out, in reply to similar queries, that the application of the sewage must be intermittent, and so arranged that the filter must be provided with a valve on the drain leading from the bottom of the filter, which should be closed while the filter is being charged, and so that the sewage may be confined for two or more hours therein and then drawn off, leaving the filter perfectly at rest for

a period equal to that at which it has been under work. Duplicate filters should be provided in order to obtain satisfactory results.

Contracts Open.

The dates given below are the latest up to which tenders can be received.

STALYBRIDGE.—May 2nd.—Sewers, &c.—Mr. J. N. White, Town Hall, Stalybridge.

HORSLEY (BELPER).—Waterworks.—Mr. Joseph Pym, clerk, Belper.

AMBLE (NORTHUMBERLAND). — May 3rd. — Scavenging.—Mr. W. Gibson, surveyor, 31, Queen-street, Amble.

BRIGHTON.—May 3rd.—Wells, &c.—Mr. Francis J. Tillstone, town clerk, Town Hall, Brighton.

CARLISLE.—May 4th.—Removal of Ashes.—The Clerk, 25, Lowther-street, Carlisle.

BLAYDON-ON-TYNE.—May 5th.—Scavenging.—Mr. Robert Biggins, sanitary inspector, Council Offices, Blaydon-on-Tyne.

BELFAST.—May 5th.—Waterworks—Mr. Richard Hamilton, secretary, Waterworks Office, Belfast.

RUNCORN. — May 6th. — Extension of Sewerage Works.—Mr. William Diggle, Holly Bank, Frodsham.

WOKINGHAM.—May 11th.—Re-sewering Roads, &c. —The Surveyor, Town Hall, Wokingham.

DUBLIN.—May 12th.—Cisterns, &c.—Mr. Owen Armstrong, secretary, Irish Lights Office, Dublin.

Vacancies.

ASSISTANT SURVEYOR (LONDON, W., May 2nd).—For the Vestry of Paddington. Salary £300 per annum, rising by annual increments for each year of approved service of £25 to £500 per annum. Surveyor's Department, Vestry Hall, Paddington.

BOROUGH SURVEYOR AND ENGINEER (KING'S LYNN, April 30th).—Salary at the rate of £200 a year, rising by annual increments of £25 to a maximum of £350 a year. Town Clerk, Town Hall, King's Lynn.

CLERK OF WORKS (POKESDOWN, BOURNEMOUTH, May 2nd).—For the Urban District Council. Salary £3 3s. per week. Mr. E. Wembridge Ingamells, engineer, Pokesdown, Bournemouth.

CLERK OF WOKRS (HANDSWORTH, May 9th).—For the School Board. Salary £3 per week. Thomas H. Moon, clerk.

CLERK OF WORKS (WEST BRIDGFORD, May 2nd).—For the Urban District Council. Salary £2 10s. per week. Mr. W. H. Redgate, clerk, Bentinck-buildings, Wheeler-gate, Nottingham.

DRAUGHTSMAN (GOLD COAST, WEST AFRICA, April 30th).—For Public Works Department, Gold Coast, West Africa. Salary £250 per annum for the first eighteen months, £275 for the next eighteen months, £300 for any further period for which he may be engaged. Crown Agents for the Colonies, Downing-street, London, S.W.

ENGINEER (LONDONDERRY, May 3rd). — For the Corporation. Sir R. Newman Chambers, town clerk, Guildhall, Londonderry.

INSPECTOR OF NUISANCES (BROMLEY, May 14th).—For the Rural District Council. Salary £150 per annum, inclusive of all expenses. Application forms can be obtained at the Clerk's Office, 96, High-street, Bromley.

INSPECTOR OF NUISANCES (WHITBY, May 2nd).—For the Urban District Council. Salary £70 per annum. Mr. William Seaton Gray, clerk, Whitby.

MEDICAL OFFICER (MIDDLESBROUGH, May 2nd).—For the Corporation. Salary £350 per annum. Mr. Geo. Bainbridge, town clerk, Middlesbrough.

SEWAGE WORKS MANAGER (HEYWOOD, April 30th).—Mr. J. H. Baldwick, town clerk, Municipal Buildings, Heywood.

SURVEYOR, &C. (SOOTHILL, BATLEY, May 2nd).—For the Soothill Upper Urban District Council. Combined salary £104, with house, coal, and gas free. Mr. L. W. Taylor, clerk, Batley.

SURVEYOR (EXMOUTH, May 2nd).—For the Urban District Council. Salary £160 a year. Mr. H. S. Adams, clerk, Public Hall-chambers, Exmouth.

SURVEYOR'S ASSISTANT (LONDON, S.E., May 3rd).—For the Lewisham Board of Works. Salary 30s. per week, with an annual increase of 5s. to a maximum of 50s. The Board's Office.

To Surveyors, Sanitary Inspectors, &c.—First-class Cycles at reasonable prices. Don't place your orders elsewhere until you have seen our post-free catalogue.—MELROSE CYCLE COMPANY, Coventry.

COMPETITIONS.

FORMBY (LANCS), July 1st.—Sewerage Scheme.—The Formby Parochial Committee invite competitive schemes for the sewerage of a portion of the township of Formby. Premiums are offered amounting to £100 for the scheme considered first in order of merit, £50 for the second, and £25 for the third. Mr. J. H. Havelock Sutton, Piercefield-road, Formby. A professional assessor will be appointed to adjudicate upon the plans.

DR. TIBBLES' VI-COCOA.

ARTICLE No. 6.

ITS ADVANTAGES OVER TEA AND COFFEE.

COCOA has been so long before the public, and is so largely used as a beverage in various forms, in some of which the fat is removed, and in others in which the fat is not only removed but starch is added; and others, again, in the forms of highly flavoured and sweetened chocolate, that it is not surprising attempts should be made to still further improve it. The modern crusade against alcoholic liquors has led to the disuse of malt and hops, in the form of drinks, by a very large number of persons to whom these products would prove valuable from the point of view of health. The valuable property possessed by malt of aiding the digestion of starch and of starchy matters by means of the diastase it contains, has received general recognition by the public as well as by the medical profession, in the extensive use that is made of extract of malt. A few preparations containing hops in the form of a beverage suitable for temperance advocates have also been introduced. But it remained for Dr. Tibbles to suggest the addition of these two important and valuable substances to cocoa, so as to form a non-alcoholic domestic beverage.

It would not be convenient to add them to coffee, since they can only be conveniently added in the form of powder, and as coffee is generally preferred in the freshly ground state, they would have to be added at the time of preparing it.

It would be equally difficult to add them to tea so as to form a uniform mixture. With cocoa they can be added mixed in any proportions; but it is only in a certain definite quantity that they can be added, so that the bitterness of the hop does not form a prominent feature and interfere with the delicate aroma of the cocoa.

Both tea and coffee contain caffeine as the active principle, but also small quantities of volatile substances, which in some constitutions cause unpleasant symptoms. Thus tea, especially Indian and Ceylon tea, produces in some persons a nervous or tremulous sensation, also symptoms resembling gastric catarrh, and in other cases extreme sleeplessness. Coffee, on the other hand, produces constipation, and in others the reverse.

There are other beverages containing caffeine largely used in other parts of the world, such as Paraguay tea, and guarana in Brazil and Central South America generally, which do not meet with acceptance with Europeans, who need to become gradually accustomed to their use. In Central and Northern Africa the kola nut is similarly employed. All these contain the same active principle, caffeine. It appears, therefore, that in tropical regions, where there is less inclination to a healthy amount of exercise than in colder climates, human nature instinctively craves for some stimulant that will produce the same effect as exercise, viz., to increase the circulation. Caffeine does this by stimulating the action of the heart. In populous countries where a large proportion of the population are engaged in sedentary work, or work which prevents a healthy amount of exercise in the open air, the same necessity for such a stimulant exists. Kola is without the fragrance of coffee or the aroma of tea.

Although it has been analysed by several skilled chemists of the highest reputation, it has never been found to contain any deleterious ingredient whatever. It therefore possesses an advantage over both tea and coffee.

Kola, when added to cocoa, forms an important adjunct, giving to it the stimulating and invigorating properties of caffeine, and, in conjunction with malt and hops, making as perfect a beverage as has yet been devised.

The importance of Kola has of late years been so thoroughly recognised by the Governments of France and Germany that extensive trials have been made with it in the form of chocolate for use in the army. In Great Britain attention has been directed to its value in the "Bulletin" of the Royal Gardens at Kew (November, 1890), and plants have been distributed to various British Colonies. From this publication (p. 259) the following extract is taken, being part of a communication addressed by Mr. G. A. Stevens, H.B.M. Consul at Bahia, to the Marquis of Salisbury:—

"The West African carriers at this port, who use Cola, and carry the bean wrapped in banana leaves about their person, are, as a whole, not, physically speaking, superior men to the Brazilian negro; and yet the African, through constantly masticating Kola, can withstand and endure labour and fatigue which no Brazilian carrier can withstand; and where, for instance, it takes eight Brazilian negroes to carry a load with difficulty, four African porters carry it cheerfully almost always, even though ascending a hill, singing and chanting the whole time as they trudge along, but never without a bit of Kola bean in their mouths; and as the discharging of vessels is paid by weight as a rule, the African gangs, who have less hands, earn twice as much; and while they hoard and save, the Brazilian porter lives from hand to mouth, spending in rum, under the impresston that it tends to strength, three times the amount that the African lays out daily in Kola beans, which are not intoxicating and in no way injurious, but act as a nutritive, and although not stimulant, yet produce vigour and freshness."

A little book containing the reports of the very highest medical experts and analysts in the United Kingdom, showing the advantages of Dr. Tibbles' Vi-Cocoa over all other food products, will be forwarded post free to any medical man on application (a post card will do), along with a large sample tin.

Address: DR. TIBBLES' VI-COCOA, LIMITED, 60, 61, and 62, Bunhill-row, London, E.C.

SITUATIONS.

VACANT.

☞ *Advertisements of Situations Vacant are inserted at the rate of Sixpence per line (prepaid), minimum three lines—eight words to line. Special rates for a series.*

WANTED.

THE SANITARY RECORD *will be found an excellent medium for those who are desirous of seeking Situations in the Offices of Surveyors, Sanitary Inspectors, Sanitary Engineers, Architects, &c. The charge for such advertisements (prepaid) is Sixpence per line. Minimum three lines—eight words to the line.*

☞ **Advertisements for this Department must reach us by Tuesday morning in each week, at latest.**

SANITARY INSTITUTE EXAMINATIONS.

TUITION BY CORRESPONDENCE.

An Engineer and Surveyor (Mem. San. Inst.), Certificated Surveyor and Inspector, prepares students for these Exams. by Correspondence through the post.

Fees strictly moderate. Cramming studiously avoided.

The course of tuition is arranged so as not only to qualify the student for passing the exams., but what is of equal importance, viz., that he may become a thoroughly efficient Inspector.

On successfully passing the exams., all possible assistance and advice is given to help forward intending candidates for public offices.

Many of my old pupils are now filling positions with salaries of over £120 a year.

For terms, &c., address "C. E.," care SANITARY RECORD, 5. Fetter-lane, London, E.C.

SANITARY ASSOCIATION OF SCOTLAND

EXAMINATIONS IN SANITARY SCIENCE.

Examinations for Certificates of Competency in Sanitary Science are held each year as follows, viz.:—In Glasgow in April, in Edinburgh in October, and at such other time and place as the Board of Examiners may determine.

Entrance Fee £2 2s.

For further particulars apply to

GEORGE MIDDLETON, M.A., LL.B.,
Writer, 92, Bath Street, Glasgow,
Secretary to the Board of Examiners.

A Stamped Addressed Envelope must accompany all letters requiring an answer.

SANITARY INSTITUTE EXAMINATIONS.

SPECIAL Corresponding Classes for the **Practical Sanitary Science,** and **Sanitary Inspectors' Examinations** of the **Sanitary Institute, 1898,** conducted by a gentleman holding appointments as Urban District Council Engineer and Sanitary Inspector, holder of three certificates from the Sanitary Institute, First-class Honour Medallist Hygiene, &c. Hundreds of successes.—For all particulars, testimonials, &c., apply Mem. San. Inst., Office of THE SANITARY RECORD, 5, Fetter-lane, London E.C.

OFFICIAL ADVERTISEMENTS.

ISLE OF WIGHT RURAL DISTRICT COUNCIL.

INSPECTOR OF NUISANCES AND SURVEYOR.

APPLICATIONS are invited for the APPOINTMENTS of INSPECTOR OF NUISANCES and SURVEYOR, for the "East Medene," comprising an approximate area of 42,500 with an estimated population of 14,242, at a salary of £150.

Applicants must be under 35 years of age, and must hold either a certificate of the Sanitary Institute of Great Britain, or some other certificate approved by the Local Government Board, subject to whose approval the appointment (made from year to year) will be made.

Applications, in the handwriting of the candidates, stating age and qualifications, accompanied by copies of not more than three recent testimonials, must be received by me on or before Wednesday next, the 4th May.

By order,
FREDERIC STRATTON,
Clerk.

R. D. C. Offices:
Pyle-street, Newport, I.W.,
21st April, 1898.

All Sanitary & Scientific Publications.

WILL SHORTLY APPEAR IN THE

Sanitary Record

A SERIES OF ARTICLES

ENTITLED—

"THE CHEMICAL AND BIOLOGICAL EXAMINATION OF WATER,"

BY

C. G. MOOR, M.A., F.C.S.

These Articles, which have been expecially written for THE SANITARY RECORD by Mr. Moor, will be fully illustrated, and will embody the results of the latest researches on this all-important subject.

The writer holds a unique reputation as joint author (with Mr. T. H. Pearmain) of "Applied Bacteriology" and "Aids to the Study of Bacteriology," both of which works have received high encomiums from the *Lancet*, the *British Medical Journal*, the *Chemical News*, &c., and we have no hesitation in commending this new series to the notice of all Public Bodies who are interested in the purity of public water supplies.

THE

PENSION QUESTION SOLVED

How Public Health Officials may Secure a Pension in Ten, Fifteen, or Twenty Years of from £10 to £100 or more per annum.

This question is admittedly one of paramount importance to all Public Health Officials who are dependent upon their own exertions to provide for the future, and one which has for some time exercised the minds of those who are so situated. It is therefore a matter for general congratulation that a satisfactory solution of the problem has been arrived at. Those who wish for particulars are invited to fill up and return to the undersigned the subjoined form, when the fullest information will be forthcoming from a source which is highly approved and recommended by THE SANITARY RECORD.

Please inform me what Annual deposit would be required to provide a Pension of £_____ per annum in _____ years, and what sum my family would secure in the event of my decease previously; also any other investment advantages offered on my surviving.

Name _____

Address _____

_____

Age _____ *(nearest Birthday).*

Address—"Pension," care of Sanitary Record, 5, Fetter-lane, London, E.C.

NOTICES.

ANNUAL SUBSCRIPTIONS. — The Annual Subscription to "The Sanitary Record," paid in advance, is 12s. 6d. This includes postage, and a Copy of the Diary, post free.

SUBSCRIBERS RESIDING in SCOTLAND and IRELAND are requested to pay by P.O. and NOT *by cheque. If cheques* BE *sent they must be drawn for 13s.*

MSS. cannot be returned unless accompanied by a stampea directed envelope.

Advertisements cannot be inserted unless received before Four o'clock on the TUESDAY of each week.

All communications should be addressed to the EDITOR, at 5, FETTER LANE, London, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, Ld.

THE

Sanitary Record,

MAY 6, 1898.

THE REPORT OF THE TUBERCULOSIS COMMISSION.

THE issue of the long-expected report of the Royal Commission on Tuberculosis overshadows in interest and importance all the other sanitary news of the past few days. It is an epoch-making document, and is certain to be followed by legislation at no distant date. This is the third Commission that we have had within the last ten years to inquire into the subject. The last was the Royal Commission of 1890, which established the foundations of our knowledge as to the relation between tuberculosis in man and the means by which it is imported through the flesh and milk of tubercular animals. Once the conditions that governed and gave rise to the disease were known,

the next step was to determine the practical measures that might be adopted to protect humanity from this insidious foe by the regulation of food supplies, and this is the task which the present Commission has been engaged in during the past two years. The inquiry has been a most exhaustive one, and the report and recommendations embody the most up-to-date knowledge that is obtainable both in this country and on the Continent as to the administrative procedure that is best calculated to prevent or to check the spread of tubercle in man and in cattle.

Owing to the lack of accurate statistics, the Commission are unable to specify the exact prevalence of the disease among British cattle, but they are clear that it is much more widespread than is generally supposed; and they find that it exists to a far greater extent among cows than other bovines, principally on account of their greater age, their close confinement, the severe drain caused by milking, and the common practice of maintaining a high temperature in byres, which is rarely associated with efficient ventilation. They also corroborate the report of the previous Commission in finding that, while there is always a certain amount of danger in consuming the flesh of tuberculous animals, the danger in regard to milk is far greater, milk containing tubercular matter being indeed the principal source of infection. The danger is greatest when the udder is affected; but as it is often difficult to detect the pressure of tubercle in the udder during the earlier stages, and as the spread of the disease in the udder is very rapid, the practical conclusion is that no tuberculous animal of any kind should be allowed in the dairy. There are also findings with regard to meat inspection, which they hold to be unsatisfactory, on account of its being entrusted to men without special training, and hence there is a total absence of uniformity; with regard to milk inspection, which they find to be non-existent; with regard to the use of tuberculin, which they are satisfied is an almost infallible test for tuberculosis in the hands of a competent veterinary surgeon; with regard to compensation, and a number of other matters.

Coming now to the recommendations appended to the report, we find these divided into two groups—those relating to meat, and those relating to milk. The recommendations as to meat aim at two things: (1) the suppression of all private slaughter-houses, all meat being dealt with in public slaughter-houses, where it can be properly inspected by duly qualified Inspectors; and (2) that the important duty of meat inspection shall be entrusted only to such men as have passed a qualifying examination in certain specified subjects. They need not necessarily be veterinary surgeons, though it is probable that the veterinary colleges will claim that they should be. The duties of Meat Inspectors, it is proposed, should be regulated from time to time by instructions from the Local Government Board; but pending the issue of such instructions, certain principles are laid down for their guidance in the inspection of carcases and the seizure of unsound meat. In many cases, the carcase, if generally healthy though locally affected, need not be condemned, only those parts that contain tuberculous lesions being liable to seizure.

The chief recommendation to secure the purity of milk is that notification of every disease in the udder should be made compulsory, under penalty, on the owners of all cows; and this is followed by a recommendation that Local Authorities should be invested with powers of systematic inspection and analysis. Medical Officers should also be empowered to suspend the milk of any suspected cow, and to prohibit the sale of milk from a cow with a diseased udder. Then come important recommendations with regard to the regulation of cowsheds and byres. Certain leading principles are laid down under this heading, including the provision of proper water supply and drainage facilities, of a minimum cubic space of from 600ft. to 800ft., and a minimum floor space of 50ft. for each adult beast, and of sufficient light and ventilation, the last named being the most essential requirements. These requirements are directed chiefly to dairy accommodation in populous districts; the conditions in rural districts vary so widely with local circumstances that no minimum cubic space can be specified, the one end to be kept in view being the maintenance of reasonable ventilation without draughts.

All these precautions, however, are recognised to be but temporary and uncertain palliatives so long as no attempt is made to eliminate the disease from the animals themselves, and this part of the inquiry may therefore be regarded as the groundwork of the whole. The Commission are of opinion that if the tuberculin test is skilfully applied, and the animals which react are carefully separated from the healthy ones, the disease may be reduced to small proportions in a limited time and at a moderate expense. The precedent set them by the Danish Government forms the basis of their recommendation that funds should be placed at the disposal of the Board of Agriculture for the preparation of commercial tuberculin, and that stockowners should be encouraged to test their animals by the offer of a gratuitous supply of tuberculin and the gratuitous services of a veterinary surgeon to see the test applied. This offer is, however, to be conditional on the owners undertaking to isolate reacting animals from healthy ones, and to keep their stock under satisfactory sanitary conditions, especially in regard to air space, light, and ventilation. In Denmark the results of the Government's experiment have been most encouraging, and if similar results are obtained in this country we may hope to see our agriculturists gradually eliminating the scourge of tuberculosis from their herds, and enabling us to look forward to the day when we may be able to check the spread of the disease among mankind.

Notes.

Outbreak of the Plague in Calcutta.

It is evident to those who follow with interest the course of public health in the world, that so far from there being any sign of the end of the plague in India, we are apparently on the eve of a fresh outbreak, which there is only too much reason to fear may prove more disastrous in its results than that which has scourged Bombay for the past eighteen months. From the first the

danger of the epidemic spreading through India was foreseen and guarded against; the most careful precautions were taken to draw close the sanitary cordon round Bombay; and hitherto these efforts have met with the most gratifying success, so much so that the disease has been almost entirely confined to Bombay and the outlying districts. But now comes the news that it has broken out in Calcutta. Several suspicious cases of illness having occurred there, cultures of the bacilli have been sent to Bombay to be examined by Professor Haffkine, and have been pronounced by him to be those of bubonic plague. There seems to be no doubt as to the correctness of the report, and it is further stated that the inhabitants have already taken fright, and the exodus among the wealthier natives, at least, has commenced.

The Sanitary Conditions of Calcutta.

This is most disquieting news, though it cannot be said that it occasions us much surprise. It would have been surprising indeed if, after the long-continued ravages of the plague in western India, it should never have found its way to the eastern side of the peninsula. None the less, however, is it a matter for deep regret that this terrible scourge should have made its appearance in the densely-populated presidency of Bengal. It is said that the sanitation of Calcutta is superior in some respects to that of Bombay; but that is not saying much, and it cannot be forgotten that it is not long since the Lieutenant-Governor had to formulate a proposal for the reconstruction of the municipality, on the ground that the Local Authority had failed to discharge its sanitary obligations effectually. The situation of the town, too, one would imagine, is less favourable than that of Bombay, as the latter place is insular, and has the advantage of being swept by fresh breezes from the Indian Ocean. On the whole, we believe that the conditions in Calcutta indicate that if the plague once gains a footing there it will be extremely hard to eradicate, and will, before it is over, occasion incalculable havoc and loss to the city, both in life and in trade, perhaps more so even than in Bombay.

Lessons for the Administration.

In facing at the outset the question of what preventive measures should be taken, the Government have for their guidance as an object lesson the experience of Bombay. And the one clear lesson that has been so gained is, that where sanitary issues are involved, the native rulers, who form the Local Authority, are not to be relied on. The Oriental mind seems unable to grasp those elementary principles of hygiene which are now so familiar to us Europeans. With them it is certainly true that cleanliness is next to godliness, but, unfortunately, with their notions of godliness, these two principles are frequently brought into hopeless collision. We think, then, that it would be wise for the Government to follow the advice that has been urged upon them, to supersede entirely the Municipal Authority in all questions of sanitary administration, and to place the sole responsibility in the hands of a specially organised department, and, above all, to be determined from the first firmly and consistently to enforce the sanitary regulations that the situation requires, even in the face of native hostility and prejudice.

The London Improvement Bill.

When we discussed, some time ago, the principal issues raised by the Bill promoted by a London Syndicate for the improvement of Westminster, we indicated our objections to the measure as it was framed, the leading one being that it was manifestly being run as a commercial and speculative undertaking; and was not likely, therefore, to conduce to the *real* improvement of the district, which, as it stands, is dear to many persons on æsthetic grounds, or on account of historical associations. The objectionable character of the Bill was fairly well indicated by the division in the House of Commons last week, when it was rejected by a vote of 336 to 84. At the same time, as we have already pointed out, it does not follow that because this particular measure is condemned, all attempts to improve the sides of the Thames, or the approaches to the Houses of Parliament, are subject to a like fate. On the contrary, there is abundant room for such alteration as, without robbing the locality of any of its beauty, would rather adorn it; and certainly improve it from a sanitary point of view. Such an improvement will probably come some day; but it will be a large undertaking, and will have to be at the public expense, as it will most certainly not be a dividend-paying venture.

The Electrical Energy Inquiry.

The inquiry that is being conducted by the Joint-Committee of the two Houses of Parliament into the subject of electrical energy, its generation and supply, will, it is to be hoped, result in considerable amendments of the law, which will still further stimulate the development of this great industry, and help to bring electricity, both as a motor and as a lighting agent, yet more within the reach of every one. It is not exactly creditable to this country that we should lag so far behind continental nations in this matter of electrical supply; and there is no reason why it should be so. But at present electrical companies and corporations feel themselves rather hampered in some respects by the existing state of the law; and perhaps this is, to a certain extent, accountable for our backward position. Among the amendments of the law that have been urged before the Parliamentary Committee, two of the principal ones are (1) the necessity for conferring on electric supply companies compulsory powers for the acquisition of land; and (2) power to go outside the area of distribution for the erection of generating stations, possibly having one large central generating station, from which the various districts of distribution would be supplied. The only difficulty with regard to the latter proposal was pointed out by Sir Courtenay Boyle, of the Board of Trade, when he indicated the conflict of authority that might thereby arise; and especially when the time came for purchase by the Local Authority. Apart from this difficulty, however, it was admitted that both proposals would help to solve many troublesome problems.

The Question of Long-distance Distribution.

An interesting issue was raised in connection with the question of long-distance distribution of electrical energy, which is an established fact on the Continent, while here it is still quite unknown. And yet Mr. Swinburne, vice-president of the Institution of Electrical Engineers, bore emphatic testimony to its advantages, both in the way of convenience and of cheapness. He said that the adoption of this system would enable small villages and scattered districts which could not afford to have their own gasworks to have the electric light, for, if they were on the route of the electric main, they would be able to utilise the supply without the necessity for finding the capital necessary for the construction of central generating stations. And not only so, but it would be found that it would pay. Of course, the same source of electrical energy that could be utilised for the lighting of a village could also be used as a motor power, and Mr. Swinburne placed before the Committee a most attractive picture of what might be expected in this direction. There was, in his opinion, no practical objection to every small cottage in the country being supplied with its motor, under a properly devised scheme, capable of being applied with facility to a variety of beneficial purposes in the household and on the farm. In Germany, indeed, some advance towards this consummation has already been made; and if it has been shown to be possible there, why not here, too?

"Fair Wages" Conditions in Contracts of Urban Sanitary Authorities.

An interesting Parliamentary Return has been issued by the Local Government Board for the purpose of showing the practice of the various Urban Sanitary Authorities throughout England and Wales with regard to conditions of employment inserted in their contracts for the execution of public works. The growth of the spirit which is the underlying principle of trades unionism has led many public bodies, especially in the larger centres of population, where the labour question is more prominent, to impose certain conditions on contractors, either as to the wages paid by them to their employés, or as to the other terms of employment. An analysis of this return shows in a tabular form how far such conditions attaching to public contracts are insisted on in the different Urban Sanitary Districts, and for this purpose the districts are divided into (1) County Boroughs; (2) Non-County Boroughs; and (3) Other Urban Districts, the population represented being stated in every case.

How Enteric Fever is Spread.

We have before us the report of some investigations into the aërial transmission of enteric fever, which seem to establish that the bacillus of this disease may live for a considerable time in arable and other soils, and even in ordinary dust, as it always contains a certain degree of moisture which enables it to exist in the most unlikely conditions. The possibility of the bacillus being found in an active state in such circumstances leads to the further conclusion that the poison of enteric fever may be spread by currents of air carrying the infected particles of dust, and depositing them on articles of food, which provide excellent lodgment for the bacillus, and at once become fresh centres of infection. An outbreak of enteric fever among our soldiers during the Egyptian campaign of 1885 is believed to have been thus caused. It has also been found that the turning up of the earth of a back court, for repair of the drains, may, especially in dry weather, lead to similar disastrous results. One practical deduction to be drawn from this knowledge is that, as the earth of back courts in the poorer districts of a town is always liable to a considerable amount of organic fouling, such back courts should be provided with impervious pavements, which not only prevent absorption, but are also easily cleansed; and another is that in enteric districts the pavements should be repeatedly scavenged with a plentiful use of water. Every means, in short, should be adopted to prevent the lodgment of the bacilli in the soil.

Analysis of the Conditions.

The conditions imposed on contractors naturally vary very widely, but they may be broadly grouped under five headings—at least those that relate to the rate of wages specified in the contracts. The rates may be specified as (1) those current in the district; (2) those recognised by trade unions; (3) those agreed on by associations of employers and employed; (4) those prevailing or recognised at the date of the contract; or (5) those fixed in the contract itself. Besides these we find various conditions imposed as to the terms of employment, other than the rate of wages. Some Authorities indicate what these conditions should be without making them part of the contract; others are silent on the subject; and a few, chiefly in the smaller districts, dispense with formal contracts altogether. Now, of the 1086 urban districts which the return covers, representing a population of about seventeen millions (London being excluded), it appears that 912 districts, with a population of eight millions, leave their contractors unfettered in the matter of wages to be paid to their employés; while 163 districts, with a population of nine millions, lay down what the terms of employment are to be; and 11, representing a population of half a million, though indicating them, do not make them binding. It is to be observed that these conditions are chiefly to be found in the contracts of the larger urban districts, such as the county boroughs, the greatest freedom prevailing in the smaller centres. Another feature to be noted is that where the rate of wages is specified, in by far the majority of cases, it is the rate "current in the district." If we add London we find that the urban districts of England and Wales, with a total population of about twenty-one millions, may be divided into two classes, of which the first, with an aggregate population of about thirteen millions, includes all districts of which the Local Authorities impose conditions of some kind as to wages in their contracts; and the second, with a population of about eight millions, includes those which dispense with such conditions.

Mr. T. McKinnon Wood, Chairman of the London County Council, has been entertained at dinner by the members of the Old Millhillian Club.

LIME, MORTAR, AND CEMENT: THEIR COMPOSITION AND ANALYSES.

By W. J. DIBDIN, F.I.C., F.C.S., &c.

CHAPTER II.

CLAYS AND SANDS.

Clay.—On turning to the subject "clay" in any work on chemistry, we shall find that the description of clay comes under the head of "alumina," which in the form of silicate is the constituent of an enormous number of rocks, *e.g.*, the felspars, amongst which may be mentioned irthoclase (K_2 Al_2 Si_6 O8), lencite (K_2 Al_2 Si_4 O_{12}), sodalite (2 Na Cl3 Na_2 Al_2 Si_2 O8), and albite (Na_2 Al_2 Si_6O_{16}). The various felspars and micas (also aluminium silicates), together with quartz, &c., constitute primary rocks, such as granite, gneiss, syenite, porphyry, &c., mica being a constituent of slate. The felspars by natural disintegration give rise to various clays, the purest forms of which, such as kaolin, or white china clay, pipe clay, fullers' earth, &c., correspond more or less to the composition $Al_2O_3, 2Si\,O_2, 2H_2O$; white marl, loam, &c., are classes containing various admixtures, such as calcium carbonate, oxides of iron, and magnesia, &c.

These primary considerations clearly show us that clay is a compound of alumina (oxide of aluminium) with silica (oxide of silicon), the latter of which we know in its natural state, in a considerable degree of purity, as flint. The practical classification of brick earths involves a curious contradiction of terms in the case of pure clays composed of silicate of alumina with but a small proportion of lime, magnesia, soda, or other salts, these being known to the brickmaker as "foul clays." Loams, or mild clays, consist of clay and sand, and are sometimes called "sandy clays." Marl, or calcareous clays, contain a large proportion of carbonate of calcium. Malm is an artificial imitation of natural marl, and is made by mixing clay and chalk in a wash mill, and is sometimes called "washed clay."

It will not be without interest to follow the formation of clay from the decomposition of the rocks from which it is derived. Thus, in the original rock formation, we have the substances in their crystalline state. By the action of weathering these become broken down, and gradually washed away by the rain and carried into the embouchures of the rivers wherein they are deposited. As the rapidity of the current decreases, first the heavier particles fall, and these form the sands; then the next form the lighter sands and loams; and as the rapidity of movement of the water decreases still further, the almost impalpable fine particles settle and form the clay beds. Thus it is evident that the character of the various deposits will give a true indication of the kind of rock from which they were originally derived. Thus the granite rocks produce a sand the principal ingredients in which are quartz, felspar, and mica. The volcanic rocks are represented by sands, in which lava, obsidian, &c., appear. The flat, soft-grained sands arise from the disintegration of the schistose rocks; the calcareous rocks, as might be expected from their soft nature, are those which are least represented in the series, unless in the case of the siliceous sands arising from the comminution of the flints so plentiful in some of the secondary formations.

The mineralogical characteristics of these substances are of considerable interest, and their appearance under microscopical examination will tend to show their specific differences in a very clear light. Mica in thin plates, some colourless, some dark colour, and some green.

Quartz sand is made up either of entire crystals or of fragments of crystals, so that each particular grain has one certain optical structure. A grain of quartz sand examined by polarised light under the microscope will appear to be black when the two prisms of the polariscope and the grain of quartz are in a certain position to one another. It is not shown on the field of the microscope, because the axes of depolarisation are parallel. As the quartz is rotated on its axes, without the prisms being altered in their position, it becomes brilliantly illuminated and coloured with all the prismatic colours, and as the rotation is continued these subside and the quartz is once more in darkness; and this alternation of brilliant illumination and invisible darkness continues as the continued rotation brings the axes of polarisation parallel or not with that of the prisms of the polariscope.

Flint is made up of a great many very small crystals, and when it is seen in polarised light it looks mottled. The difference between the two is the difference between a great bit of granite and a piece of coloured glass. On the whole, the flint would look mottled, with black and white all over. The bright colours are not seen, because the size of the individual crystals is not sufficiently great to produce interference of a high order to give any colour. In a hundred grains or so one might be met with which would cause doubt, but the differences between the quartz sand and flint sand is as well marked as the difference between sheep and goats (Sorby).

Sand.—We may now consider the sands in much the same way as that in which we have glanced at the clays. Next to oxygen silicon is the most abundantly-occurring and widely-diffused element known. It does not occur in a free state, but always in combination with oxygen, thus (SiO_2) or silica, as mentioned above, which substance either alone or in combination with various metals, forms an immense series of well-known and widely-distributed minerals, the following being some of the natural forms in which it is found:—

Natural Forms of Silica (SiO_2).

Quartz, or rock crystal.	Opal.
Amethyst.	Jasper.
Agate.	Flints.
Chalcedony.	Sand.
Onyx.	Sandstone.
Cornelian.	Infusorial earth.

The quartz and amethyst occur in well-shaped crystals belonging to the hexagonal system (six-sided prisms), agate and chalcedony are a mixture of crystallised and amorphous silica. The following compounds of silica are broadly classed as aluminic and magnesic silicates; but they mostly contain, in addition to these elements, sodium, potassium, calcium, iron, manganese, &c. Their chemical

formulæ are very varied and complicated, and by no means thoroughly known :—

SOME COMMON SILICATES.

Aluminic Silicates.	*Magnesic Silicates.*
Beryl.	Asbestos.
Clay.	Augite.
Felspar.	Hornblende.
Garnet.	Meerschaum.
Jade.	Olivine.
Lapus lazuli.	Stéatite (French chalk, soap-stone, &c.).
Mica.	
Pumice stone.	Talc.
Slate.	
Topaz.	

Technically, sand is known as "argillaceous," "siliceous," or "calcareous," according to its composition, and is procured from pits, rivers, sea shores, or by grinding sandstones. Pit sand has an angular grain and a rough surface, which is admirably adapted for mortar; but it often contains clay, and similar impurities. River sand is not so sharp or angular in its character, the grain having its points rounded and polished by attrition. It is commonly fine and white. Sea sand, for the same reason, is also deficient in sharpness, and it contains alkaline salts, and is said to cause permanent damp and efflorescence, or "saltpetreing," as it is termed.

In those deposits caused by rivers which have long ceased to flow, the sand is known under the name of "pit sand," to distinguish it from that borne down by the rivers called "river sand," and from "virgin sand," which remains in the place where it was formed. Pit sand is generally of a sharper and more angular grain than river sand; but in all other respects its composition is identical, excepting that it is occasionally stained by ochres or clays containing oxide of iron in more or less abundance.

The generally-received opinion that sand should be perfectly free from all earthy matters is only true to a certain extent. There exists a species of sand in very large masses in France, where it forms even entire hills, consisting of comminuted chalk in irregular grains, very unequal in size, and mingled with a clay, sometimes yellow, red, brown, or even white, in proportions varying from a quarter to three-quarters of the total volume. It is known under the name of "arcues," and is largely used in conjunction with the rich loam from river and waterworks. Some of the decomposed Granwacke rocks also yield an argillaceous sand, composed of quartz, schiste, felspar, and particles of mica, agglutinated by a species of clay, which is very valuable, whether used in its natural state or calcined to make artificial puzzolanos, like Arènes. The granite rocks of Devonshire, some parts of Brittany, and of the extreme North-West of Spain, all of which are characterised by a remarkable excess of felspar, yield a sand of great value for building purposes, especially when mortars composed of it are not immediately exposed to the effects of running water. In all probability the potash present in the decomposing felspar may influence, in the opinion of the late Mr. Burnell, the setting of the limes mixed with the sands thus obtained.

READJUSTMENT OF DISTRICTS.

By EDWARD F. WILLOUGHBY, M.D., D.P.H.

FROM the small progress as yet made in the business already before Parliament it seems highly probable that the Bill for the better government of London may not be even introduced during the present session, and should this be the case the mention of it in the Queen's Speech was, to say the least, inopportune, coming as it did on the eve of the County Council elections, when conjectures and assumptions as to its aims and scope gave rise to much party feeling and mutual recrimination. The only intimations given by those to whom alone its provisions are known relate to the proposed incorporation of the larger and more important of the London districts as municipalities with the organisation and powers belonging to such elsewhere, in the hope that the enhanced dignity of the local parliaments will have the effect of raising their tone and of attracting candidates of higher education and social position than the average Vestryman. If this be all, the fate of the Bill is to us a matter of indifference. For, in the absence of any qualification and with practically universal suffrage, we fail to see the virtue of a mere change of name, while the electors will not enjoy the freedom of choice they have in nominating as candidates for the School Board and County Council men of mark from outside their own district.

The amalgamation of the smaller districts, or their absorption in the larger, has been suggested as a corollary of the creation of municipalities, and is, to our mind, a matter of far greater urgency; but with it we should like to see a general reduction in the number of the representatives, as likely to do much towards making these assemblies more worthy of respect. But whether the new districts be more or fewer than at present, a readjustment of their boundaries is imperative in the interests of public health and effective administration. Save in inequality of area, population, and value, such parishes as Hackney, Islington, St. Pancras, Marylebone, Paddington, and Kensington are well enough; but while many in the East and South are too small, and, from the character of the population, are unfitted for self-government, the boundaries of a number in the W.C. and southern districts, are the reverse of "scientific," reminding one of the "dissected maps" that served for the instruction and amusement of our childhood. The way in which some—as the Strand, St. James', and St. Martin's-in-the-Fields—intersect and surround one another, the intrusion of the three or four detached portions of extra metropolitan South Hornsey within the metropolitan area, the fragments of Chelsea at Kensall Green, and of Kensington in Chelsea, on the banks of the Thames, of Woolwich, on the north of the river, and of Clerkenwell far away in Hornsey, are simply ridiculous, and call for rectification by the strong hand of Parliament, since experience has shown in three, at least, of these instances, the futility of Local Government Board inquiries in the face of local prejudice and imaginary vested interests.

Another boundary question is that of the detached portions of counties, the most conspicuous example of which is furnished by Worcestershire, of which

about a dozen isolated fragments are scattered over the adjacent parts of Gloucestershire and Warwickshire, so that in a twenty-mile ride from Chipping Norton to Evesham, or from Stratford-on-Avon to Winchcomb, one might cross and re-cross the boundaries of Worcestershire several times in the hour. These islets are purely rural in character, they do not contain a single actual or potential centre of industry, and whatever the historical explanation of their origin, there can be no conceivable pretext for the preservation of this anomaly, while its continued existence cannot but present impediments in the way of effective administration; and we do not see what there is to prevent their absorption into the county within which they lie, an area of like character and equal rateable value contiguous to and preferably on some irregular part of the boundary being ceded in exchange.

Then there is the unfortunate difference between the sanitary and the registration districts into which the country is divided, and which seriously interferes with the main end and aim of registration, viz., the employment of statistics of population, births and deaths, for the purpose of gauging the public health. But the readjustment of the registration districts in accordance with those of the municipal and sanitary areas would involve no fiscal changes whatever. It would indeed interfere with comparisons between the past and future statistics of the districts concerned; but this would be once for all, whereas the inconvenience consequent on the inclusion of parts of a rural district within a city, or of the city in the adjoining rural district, involves a perpetual source of embarrassment to the statistician.

NOTES ON
PRACTICAL SANITARY SCIENCE.

By WILLIAM H. MAXWELL.

No. 58.—REFUSE DESTRUCTORS.

(*Continued from page* 418.)

Boulnois' and Brodie's Improved Charging Apparatus.—This invention has been successfully introduced as a labour-saving apparatus at the refuse destructor at Liverpool, and other places. It is illustrated in Fig. 31, and is shortly described as follows:—

This invention reduces the manual labour of charging to a minimum, regulates the charge, and lessens the possibility of nuisance or offence.

The apparatus consists of a wrought iron truck, 5ft. in width by 3ft. in depth, and of such length as will cause it to be of sufficient capacity to hold not less than twelve hours' supply for the two cells which it commands. This truck moves along a pair of rails laid across the top of the destructor, and is capable of being worked by one man. The truck is divided into compartments holding a charge in each, and provided with a pair of doors in the bottom opening downwards, which are supported by a series of small wheels running on a central rail. A special feeding opening in the reverberatory arch of the cell of the full width of the truck (5ft.), and placed immediately over the drying hearth, is constructed by a fire-brick arch fitted into a frame capable of being moved backwards and forwards by means of a lever arrangement.

The truck when empty is brought under the tipping platform, and the carts tip their contents directly into it, and when it is required to feed one of the cells the truck is moved along so that one of the divisions is immediately above the feeding opening, and the wheel holding up the bottom doors rests upon the central rail, which is continued over the movable covering arch. Then the movable arch, actuated by the lever, is rolled back, releasing the doors and discharging the contents into the cell, so that no handling of the refuse is required from tipping to feeding.

This arrangement provides portable storage for a large quantity of material, and entirely does away with the necessity for the shovelling and handling, which is not only very objectionable from a sanitary point of view, but also adds to the cost of destruction.

Writing upon the charging apparatus as installed at the Liverpool destructors, the City Engineer says,[142] "One of the many advantages claimed for the tank arrangement is that unlimited storage capacity can be provided, which is not the case in any other destructor; and it has been proved that a considerable saving in cost is effected by the introduction of the tanks."

This special form of cell also allows the gases and products of combustion to be drawn off evenly over the level bridge at the back of the cell, instead of at one corner, as in the ordinary Fryer's cell, and the application of these tanks and movable charging openings can be made to any form of cell now in use.

Fire-bars.—In addition to the ordinary type of stationary fire-bar, there are several kinds of patent movable bars used in connection with destructor furnaces, although these are, as a rule, found to be of but doubtful advantage over the simple stationary type. Amongst the movable bars are the following:—

Settle's Patent Grate Bar[143] is illustrated in Fig. 32, from which it will be seen that a pivot is placed near one edge of each bar, so that they tilt upwards only in one direction, either forwards or backwards, as may be required. The bars are connected to rods, actuated by means of a hand lever, so that the movement of one rod tilts all the even bars and the movement of the other rod tilts all the odd bars. The even and odd bars can therefore be tilted alternately either by hand or automatically.

Each bar when tilted throws its fuel on to the next bar in succession, and, as the odd and even bars work alternately, whilst the intermediate bars remain stationary, the bars act as "carriers" as well as "rockers," and thus convey the clinkers and fuel either towards the bridge or towards the furnace doors as may be required, according to whether the bars are fixed with the pivots to the back edge or to the front. In the former case fuel fed on to the bars nearest the dead-plate will be gradually carried towards the bridge.

Vicars' Grate Bars[144] impart a forward motion to the fuel or refuse, and are actuated by machinery from a cam shaft.

Biddle's Rocking Bars,[145] Fig. 33. The fire-grate consists of a series of bars, of which each alternate

one is made to rock as shown in the diagram. A, stationary bar; A^1, rocking bar; C, a transverse rod upon which A and A^1 take a bearing centrally. The stationary bars A at each end take a bearing on the stops or lugs D, whilst the rocking bars can be moved at and through varying speeds and spaces. The bars are actuated by means of a lever B^1, connected through link E to the inclined rod B bearing the member B^2, which acts upon the bars as shown.

Horsfall's Self-feeding Apparatus.[146]—In one of Horsfall's "improved type" furnaces, at the bottom of the refuse hopper, there is a series of sliding plates, or "pushers," adapted to force the refuse forward on to the grate bars, which are of the moving or rocking type; and are usually constructed according to Settle's patent. The "pushers" extend the whole width of the furnace, and they are operated by means of eccentrics through eccentric straps and rods, the shaft on which the said eccentrics are mounted being rotated slowly from any suitable source of power. On the same shaft are also mounted cams, adapted to operate levers actuating the moving or rocking grate bars, through suitable links or rods. By the use of these pushers and moving or rocking grate bars, the refuse and clinker are gradually moved forward, so that the ashes and clinker are deposited on the front dead plate, from which they are removed at intervals through the furnace door.

Healey's Movable Bars.[147]—These are forwarding motion bars, fixed as shown in the illustration of Healey's furnace (Fig. 11), and are constructed as illustrated in the accompanying diagram (Fig. 34). Above the fire grate bars, which are fixed level, are small inclined feeding bars, the feet of which take their bearings in toggle or knuckle joints on the fire-grate bars. At the upper end of the inclined bars is a long box casting or carrier, in which the upper or fixed feed bars can expand, and the moving feed bars can reciprocate.

Healey's feeding and fire-grate gear is applicable to all kinds of furnaces in which refuse fuel is burnt, and his patent extends to the gearing of the motor[148] which drives the cam shaft for operating the bars.

(To be continued.)

THE SANITATION OF DOMESTIC BUILDINGS.

By Frank Latham, C.E., M. San. Inst., &c., Assistant Surveyor, Borough of Margate.

CHAPTER VII.

DRAIN TESTING.

Among the various descriptions of apparatus for the purposes of producing and applying the smoke for this test are the "Eclipse" drain-testing machine, the "Asphyxiator," Jones' patent, and the "Grahtryx," which are recommended for general use. The former (Fig. 90) is made by Messrs. Burn Brothers, and consists of a copper chamber containing the smoke-producing substance. Communicating with this chamber is a double-action bellows, by means of which the smoke is propelled and generated. An advantage in the use of this apparatus is that upon the tube of the chamber being applied to the drain, and all vents closed, should the cover of the chamber which is water sealed while the machine is actuated, become raised, and remain so, it will prove that the drain is air-tight.

The "Asphyxiator" (Fig. 91), made by Messrs. J. Watts and Co., consists of a combustion chamber containing the smoke-producing substance. This substance is kept alight, and the smoke therefrom discharged into the drain through

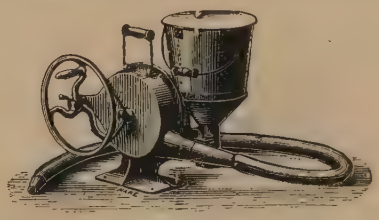

Fig. 91.

a flexible tube, by means of a revolving fan worked by a handle.

Jones' patent rotary-action smoke-generating machine (Fig. 92) is another good and compact tester, and is worked somewhat in the same manner as the "Asphyxiator," but is a later invention, the tubes being made with unions to fit Jones' patent drain stoppers. The

Fig. 94.

"Grahtryx" smoke machine, which is also an efficient tester. One of the best and strongest smelling substances used in the combustion chambers of smoke-testing machines is lighted oily engine waste or a mixture of sulphur and shavings. Smoke rockets (Fig. 94) such as Brock and Co.'s, Pain's, or Burnett's, which upon being lighted throw off thick volumes of sulphurous

Fig. 95.

Fig. 96.

fumes, are very useful and handy as drain testers.

After stopping up the vent pipes, three or four of these rockets should be placed in the lowest part of the drain, the fuse part foremost, and properly lighted, a stopper being immediately inserted in the opening in the drain.

Where the ordinary air inlet boxes are attached to drains the rockets can be lowered down the inlet pipe by a piece of cord, and when they have finished burning the stopper and rocket cases can be removed, and two buckets full of water discharged quickly down the pipe, which will drive

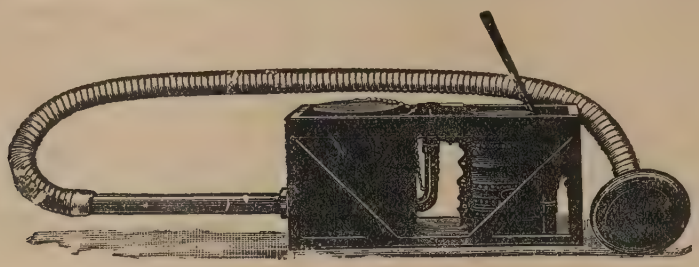

Fig. 90.

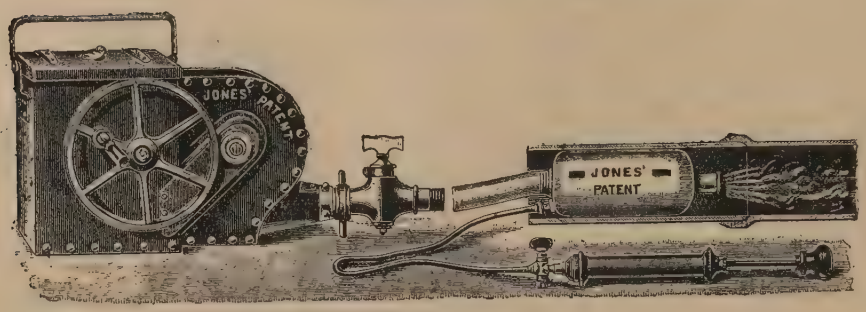

Fig. 92

the smoke through the drains. It is often necessary in using smoke rockets to open the outlet and inlet pipes for a short time to admit air before the smoke will pass through the drains.

Burnett's patent smoke tester (Fig. 95) is a satisfactory and convenient arrangement, it being on the same principle as the rocket, but can be inserted into the drain through the water of either a gully or water-closet trap. This is done with the assistance of a detachable wire handle, by which, upon the match being properly ignited, the tester is thrust through the water and the drain charged with a large volume of dark pungent smoke.

Smell tests for drains are sometimes used, more especially for testing the soundness of water-closets and other internal connections. The best for this purpose are chemical ones, the substance being packed ready for use in small air-tight tin spring boxes bound round with a long length of string (Fig. 96). The string upon being partly unwound and the end held, the tin box is placed in the trap and flushed into the drains, warm water being best for this purpose, which will unwind the remaining string, whereupon the contents of the box escapes into the drain, and throws off a very powerful and peculiar odour, which soon finds its way through any leaky joints or fractures and is easily detected. Some of the best of these are Kingzett's and the Sanitas Company's Improved, Burnett's patent, and Kemp's patent, all of which the writer finds to act very successfully

---

Perth Consumptive Hospital.—New buildings are to be erected in connection with the Hillside Home, Perth. They comprise a men's hospital, a women's hospital, and an administrative block—all to be devoted exclusively to the treatment of consumptive patients. There are three blocks, the centre one being the administrative block, which contains kitchen, sculleries, store-room, larder, pantry, &c.

"PRACTICAL SMOKE PREVENTION."

By W. Nicholson, Smoke Inspector, Sheffield.

(*Concluded from page* 450.)

WHAT KIND OF FURNACES ARE WE SPEAKING ABOUT?

When we say heating furnaces it embraces many furnaces, very large and small, plate, guns, ingot, billet, ball, tire, axle, spring, sheet, air, annealing, hardening, and many other kinds of furnaces known by special names, almost numberless, but yet coming under the head of heating furnace.

There are three exceptions which we desire to take from this list, viz., thin sheet steel, annealing, and hardening furnaces, which are peculiar furnaces requiring little heat, smoke also, experienced men say, and much care in the working of them. Men who have worked this class of furnace between twenty and thirty years say, "The smoke gives temper and toughness to the steel, and without it the steel is unsuitable for the purpose required." This refers more especially to sheet mill furnaces. Even under these difficult conditions, the nuisance of black smoke can be reduced somewhat by having chimneys 80ft. high, and not 20ft., as the common custom is to-day. The draught difficulty could easily be overcome by having a separate damper for each furnace.

The special class of furnaces which we consider must be excepted will not at the very most reach 10 per cent. of the whole. Supposing we say 10 per cent., then there is 90 per cent. of the furnaces which can be dealt with, and from which, at the least, between 70 per cent. and 80 per cent. of smoke emitted could be practically prevented. I know many will say that is a very large order—smells of America—and is easily put on paper, but not so easy in practice.

HOW CAN IT BE DONE?

Some say by substituting gas. To work by gas will prevent the smoke, but to put down a gas

plant is very costly, and costly to work, especially if the furnaces are not required night and day; the producers are consuming coal all the time, wages paid, and many other items; but the greatest cost would be the reconstruction of all the furnaces, which would mean bankruptcy for many. So gas for the working of heating furnaces is suitable and successful in some cases, but is not in others, owing to the great cost and other impracticable things which prevent it from universal adoption.

FURNACE CHIMNEYS RAISED.

Many of the manufacturers are now discharging smoke from furnaces into their tall chimneys, which considerably minimises the nuisance, but the large majority of furnaces have very low chimneys. They ought to be raised considerably, the results would prove very satisfactory both to the manufacturer, the man who works the furnace, and from a public health point of view.

Most of the smoke can be practically prevented by sensible stoking. The present system of firing furnaces:—(1) They put on about three times more coal than they ought, to make it last. (2) They make up the door, or hole if there is no door, and thus exclude all air. (3) Anybody and everybody—lads often—fire the furnaces, with no knowledge or care in firing. With such senseless stoking we do not wonder at the volumes of smoke emitted. One man ought to be responsible for the firing of the furnaces, as men are responsible for the stoking of so many boilers, and should be made by strict supervision to prevent as far as practicable all black smoke. This can be done by carrying out the simple suggestion or rules laid down in this paper for the firing of boilers, which are four in number:—(1) Firing lightly; (2) firing oftener; (3) admitting the necessary air to the furnace; and (4) shutting it off when not necessary. Furnaces can be worked by these rules; in other words, by the same sensible stoking as boilers, with the same, or nearly so, satisfactory results. This is not simply speculation, but has been proved by experience in the working of these furnaces. I could give many instances, but three will suffice.

A man in one of our large firms had charge of a number of heating furnaces which were very large. The man whom he succeeded allowed the men under him to fire in their own slipshod fashion, but this man in question, being a thoughtful person, determined to fire the furnaces on a more scientific system, which was as follows:—Lighter fires, admitting a little air to cause combustion; and he told me "the results were most satisfactory." They got their heats hot quicker, consumed considerably less coal, and made very little smoke, which system, he said, only cost a little extra labour to the men.

ANNEALING FURNACES.

There are some annealing furnaces so constructed that the wire or special steel to be annealed is placed in boxes, or in other ways protected from the flame of the furnace. In this class of annealing furnace a dense black smoke can be practically prevented. We have often pointed this out to the men in charge, who have never attempted it, or even thought about it; and working on those suggestions, they have done more work with the furnace, and prevented those long and black emissions of smoke.

AIR FURNACES.

A class of furnace used for the melting of large lumps of metal. One day I saw a chimney belching forth black smoke for twenty minutes, without any cessation, and went into the works to inquire the cause. In company with the manager we found it was an air furnace. The man in charge had worked that furnace more than twenty years. He always put a very heavy fire on, and shut the door tightly, to keep out every bit of air. He was one of those men whose knowledge about working of air furnaces was perfect, and resented being taught by his manager or anybody else. He was told to fire lighter, admitting a little air, which he did; and was surprised at the result—no interference with the working of the furnace, increased heat, and very little black smoke.

I feel sure, with such practical demonstrations, the reader will agree with me that much can be done to practically prevent black smoke from heating furnaces.

If it were necessary I could give many more instances which are practical proofs that much of the dense black smoke from furnaces can be prevented by the application of a little common sense in firing, which only means a little extra labour on the part of the men in charge; but this is unnecessary, assured that sufficient has been said to satisfy the most sceptical on this point.

RESULT WILL BE RICHES.

In all our experiments and experiences we want the result to be riches—gain in some way or other. If we had no such policy or prospect, I feel sure we should seldom enter on the expedition. Most writers on this question have dealt very extensively on the blessings and benefits to be derived from the abolition of black smoke, so there is no necessity to cover the same ground as they; but just, in conclusion, let me draw attention to the public and personal benefits which will be obtained if the few practical and simple suggestions as set forth in this article be carried out in the working of boilers and furnaces.

(1) *Public health.*—The rich, after business hours, can leave the smoke-laden atmosphere, and go to pleasanter parts where the atmosphere is more bracing and beneficial. The poor man's lot is quite different. He is compelled to live near the large works, and in an atmosphere which is not healthy, so, on the ground of public health only, everything ought to be done that is practicable to make the air pure. But we must not forget that the working men, who are the greatest sufferers, have largely the remedy in their own hands, as they are the smoke makers, or can be the smoke preventers.

(2) *Personal health.*—This is a personal matter, and concerns everyone, because a man's health, in many instances, is his only wealth; so looking at the question from a selfish point of view, it behoves every man to play his part.

(3) *Financial benefits.*—The other benefits named may be considered indirect benefits, but there is also, beyond all question of doubt, a direct saving by practical smoke prevention, as many manufacturers have proved and are prepared to prove. This fact alone ought to be enough to make all concerned do their best in this matter to benefit themselves.

(1) *Cleanliness.*—There is no question about cleanliness by a diminution of black smoke. We

are all agreed that with less smoke there will be less dirt, less defacement of public and private buildings, less darkness, less washing and cleaning for the housewife, more sunshine, more pure air, and more pleasant surroundings.

This is no wandering of the imagination but what actually takes place when the pall of smoke is removed. Cleanliness, it is said, is next to godliness, and godliness is goodness, so if we desire to be good we must have cleanliness, and must procure it as far as practicable by preventing black smoke.

Black smoke does not end with dirt, it produces disease of a moral kind. I know many will say we are now plunging into the sea of sentimentalism, and making smoke responsible for things which it cannot produce; but let us look at the matter a little closer, and we shall find that many of the moral maladies are the creations or children of dirt.

How are these ailments of loss of life brought about? By dirt. It being continuous, they lose all spirit in trying to keep the house and the body clean; they become more dirty as days go on until they lose all sense of cleanliness, decency, and dignity of life; they become debased and demoralised; this demoralisation being contagious, it spreads rapidly, until all neighbourhoods are infected by it, which results in death to all that is good, great, and noble. Tracing it to its source, we are compelled to confess that black smoke or dirt is largely liable for some of the moral maladies humanity suffers from to-day.

If we desire a better moral tone, we must make the surroundings (where the great bulk of the people live) more sanitary and more smokeless. This is an individual work; every man must play his part by emitting as little dense smoke as possible from his own house chimney, helping and urging others who are in charge of boilers and furnaces to do the same. Then by one united action this great smoke-nuisance question will be solved, life will be more pleasant and profitable, and the solution will confer innumerable benefits and blessings on the world at large.

A SANITARY DRINKING FOUNTAIN.

DRINKING cups have been long recognised as a probable means of spreading diphtheria and other contagious diseases affecting the mouth and lips. In summing up the results of the medical inspection of the New York city schools for the quarter ending June 30th, 1897, the *Sanitarian* showed that of the 4183 children excluded from the public schools on account of sickness during that quarter, 265 were for diseases liable to be communicated by the use of the common drinking cup—diphtheria, croup, scarlet fever, whooping-cough, and mumps. Of other diseases, more or less liable to be spread by the same means, there were: cases of measles, 51; chicken-pox, 93; and contagious diseases of the eyes, 702.

In the same relation to adults—to all who use them—are the drinking cups and tumblers common to public places; railway stations, street drinking fountains, manufacturing establishments, &c., where persons afflicted with consumption, scrofulous and syphillitic diseases of the mouth and lips indiscriminately use such cups and glasses! The mere statement of the practice suggests its danger. And so, too, the railway drinking cups and glasses, which should be avoided as much as possible.

The drinking fountain illustrated herewith is an ingenious device recently invented by a citizen of Rochester, N.Y., which wholly supplants the use of cups and other drinking vessels in public places. It consists of a marble pedestal about 3½ft. high, capped with a funnel-shaped basin 12in. in diameter,

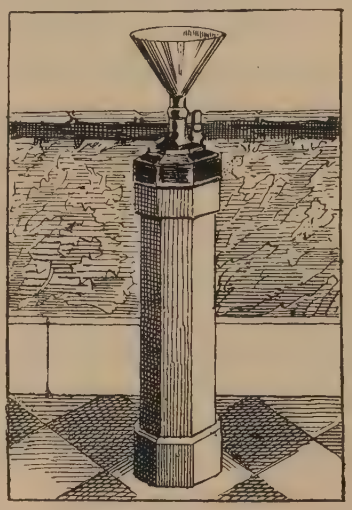

Fig. 1.

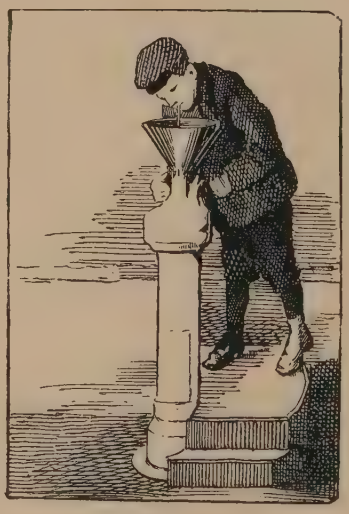

Fig. 2.

connected with the water supply. Upon pressure of a lever at the base of the basin a jet of water shoots up from the centre of the basin and into the mouth when held over, and from this—the jet being small and without spatter—with very little tact thirst may be abundantly satisfied without the intervention of a drinking vessel of any kind. It admits of no contact of the lips with the jet pipe or any other portion of the apparatus—the water flows from the supply pipe through the jet directly into the mouth; and all waste into the bowl im-

mediately flows off by an escape pipe—none is allowed to accumulate.

The fountain is highly commended by the Health Officer and members of the Board of Health of Rochester, and others who have examined it. A movement is on foot to have it placed in all the public schools of the city. One has been placed on the first floor of the City Hall, and measures are in process for setting it up in other public places. Accepting the testimony of the Health Authorities of Rochester, the "Drinking Fountain" is a pre-eminently clean thing in a strict sanitary sense. The adoption of such a fountain in the public schools and in other public places provided with water supply in this country is well deserving the attention of an enterprising manufacturer.

WATER SUPPLIES IN RURAL DISTRICTS.

By Dr. M. J. OLIVER, Medical Officer of Health, County of Roxburgh.

THE difficulty of finding water for farms and houses is in many parts of the country very great, and there can be no doubt that these difficulties will become greater unless the methods of dealing with supplies at present followed by proprietors and their agents are altered. From many conversations on the subject, I gather that it is a prevalent idea that if the supply of a farm be impure, and a spring welling up from the depths of the earth cannot be found within a short distance of the farm, it is impossible to obtain a pure supply, and the Local Sanitary Authority must allow the use of an impure water to be continued.

To a certain extent the difficulties in maintaining the purity of supplies, and in finding new ones, arise from neglect of the conditions which must be observed, having regard to the nature of the sources of water available in this district. Owing to the geological formation of the country, deep springs are very rare, but small collections of water occur freely among the superficial clay beds and in the deposits of gravel by the streams. The deeper rocks are generally waterless, consisting as they do in a very large part of the district of porphyry, fissured and pervious.

The available sources are, then, either surface or subsoil water, and in cultivated land the former cannot be used on account of pollution from farming operations. Whether the water is brought to a farm by gravitation, or is obtained from wells in the vicinity, the source of the water is the same—the subsoil—the source being in one case on high ground at a distance, and in the other in low ground, and near. The conditions to be observed, if pure water is to be obtained, are the same in both cases and the chief condition is that the fountain-heads or wells must be efficiently protected against the entry of surface water from cultivated land.

When we look at the customary method of doing this, we find that it is not calculated to effect the desired object. When a spring is found, the ground is usually excavated to a depth of from 4ft. or 5ft. to 8ft. or 10ft., the water is conducted in land tiles to a large tank constructed of bricks and cement, and from there in close-jointed iron pipes to the farm. As soon as the operation is completed the land over the sources is ploughed and manured in the ordinary routine of farming. In other instances, wells are sunk in arable land or close to farmsteadings and houses; the lining is of stone, with perhaps 2ft. or 3ft. of puddle clay at the top; and when a stone or wood cover has been fixed the soil is replaced, and the ground cultivated and manured as usual.

On action being taken by the Sanitary Authority, the proprietor says the farmer should not have manured the ground near the fountain-head or well; while the farmer complains that he is not supplied with pure water, and maintains that he must manure and cultivate the ground he is paying rent for. All this can obviously be prevented by arrangement at the time of letting the farms. A clause in the lease would prevent any disagreement as to the right of proprietors or farmers; but in arranging the lease each of the parties is often disinclined to raise the question of water supply, the farmer knowing that he can at any time secure the interference of the Sanitary Authority, and the proprietor trusting that, as the water has been used for many years, its purity will not be questioned now.

It is known that if polluting matter, such as manure, is only occasionally applied to ground, that the surface water is sufficiently purified by percolating through about 10ft. of soil; and that, therefore, if the spring or fountain-head, the pipes or land tiles leading to it, and the pipes from it to the cement tank were all at more than 10ft. from the surface, it would be possible for the occasional application of farm manure to the land not to render the water unwholesome. These conditions are, however, very rarely found; if the tank or the springs be sufficiently deep, runners or leaders to the spring are nearly always to be found comparatively near the surface. In fact, it is probable that not in five hundred of the water supplies in this country have every part of the collecting apparatus at 10ft. from the surface.

In the case of wells this condition may be more easily obtained, as the sides may be puddled with clay to a depth of 10ft., or the well may be cemented over at that depth; but there may be difficulty in preventing leakage along the sides of the suction pipe, and there is difficulty in obtaining access if the well has to be opened for any reason. This, moreover, only protects from occasional pollution of the surface of the ground, and is of little value when the source of pollution is a leaking house-drain or a soil polluted by frequent additions of organic matter, as is frequently the case in the neighbourhood of houses.

It is evident, therefore, that depth is in many instances sufficient to ensure the purity of water, but the condition is not always to be obtained, and any old field drains in the neighbourhood, the existence of which has been overlooked, may render all precautions as to depth of no value.

When, however, the surface of the ground is guarded by a layer of good old turf there is little cause for doubts as to the purity of the sources below. Dr. Robertson, in the course of some experiments, found that vegetation interfered with the growth of the typhoid bacillus in soil. It is known that the roots of plants are surrounded by enormous numbers of nitrifying microbes. The plant roots ramify through the upper layers of the soil, and carry the microbes with them. The work of Dibdin and others has shown that these are the most

powerful agents we possess for purifying sewage, and the life of disease-producing bacilli is short when the soil is already occupied by a vigorous growth of the harmless species. It is therefore the case that a matted bed of turf roots is one of the most perfect filters, and the fact of land being covered with it adds enormously to the safety of waters derived from the soil beneath. The explanation may be only the outcome of recent investigations, but the fact that subsoil water from grass land is safe has long been recognised. The frequent recurrence of the names "Well-acre," "Well-park," &c., shows that our forefathers considered such an enclosure a necessary adjunct to the well. It is probable that many of these parks were only ploughed in the early part of this century, when every patch of ground fit for growing wheat was cultivated.

Reversion to the old practice of sinking wells in grass land would, with rare exceptions, prevent their pollution. In cases where there is no pasture in a suitable situation, it would surely, in these days when farmers are all anxious to reduce the labour bill, be possible to arrange to lay down a paddock in grass for the special purpose of protecting the well. Where gravitation supplies are introduced, and the sources are in arable land, the same treatment is necessary. It is, of course, necessary that a certain amount of discrimination be exercised in fixing on a site for a new well. It should be above, rather than below, the level of the farm buildings, and on the side of a farm distant from a stream rather than on the near side.

Unless such old-fashioned methods of obtaining pure water be adopted there is nothing short of such a scheme as that recently under the consideration of the Kelso District Committee—the proposal being that about forty miles of water mains should be laid to supply water to the fifty-five places mentioned in the County Sanitary Inspector's report as without proper supplies. This would mean a rate of 6d. per £ on the whole district; and if all the proprietors charged with the cost of the scheme desired to have the water brought within a reasonable distance the cost would be prohibitive. The large number of comparatively new wells or gravitation schemes, by which it is sought to find good water in the polluted soil near houses, or within a few feet of the surface of arable fields, shows that proprietors, or those on whom they are accustomed to rely for advice, absolutely fail to realise the conditions necessary for obtaining pure water, and they must materially alter their methods if the desired object is to be obtained at reasonable cost.

CALCUTTA.—A telegram has been received from the Relief Society at Calcutta which states that, despite the panic in consequence of the plague, a great meeting has just been held protesting against the Municipal Bill, which, depriving the elected Commissioners of their powers, vests them in an official chairman, and a Committee of twelve, where the elected Commissioners will be in a hopeless minority. The chairman, Rajah Binaykishna, said that the city's twenty-two years of self-government were doomed. The Bill was strongly condemned by the speakers, who appealed for English help. Sir James Woodburn was thanked for his generous plague policy.

SYSTEMS OF SEWAGE PURIFICATION.

THE following is a synopsis of the report of the special committee of the Manchester City Council appointed to visit various towns, and report as to the best method of dealing with the Manchester sewage:—

The Manchester main drainage scheme, which was approved by the City Council on April 7th, 1887, has been in process of construction since that date. On December 31st, 1896, the City Surveyor reported that the sewage of an area of 5888 acres, representing a population of 400,360 persons, had been connected with the new system, and that a volume of sewage amounting to 16 million gallons per day average normal flow had to be treated at the works at Davyhulme. On December 31st, 1897, it was computed that the area connected was 7250 acres, with a population of 512,500 persons, and the amount of sewage being dealt with is 20 million gallons per day.

The means of purification adopted at the works have not been of such an efficient character as to enable an effluent to be produced which was considered by the Joint Committee as fit to be put into the water of the Ship Canal. In consequence, proceedings against the Corporation were instituted at the County Police-court. On September 16th, 1896, an order was made in terms agreed upon to the effect that the Manchester Corporation undertook to do all the acts necessary to prevent pollution within twelve months' time.

The proposal subsequently made by the Rivers Committee was to construct a culvert to convey the effluent to the river Mersey at Randle's Sluices. This scheme was altered to putting the effluent into the river at Woolston Weir, and was sanctioned by the City Council on the 18th November, 1896, but was rejected at a meeting of owners and ratepayers on the 4th March, 1897. The Rivers Committee on the 5th April, 1897, decided to proceed with the construction of two bacterial filters of one acre each. The Council meeting on 5th May referred this back to the committee for further consideration. The Rivers Committee eventually made a recommendation to the Council of a culvert scheme for conveying the effluent from the precipitation tanks to the tidal estuary. This was approved at the Council Meeting on September 1st, 1897. On September 9th, 1897, the stipendiary magistrate at the County Police-court granted a further postponement until November 30th, 1897.

On October 6th, 1897, the City Council, by a vote of 71 to 3, resolved to promote a Bill in Parliament to construct a culvert to convey the effluent to Randle's Sluices. A similar proposal was negatived at a meeting of owners and ratepayers on September 24th, 1897, and a poll was demanded, and taken on October 30th, 1897. The result was that 49,069 ratepayers opposed the resolution, and 20,528 approved, and there being a majority of 28,541 against the proposal, the scheme was abandoned. The Town Clerk applied to the stipendiary on November 26th, 1897, for an extension of time to comply with the order of the Court made on September 16th, 1896.

This application was granted, and the summons was adjourned until the 25th day of March next,

the stipendiary stating that he would then expect from the Corporation some scheme that would deal with the sewage in a way satisfactory to the Joint Committee.

On November 2nd, 1897, the Rivers Committee resigned, and on November 24th the present Rivers Committee was constituted in its place. At its second meeting, held December 6th, 1897, it appointed a special committee, termed the Effluent Sub-committee. Their duties were to consider and report upon the best method of dealing with the Manchester sewage in order to produce a satisfactory effluent.

REPORT OF EFFLUENT SUB-COMMITTEE.

The Sub-committee at its first meeting agreed upon the following bases of inquiry:—(*a*) That the means of solving the sewage question of Manchester lay on the lines of purification; (*b*) that the practicability, cost, and efficiency of artificial filtration should have their first consideration; (*c*) that every known system of treatment should be fairly considered, and that certain places should be visited for that purpose; (*d*) that all information which would lead to greater efficiency in the precipitation process be obtained.

Your sub-committee have had numerous meetings and they have visited many places. A descriptive account of these visits, compiled by the City Surveyor, is now sent to each member of the Rivers Committee.

The Effluent Sub-committee have given their best consideration to every system and suggestion that has been brought before them. Over sixty different schemes and appliances, and about fifteen suggestions, have been fully considered. In some cases opportunity was afforded to persons to explain their schemes before the Sub-committee.

Visits to the works at Davyhulme have been made in order to familiarise your Sub-committee with the possibilities of adaptation and improvement, and also with the true nature of the difficulties to be overcome.

The Committee report that the following towns have been visited:—

London: The Northern Sewage Works of the London County Council at Barking.

Friern Barnet (Middlesex): The Sewage Works of the Friern Barnet District Council.

Sutton (Surrey): The Sewage Farm and Precipitation Works of Sutton Urban District Council.

Hendon: The Sewage Works of the Hendon Urban District Council at Hendon, Middlesex.

Chorley: The Sewage Works of the Chorley Corporation.

Oldham: The Sewage Works of the Oldham Corporation at Slack Valley.

Swinton: The Sewage Works of the Swinton and Pendlebury Urban District Council at Folly-lane.

Salford: The Sewage Works of the Salford Corporation at Weaste.

Glasgow: The Sewage Works of the Glasgow Corporation for the drainage of the portion of the city of Glasgow.

Accrington: The Sewage Works of the Accrington and Church Outfall Sewerage Board at Coppy Clough.

It will be within the recollection of the Council that in the years 1878—1895 deputations from the Rivers Committee visited various sewage works.

The Davyhulme (Manchester) Precipitation Works were completed, and the treatment of sewage by chemical precipitation commenced in December, 1893.

The quantity of sewage thus dealt with has gradually increased as the old sewers of the city have been connected up with the new intercepting system of sewers, until at the present time the sewage from upwards of 512,000 persons is intercepted, and treated at the Davyhulme Works. Soon after the works were opened it was found that large quantities of grit from the street surfaces, sand, crushed clinker, &c. &c., were washed down to the works, and deposited at the inlet ends of the precipitation tanks. This was especially noticeable in times of flood, when as much as 300 tons of this material were brought down within the twenty-four hours. A small catchpit 44ft. long and 6ft. deep were originally formed at the outlet to the main sewer at Davyhulme, but as no means were provided for cleansing this pit it was discontinued on the advice of Mr. James Mansergh, M.I.C.E., Consulting Engineer, who was called in to advise the Rivers Committee in the interval between the decease of the late City Surveyor and the appointment of the present officer. The cost of removing heavy material deposited in the precipitation tanks was found to be considerable, as it had to be barrowed by hand on temporary plank gangways to the north side of the tanks, and then deposited on the land of the Corporation. Consequently, the Rivers Committee instructed the City Surveyor to prepare plans for screening chambers, intercepting catchpits, &c., somewhat similar to those in use at the sewage works of the Sheffield Corporation. The contracts for these catchpits, with buildings and machinery for adding and mixing the chemicals, are now let, and the works are in progress, and may be expected to be completed within six months from this date.

The system of precipitation at first adopted by the Rivers Committee consisted of treatment with lime and alum cake. This treatment was discontinued on the recommendation of Sir Henry Roscoe, and treatment with lime and protosulphate of iron substituted. This treatment has been continued up to the present time.

The effluent from the tanks is, with the exception of a very small quantity, passed direct into the canal. A small quantity is treated on 26¼ acres of land filters. The filtration of the effluent in four small experimental filters is still continued, and the results are carefully recorded.

Chemical report.—The purification of the Manchester sewage should consist in the production of an effluent of such a character as will fulfil the following conditions. It should be:—First, free from suspended matter; secondly, practically neutral (*i.e.*, containing excess neither of acid nor alkali); thirdly, not liable to noxious decomposition.

The known methods employed for sewage purification may be classed under the following heads:—(*a*) Land irrigation, with or without previous treatment; (*b*) chemical precipitation and subsidence; (*c*) bacterial treatment, with or without previous chemical treatment; (*d*) the system known as the "Septic" system. The systems that were inquired into or examined by your Sub-Committee all fall into the one or the other of the above classifications.

LONDON OUTFALL WORKS.

On December 22nd, 1897, the deputation visited the Northern Outfall Works of the London County Council at Barking. They were accompanied from London by Mr. J. E. Worth, M.I.C.E., the District Engineer, and were met at Barking by Sir Alexander Binnie, the Chief Engineer of the London County Council, and Dr. F. Clowes, F.I.C., the Chemist to the Council.

The sewage of the whole of the County of London north of the Thames, together with some outside districts, having a total estimated population of 3,266,348, is treated at these works. The total expenditure on these Barking Outfall Works to the present time amounts to £514,980.

The following description of the works was kindly given to the deputation by Mr. J. E. Worth :—

There are thirteen precipitation channels, ranging in length from 860ft. to 1210ft., 30ft. in width, of a working depth of about 8ft. 6in., and capable of holding 20,315,925 gallons. These extend over an area of eleven acres, and are covered by brick arches. There are two openings to each channel from the main outfall sewers, regulated by hydraulic penstocks 7ft. by 6ft. The effluent from the above channels passes through the old reservoir, and out of the nine openings in it into the river. Any one of the precipitating channels can be shut off for cleansing purposes. There are also twelve sludge settling channels, each 140ft. long and 20ft. wide, capable of holding sludge to a depth of 13ft. These channels are for the purpose of further concentrating the solids in the rather liquid sludge. There are stores under them for receiving and storing the finally settled sludge to the extent of 20,000 tons, exclusive of that stored in the sewage settling channels, and by this means provision is made against foggy weather, when the sludge vessels may be delayed in discharging their cargoes. There are culverts or communications with the various precipitation channels and the sludge settling channels, also for conveying the sludge to the pumps, liquor stores, &c. There is also an engine-house with two boiler-houses, one on each side, together with a repairing shop. The engine-house contains four 8in. centrifugal pumps, with 27in. fans, each driven by a vertical inverted single-cylinder engine, capable of discharging five tons per minute. There are also two 12in. centrifugal pumps, with 36in. fans of the same type as the others, but with more powerful engines. These are for lifting the diluted sludge as run from the precipitation channels into the sludge settling channels, a maximum lift of 21ft. Two Murray chain pumps are provided for lifting thick sludge from the lower store into the suction well of the pumps, next to be described. There are four horizontal compound pumping engines, with 13in. high-pressure cylinders and 22½in. low-pressure cylinders, of 18in. stroke. The pumps are 13in. double-acting ram pumps, each rod being coupled to the tail rod of the steam cylinders. Each pump can discharge four tons of sludge per minute into the iron main leading to the jetty for loading the steamers. There are three liquor pumps of a similar type to those above mentioned, but with a 12in. high-pressure cylinder, 21in. low-pressure cylinder, and 18in stroke, the pump rams being 14in. in diameter. These were for pumping the liquor drawn from the settled sludge through a 14in. main to the liming station, but a not unimportant improvement has taken place in this respect—that of dealing with the liquor drawn off from the settled sludge separately from the main body of sewage into which it was formerly discharged at the liming station above described. This liquor, amounting to 1¼ million gallons daily, or approximately 1 per cent. of the daily flow of sewage, is now treated with 20 grains of lime and 10 grains of protosulphate of iron per gallon, which quickly precipitates the suspended matter and deodorises this black and filthy liquid. Two hydraulic engines and accumulators supply power for lifting the twenty-six penstocks in the precipitation channels. Steam is furnished by ten boilers 22ft. long and 6ft. in diameter, working at a pressure of 75 lb. per square inch. There are sluices for opening and closing the communications between the various chambers, and pipes and appliances for ventilating and flushing the several chambers; and also a lever-house, which contains the means for lowering the telescopic weirs in the precipitating channels. There is also a river-water settling pond, 218ft. by 155ft., for supplying water to the liming and iron-water stations.

The liming station, for the preparation of lime water for treating the sewage, includes lime stores, slaking floor, wash mills, pipes and troughs for conveying sewage water from the sewer to mix with the slaked lime; also six large lime-water mixing tanks, an engine and boiler-house, coal-shed, and chimney shaft, and two large iron tanks or reservoirs for lime water above the lime store. There are two 17in. centrifugal pumps, with a capacity of 22 tons per minute; the maximum lift is 40ft. Each pump is driven by its own tandem engine, having inverted cylinders, the high-pressure being 12in. and the low-pressure 22½in. in diameter, the stroke 14in., and the fan 4ft. 6in. in diameter, making 250 revolutions per minute. Each is supplied with a surface condenser. The boilers are steel, three in number, 25ft. long, 6ft. in diameter, working at a pressure of 75 lb. per square inch. These buildings are situated about half a mile from the precipitation channels.

(*To be continued.*)

THE LOCATION OF HOUSE CISTERNS AND A PLEA FOR THEIR ABOLITION.

By ALFRED EDWIN HARRIS, M.O.H., St. Mary, Islington.

IN past years the Public Health Department of St. Mary, Islington, have found it necessary to compel owners to remove the cisterns from improper positions, such as from beneath the floors of bedrooms as well as from the rooms themselves; from within water-closets, and in not a few cases from above these places; from wash-houses, where, of course, the water was liable to contamination from the fluff and dirt of the clothing; and occasionally from the staircase landings of tenement dwellings, where the supply from the tap was situated at the bottom of the house. In the last cases it was found that tenants habitually drew the water direct from the cisterns in pails or vessels whose cleanliness could not always be guaranteed. It is a matter of regret that statutory power does not exist to compel property owners, who let their houses in this manner, to supply one draw tap to each floor, so that tenants, if cleanly, may not be put to the great labour and inconvenience of con-

veying water upstairs, and if lazy and uncleanly, they may be deprived of their only excuse for such habits.

That the action of the Public Health Committee is right has been very clearly proved just recently by the discovery in a new house in Tollington Ward that the water cistern was placed by the builder in the servant's bedroom.

I would very much like to see all cisterns intended for the storage of water for domestic use altogether abolished when the constant supply has been laid on to all parts of the parish, for they will not then be really required, if the company do its duty with regard to mains that are not buried sufficiently deep, and therefore liable to be frozen. I have lived during my lifetime in four great towns which possessed a constant supply, and in none were these cisterns tolerated. In each it was compulsory on the water companies to give notice to householders, when, owing to repairs, it became necessary to cut off the water temporarily, so that they might make some arrangements to store a sufficient supply for a short period, generally for a few hours, rarely for a day, and I have never known any serious inconvenience to occur.

The time is now approaching when the public and their representatives should insist that London must be provided with a proper, efficient, and sufficient supply to meet its demands, and then the only excuse for the continued existence of these cisterns will have ceased. They are sometimes the cause of disease through their want of cleanliness, and are often death-traps for rats, mice, and insects. Indeed, it is not long since a case of enteric fever was reported to me by a provincial Medical Officer of Health, who wrote to inquire as to the state of affairs existing in the house in Islington from which the patient had just arrived in his town, and who, without doubt, contracted the disease in this parish. An examination of the water cistern discovered a putrid mouse.

A pure water supply is now looked upon as so necessary for the preservation of health that I am surprised at the toleration of a system which so readily lends itself to the pollution of that element which is the greatest necessity of life. In 1896 the New River Company supplied its customers for domestic purposes with a daily average of 28,474,737 gallons, representing 177 gallons per house and 24·48 gallons per head of the population, and it is melancholy to think that the great bulk of this water was more or less contaminated in storage cisterns before it was consumed.

A 3300 MILLION-GALLON RESERVOIR.

ABOUT 200 gentlemen interested in the London water supply visited Staines on Saturday to see the cutting of the first sod in the construction of a great new reservoir for which the New River, the West Middlesex, and the Grand Junction Companies are to be responsible. For this purpose they have formed a Joint Committee, with Mr. E. Boulnois, M.P., as chairman, and Sir J. Savory, M.P., as deputy chairman. In 1896 Parliament empowered the Committee to raise £1,000,000 in debenture stock, and to take from the Thames 100,000,000 gallons of water in every twenty-four hours, pumping it into the reservoir at Staines, whence it would be distributed to the three companies for conveyance to the metropolis.

According to the Act of last year but one, the Staines reservoir should only contain 2500 million gallons, but the Committee want it to hold 3300 millions, and are so confident that Parliament will this session sanction the extension that they have adopted plans for a lake of the larger size. Should they be justified the reservoir—it will practically be one, though it is spoken of as two—will be about a mile and a quarter long, with a width varying from five-eighths of a mile to more than seven-eighths. Such a fine sheet of water would add to the beauties of Staines, but it will only be visible from a balloon, for it will be enclosed by banks 21ft. to 35ft. high, guarded by inclinable iron fences. The water is to be taken from the Thames above Bell Weir, about a mile and a-half higher up than Staines. There will, of course, be pumping stations and about five miles of acqueduct, partly open and partly covered, the lower end being at Hampton. Mr. Walter Hunter and Mr. Reginald E. Middleton are the engineers, Messrs. John Aird and Sons the general contractors.

Very complete arrangements were made for the visitors on Saturday. They were carried from London to Staines in a special train of first-class coaches, from Staines to the nearest part of the ground in wagonettes, thence to the point where the ceremony was to take place in the contractors' railway train, whereof the trucks had been specially fitted with new seats. They were hospitably provided with an excellent lunch, and were sent back to London by the diverse conveyances in which they had come. It was Mr. Boulnois who cut the first sod, after Mr. Aird, M.P., had presented him with a gorgeous spade of ebony and silver. Amid laughter and cheers, Mr. Boulnois did his work with much energy, placing in the glittering ceremonial barrow not only the first sod, but many spadefuls of earth besides, and wheeling it all up and down a plank as if he were earning sixpence an hour. Among the gentlemen present were Sir T. G. Fardell, M.P., Mr. E. A. Goulding, M.P., Mr. H. Kimber, M.P., Sir William Marriott, Sir C. Gibbons, and Sir J. Whittaker Ellis.

MEETING OF MUNICIPAL ENGINEERS AT WIMBLEDON.

A DISTRICT meeting of the Incorporated Association of Municipal and County Engineers was held at Wimbledon on Saturday last, the 30th April. There was a large attendance of members, who were welcomed by the Chairman of the Wimbledon Urban District Council. Mr. Joseph Lobley, Vice-president, occupied the chair. After the re-election of Mr. G. B. Laffan, of Twickenham, as hon. district secretary, a paper on "Municipal Work at Wimbledon" was read by Mr. C. H. Cooper, engineer and surveyor to the Council. The population of Wimbledon is 38,000 as compared with 4654 in 1861. The streets are lit by oil lamps at a cost of £2 11s. 9d. per lamp per annum, as against a cost of £5 10s. which was demanded by the Gas Company, and which the late Local Board refused to accede to. Very shortly these lamps are to be supplied with electric light, a scheme being in course of progress under the superintendence of Mr. A. H. Preece, electrical engineer. The rate-

able value of the district is £230,000, and the general district rate is 3s. 2d. in the £ per annum.

The system of sewerage is the duplicate one, surface water and sewage sewers being provided, surface water from the backs of houses, however, being admitted into the sewage sewers. Sewage disposal is effected by broad irrigation and intermittent downward filtration on beds composed of burnt ballast, having a depth of about 3ft., the ballast, however, being covered with a layer of soil about 7in. in depth. One portion of the sewage is strained through a mechanical strainer formed of brick bats, and then passed over the farm. The major portion of the sewage flow is, however, first precipitated in settling tanks, chemicals to the extent of 4 grains of proto-sulphate of iron and 12 grains of lime per gallon being added to aid precipitation. The resulting sludge is manufactured into sludge cake at a cost of 2s. 0¼d. per ton of cake. About 100 tons being produced weekly, which has, however, no marketable value, and it is proposed to erect destructors in connection with the electric light station to consume both cake and house refuse. The area of the sewage farm under cultivation is 59¼ acres, the soil of which was originally stiff clay, but which has now, with the addition of domestic ashes (applied for a considerable number of years on the surface and ploughed into it) been converted into a fair soil.

The Council are at the present time constructing depôt accommodation for the stud of thirty-nine horses kept by them, and for cartsheds, workshops, store-rooms, &c., which are designed and being constructed most effectively, while plans have also been prepared for an isolation hospital for one hundred beds.

A paper on "The Wimbledon Electric Lighting Scheme," by Mr. A. H. Preece, Electrical Engineer to the Council, was also read, after which there was a short discussion, followed by inspection of the works, and later in the afternoon an inspection of the Conduit and Insulation Company's works, Summerstown, was made, where a paper on "Electric Wiring Practice" was read by Mr. S. H. Bathurst, M.I.E.E.

The system of back drainage, as adopted for terrace houses, was inspected, and also the method of testing drains, wherein it appears that the Council permit the construction of combined drains to receive the sewage of not more than six houses. Each house drain, however, is required to be disconnected from the common drain by a disconnecting trap fixed in a chamber 2ft. 3in. long by 2ft. wide, and at or near the head of the common drain a ventilating shaft is carried up above the roof of the adjacent dwelling at the cost of the owner. No drains are allowed to pass under dwelling-houses. The method of testing new drains is the hydraulic or water test, which is twice applied to every drain, viz., before the drains are covered up, and subsequently when the ground is filled in, this being adopted to ensure that the joints are not disturbed in filling in the trenches. In addition to this, the smoke test is applied after all the fittings have been connected to the drains and soil pipes.

At the conclusion of the proceedings, which were highly interesting throughout, votes of thanks were accorded to the Wimbledon Council for placing the offices at the disposal of the Association, to the readers of the papers, &c.

Sanitary Inspectors' Associations.

SOUTH WALES AND MONMOUTHSHIRE.

A MEETING of members of the above Association was held at the Council Chamber, Guildhall, Swansea (by kind permission of the Mayor), this being the second meeting of the session. There was a large attendance. The chair was taken by the President, Dr. W. Williams, M.A., M.D., D.P.H., Medical Officer of Health to the county of Glamorgan. The Mayor of Swansea (Mr. J. Aeron Thomas), Dr. Ebenezer Davies, Medical Officer of Health, Swansea; Dr. Tafford Mitchell, Medical Officer of Health, Gowerton; Dr. A. Lloyd Jones, Mumbles; Thomas Phillips, J.P., Swansea; Dr. Herbert Jones (treasurer); and Mr. J. Tony Thomas (secretary) being among those present.

On the motion of the PRESIDENT, Dr. Ebenezer Davies was elected an honorary member. In making the proposition the President said Dr. Davies had been Medical Officer at Swansea since 1865, and he was too well known throughout Wales to require any eulogistic mention that afternoon. Dr. Thomas, Nantymoel, was also elected an honorary member.

The following gentlemen were elected members: Messrs. D. M. Jenkins (Neath), W. P. Jones (Glyncorrwg), Rhys Davies (Brecon), Joseph Humphreys (Maesteg), M. Williams (Bridgend), and Stanley Brunn (Oystermouth).

The Mayor of Swansea was accorded a very hearty welcome when he entered the room. In response to an invitation from the PRESIDENT to speak,

His WORSHIP said, in support of the Superannuation Bill, if Sanitary Inspectors only discharged their important duties faithfully and fearlessly public opinion would see that they were not only well paid, but enabled to put sufficient aside to enable them to create a superannuation fund.

The SECRETARY read a lengthy report in reference to the effort made in the promotion of the Sanitary Inspectors' Superannuation Bill for 1898. Many Welsh Members of Parliament had been seen. Communications were proceeding with Sir W. Harcourt with a view to a deputation waiting upon the right hon. gentleman; indeed, he had himself written the Secretary that he would receive a deputation.

The PRESIDENT delivered a most interesting address, which was received with continued applause.

Excellent papers were read by Mr. LLEWELLYN DAVIES, Chief Sanitary Inspector, Swansea, on "House Drainage"; and by Mr. DAVID JENKINS, Chief Port Sanitary Inspector, Cardiff, on "Port Sanitary Work." Most instructive discussions followed the reading of both papers.

The usual votes of thanks concluded a most enthusiastic meeting.

The members had tea together at the Mackworth Hotel at the close.

GLOUCESTER.—The Town Council has decided to apply to the Local Government Board for power to borrow £15,000 for the proposed new infectious diseases hospitals.

ADULTERATION AT DUDLEY.

THE annual report of Mr. J. Brown, the Borough Inspector under the Food and Drugs Acts, contains some very interesting matter, as well as valuable information. He warns us, amongst other things, to avoid salicylic acid, and to see that we get soda water when we order it. Salicylic acid, it appears, is the main ingredient of many preservatives, and is simply death to digestion. Soda water, as a rule, is taken with a "drop o' summat" in it, but according to Mr. Brown, the British Pharmacopœia prescription for soda water makes it quite unsuitable for a beverage. Only a third of the amount of bi-carbonate of soda is necessary in a 10 oz. bottle for ordinary drinking purposes, and Mr. Brown rather significantly points out that mineral waters which are simply carbonated or aërated should be labelled and sold as such, and not as soda or potash water. Evidently it is possible for the harmless soda-water drinker to be deceived. The percentage of adulterated articles last year, however, is very satisfactory. The figure is 7·6 per cent. (including the doubtful samples), while the average for England and Wales is 9·2 per cent. That well-known infantile physic, paregoric, is apparently a very difficult article for the chemists. It must not be without opium, and it must not have too much. Of six samples of paregoric one was found to contain no opium, and the defendant was fined £1 and costs. The other five cases contained the full 40 grains of opium—a scheduled poison—and the sellers were called upon by the Pharmaceutical Society to pay £5 5s. each. Perhaps the most satisfactory thing about the report is that it shows that real attention is now being paid to the important matter of pure food and drinks.

HAMPSTEAD PUBLIC BATHS.

AN official inspection by the chairman and members of the Baths and Wash-house Committee of the Hampstead Vestry has just been made to the new administrative block of the public baths in Finchley-road. The old front portion of the baths, which included administrative block, seven slipper baths, and the superintendent's apartments, was pulled down in consequence of the carrying out of the Manchester, Sheffield, and Lincolnshire Railway works. The company paid the Vestry £8300 as compensation, and gave them a larger area of ground for re-building upon, the new area being 5056 square feet in place of 2000 square feet. The new front is built in the English Renaissance style of an early type, from the designs of Messrs. Spalding and Cross, of Cheapside, at a cost of £8995. The builder was Mr. T. Kingerlee, of Oxford. The new buildings include an entrance-hall, with central ticket-office leading to two entrances for men and women respectively, twenty-four slipper baths (in place of seven old ones), with enamelled slate divisions, superintendent's and clerks' offices, board-room, and waiting-room, and superintendent's apartments. The baths now include four swimming baths and a number of slipper baths. The old portion of the baths has been repaired and re-decorated throughout.

General News.

SOUTH GOVAN.—The building of a dust destructor is being advocated.

SHREWSBURY.—The Local Government Board has refused to sanction the loan for a new water supply.

LITTLEHAMPTON.—The Urban District Council has adopted a water supply scheme which will cost £10,717.

SHIPLEY.—The increased death-rate in Shipley last year is mainly attributed to the ravages of influenza.

WARMINSTER.—The Urban District Council has invited tenders for proposed swimming bath at Smallbrook Mill.

PATRICROFT.—At a public meeting called by the Eccles Ratepayers' Association a further extension of the hospital was agreed upon.

WALTHAMSTOW. — The Urban Council has resolved to apply for sanction to borrow £2238 to build a Coroner's court and mortuary.

WOLVERHAMPTON. — The Water Committee have recommended that a new service be laid at a cost of £150, the parties concerned to pay half this amount.

NEWMARKET.—The Urban District Council has approved conditionally plans for a new 12in. water main from the water company's reservoir to the pumping station.

BRIGHTON.—Another pumping station is to be provided for the waterworks, and tenders will be invited for the building and equipment of the same, and for the sinking of various shafts, &c.

CHESTER-LE-STREET.—The Guardians propose to borrow £250 in addition to the £850 already sanctioned by the Local Government Board for erection of isolation wards at the workhouse.

SCUNTHORPE.—The Local Government Board has sanctioned the borrowing of £5000 by the Urban District Council to commence boring operations for a water supply. The total cost is estimated at £16,000.

CHISWICK.—At the first meeting of the newly-elected Urban District Council it was stated that the contract had now been signed for the purchase of a site for an isolation hospital. The price for the three acres was £2000.

EPSOM. — The Urban District Council has received from the British Institute of Preventive Medicine the result of their analysis of a sample of the water supply, which showed that it was of excellent quality, and well adapted for drinking purposes.

LONDON.—A Select Committee of the House of Commons on Thursday, the 28th ult., began the consideration of the Southwark and Vauxhall Water Bill, the objects of which are to enable the company to acquire lands, construct additional works, and take additional water from the Thames. The company propose to construct new storage for 1,076,000,000 gallons of water.

PORTLAND.—The Urban District Council has decided to borrow a further sum of £7647 for the carrying out of a water supply for the island. This will bring the total loan up to £37,000.

NORWICH.—The new refuse destructor at New Mills erected by the Horsfall Furnace Syndicate, Limited, of Leeds, is now in full operation. The destructor supplies steam for sewage-pumping purposes.

BILLERICAY.—The Urban District Council has virtually come to terms with the Southend Waterworks Company, and has, therefore, decided not to pursue its opposition to the company's Bill in Parliament.

LEEDS.—The Corporation Sub-Sanitary (Hospitals) Committee has accepted the tender of Mr. John Robinson, of Kirkgate, for the painting of pavilions and other buildings recently erected in connection with the fever hospitals at Manston. The amount of the contract is £500.

WITHINGTON (LANCS).—The Clerk to the Urban District Council has received from the Local Government Board an intimation that the Authority sanctions the application of the District Council for power to borrow £5500 wherewith to purchase the Baguley Lodge estate as the site for an infectious diseases hospital.

ST. HELENS.—The large additions recently made to the St. Helens Borough Sanatorium, or fever hospital, at Peasley Cross were opened last week by the Mayor (Alderman Richard Pilkington). The Sanatorium was first opened on the 25th of April, 1882. It then consisted of an old house of seven rooms, and the average number of patients was from eight to sixteen per annum. The total cost of the extensions has been £6389, and the total sum spent on the Sanatorium since the purchase of the residence of Mr. Radcliffe has been £14,120. The new buildings, which have been erected by Messrs. Whittaker and Woods, of St. Helens, comprise a large pavilion, an observation block of two wards, and a large increase in the administrative block which has been the means of remedying the previously unsatisfactory accommodation for the nurses. The Sanatorium has now accommodation for seventy patients.

BRIGHTON.—The report of the Medical Officer of Health (Dr. A. Newsholme) for the year 1897 draws attention to the fact that the death-rate was lower in 1897 than in any preceding year, that there was an entire absence of small-pox, and adds: "The official administration of vaccination in Brighton is happily accompanied by much less friction than in most towns, and the percentage of successful vaccinations is much above the average." As to the deaths from alcoholism, Dr. Newsholme characterises alcohol as one of the chief causes of premature old age. The evil effects are very commonly produced by systematic indulgence that would by most be regarded as "moderate." Those who, while never becoming intoxicated, daily take a considerable amount of spirits (especially if taken apart from meals) are much more likely to suffer in health and prematurely break down than the labourer who may get drunk once a fortnight and be a teetotaler in the interval.

Personal.

DR. F. R. BLAXALL has been appointed bacteriologist to the Local Government Board.

MR. H. A. ENDSOR has been appointed surveyor for the rural district of St. Haiths (Norwich).

MR. R. WEDGE has resigned his position as Sanitary Inspector for the rural district of Cannock.

MR. W. C. WILLIAMS has been appointed a Public Analyst for the county borough of Bootle.

DR. J. BLACKLOCK has been appointed Medical Officer for the Brindle district of Chorley union.

MR. W. GARDNER has been appointed Medical Officer for the Nunney district of Frome union.

MR. G. ANDERSON has been appointed Medical Officer for the Swinefleet district of Goole union.

MR. H. M. MACGILL has been appointed Medical Officer for the Hartlepool district of the union.

MR. J. C. O'RAFFERTY has been appointed Medical Officer for the first district of Daventy union.

HUGH JONES, M.B., D.P.H., has been appointed Medical Officer of Health for the rural district of Dolgelly.

MR. N. DEEKS, jun., has been appointed Inspector of Nuisances for the rural district of Castle Bromwich.

MR. J. S. MELLISH has been appointed Medical Officer of Health for the Wells Port Sanitary Authority.

DR. BRADSHAW has been reappointed Borough Medical Officer for High Wycombe for a term of three years.

R. PARKHURST, M.B., has been reappointed Medical Officer of Health for the urban district of Long Sutton.

MR. J. S. MELLISH has been appointed Medical Officer of Health for the urban district of Wells-next-the-Sea.

MR. A. S. ROBINSON has been appointed Medical Officer for the Kirkleatham district of Gainsborough union.

MR. J. A. BUDGE, Leven, has been appointed Burgh Surveyor for Buckie in succession to Mr. Chisholm, transferred to Peterhead.

MR. C. DEVEREUX, M.B., B.C., L.R.C.P., has been appointed Medical Officer for the Tewkesbury sanitary district of the Tewkesbury union.

MR. KENNETH CAMERON, Sanitary Inspector of Aberdeen, has been the recipient recently of two marks of honour which testify to his standing in the sanitary profession. One is his nomination as president for the ensuing year of the Sanitary Inspectors' Association of Scotland, which holds its annual meeting in Perth toward the end of June. The other is an invitation to become vice-president of the Conference of Sanitary Inspectors at the annual congress of the Royal Institute of Public Health, which is to meet in Dublin this year. Mr. Cameron has accepted both offices.

THE appointment to the vacancy in the honorary hospital medical staff of the Ladies' Charity and Lying-in Hospital, Liverpool, has been conferred upon Mr. Alexander Stookes, M.B., C.M., L.R.C.S. (Edin.).

Sewerage Schemes.

[TO MUNICIPAL ENGINEERS AND SURVEYORS.—The Editor will be pleased to receive items for publication relating to sewerage schemes projected or inaugurated, together with explanatory diagrams or photographs. The former should be drawn and lettered in black ink.]

THE Hungerford Rural District Council has not yet been able to procure a site for its drainage works.

THE Corporation of Derby has gained further respite from the County Council in respect to the drainage scheme.

THE tender of Mr. W. Walkerdine, Derby (£1341 18s. 5d.) has been accepted for carrying out the Chasetown (Staffs.) drainage scheme, prepared by Mr. E. W. Ives, C.E.

A LOCAL Government Board inquiry has been held at Wakefield into an applicaton of the City Council for leave to borrow £14,776 for purposes of street improvement, and £1224 for works of sewerage.

AT the last meeting of the Town Council, Kingston-on-Thames, it was decided to request Messrs. Dibdin and Thudicum to examine and report on the best means of improving the effluent from the sewage works.

A LOCAL Government Board inquiry was held at Dinas Powis on the 27th ult. into an application made by the Llandaff and Dinas Powis Rural District Council for power to borrow £4500 for works of sewerage at Dinas Powis, in the parish of St. Andrew's Major.

A SPECIAL meeting of the Leyton Urban District Council was held recently to discuss a lengthy report of the surveyor on the drainage of the district. The report showed the necessity for the practical reconstruction of the whole drainage system of the district at a total cost of about £50,000. The discussion took place in Committee.

THE Ipswich Town Council has decided, on the recommendation of its Sewerage Committee, to replace the existing heavy wood and iron sluices at the outfall by Stoney's patent sluices, so that the sewage and storm water can be much more rapidly discharged than at present. The estimated cost, including brickwork and masonry, is £350, and provision for this has been made in the estimate of the expenditure of the Sewerage Committee for the current year.

AT a recent meeting of the Chipping Sodbury District Council, a report was presented by the Inspector of Nuisances as to the condition of the Horsfield ditch, and it was resolved that an engineer be employed to examine and report upon the cost of preparing a scheme of drainage.

THE Rivers Committee of the Manchester City Council met on the 28th ult. to decide what sum should be borrowed for treating the city sewage at Davyhulme on the bacterial system. It was agreed to ask the sanction of the Local Government Board to the borrowing of £160,000. This sum, it is estimated, will be required for thirty-seven acres of bacteria beds, and the purchase of the necessary land for aëration purposes.

A LOCAL Government Board inquiry has been held at Dalton recently, into the application of the Urban District Council for sanction to borrow the sum of £11,500 for carrying out a scheme for dealing with the sewage of the district. The scheme was explained by the engineer, Mr. Radford, of Nottingham, and it is proposed to acquire a large portion of land belonging to Mr. W. B. Beaumont, near to Swallow Hill, Mapplewell, for the outfall works. The estimate is exclusive of the cost of the site.

THE seventh annual report of Mr. Bartie, Sanitary Inspector of Selkirkshire, dealing with the year 1897, has just been issued. The report states that more attention is being given to proper drainage of houses, but there is an unwillingness to carry out improvements, especially in old cottage property, the tendency being rather to allow it to go to ruin than to keep it fit for habitation. Drainage improvements have been carried out at Howden, Laidlawstiel, Ettrickhouse, Clovenfords, South Common Cottage, Yarrowfeus, Beechwood, and Bannerfield.

A SPECIAL sitting of the Poole magistrates was held recently at the Guildhall for the purpose of hearing objections to the sewerage of Heckford Park, Longfleet, under the Private Streets Works Act. Mr. John Elford, borough surveyor, produced the plans, estimates, and apportionments for sewering the district, and bore out the statements of the town clerk as to the desirability of carrying the sewage of the houses along the Garland-road through a sewer in the Garland-lane. If the sewage was not taken in that manner it would become necessary to lay iron pipes under the houses and connect with the sewer in Garland-road, which was an objectionable thing to do and would not receive the sanction of the Council. The case for the objectors, as stated by Mr. Trevanion, was that Garland-road was a public road, and therefore the Corporation should not seek to make the property-owners whose property abutted on the high road carry their sewerage into the back-road, and thence have to pay their contribution towards the works under the Private Streets Works Act as well as for the public sewer. The magistrates upheld the apportionments of the Town Council, and the objections were all disallowed.

A LOCAL Government Board inquiry was held at Thrapston recently by Mr. Sandford Fawcett, A.M.I.C.E., in respect of an application made by the Council to borrow money to carry out a drainage and sewage disposal scheme prepared by Messrs. Sharman and Archer, Wellingborough. The system of sewage disposal is that of the "Universal" Company, Derby.

THE city engineer for Bristol recently reported to the Sanitary Committee on a proposal he made for providing for the drainage of houses at Upper Knowle, the overflow from the cesspools of which now at times came across the road. He proposed a sewer, which would be of permanent utility, discharging into a tank to be constructed in a field upon terms agreed with the owner. The tank would cost about £50, and would serve as a temporary measure. The Committee approved of the proposal.

CHICAGO is determined to put a stop to the pollution of her drinking water. Without waiting for the completion of her great drainage canal she proposes to stop the discharge of her sewers into Lake Michigan, which supplies her with drinking water. Two new sewers are to be constructed, emptying into the Illinois and Michigan Canal, and slight changes will be made in some of the existing sewers to adapt them to this plan. A rather curious feature of the work in hand, according to the *Scientific American*, is an alteration in the grade of a section, 104ft. long, of an old sewer, so that its contents will flow westward instead of eastward. The inclination is very slight, and the required modification will, therefore, be trifling. A flooring of concrete will be laid on the bottom of the great 6ft. conduit. It will be nearly 18in. thick at what is now the lowest end, and less than 6in. thick at the other.

Lighting.

ARRANGEMENTS are being made for the installation of the electric light in the Golden Temple at Amritsar.

THE Vestry of St. Pancras has made a profit on the electric light during the past year of £5000, and now proposes to reduce the price to consumers.

THE Bangor City Council has resolved to carry out improvements on the gas plant at an estimated cost of £22,900, and to erect electric lighting works at a cost not exceeding £10,000.

THE Bakewell Gas Bill, which has already passed through the House of Lords, came before the Examiners of the House of Commons recently, for proof of compliance with the further Standing Orders. There was no opposition at this stage, and the necessary formal proofs having been given, the Bill was ordered to be reported for second reading.

THE Edinburgh and Leith Corporation Gas Bill has passed the Committee on Unopposed Bills in the House of Commons, the preamble being proved by Bailie Kinloch Anderson.

THE Sheffield City Council, at a special meeting held recently, unanimously confirmed the propriety of promoting a Bill in Parliament to acquire the undertaking of the Electric Light Company.

A LOCAL Government Board inquiry has been held at Croydon recently into the application of the County Council to borrow various sums, amounting in all to over £11,000, for electric light extensions, &c.

AT a recent meeting of the Ripon City Council a draft Provisional Order from the Local Government Board for gasworks extension was approved, the Board stating that the time for the repayment of the existing debt could not be extended beyond five years.

THERE are signs that the Keighley Corporation is about to approach the question of electric light supply in earnest. A visit was paid last week to Southport, and steps are to be taken to obtain a Provisional Order to enable the Gas Committee to supply the newer illuminant.

IT has been proposed that, in addition to the £95,000 to which the Glasgow Corporation already stands committed, a further expenditure of £61,000 be authorised for Port Dundas station and mains; and that an expenditure of £108,000 be authorised for the South-side station and mains.

HIGH WYCOMBE is now within measurable distance of the completion of its much-debated and long-anticipated electric lighting scheme. The necessary works have been commenced, and the ceremony of the foundation-stone laying, which took place recently, marks a stage in the advancement of the scheme, from which the progress to completion, it is understood, will be so rapid—excepting any eventualities which are at present unforeseen—that on the 1st of July the town will be able to switch on the new illuminant.

THE result of the working of the electric light in Shoreditch for the nine months to the end of March is awaited with much interest, and already rumours are getting about that the financial statement will show a profit of over £2000. Let us hope this will prove to be correct, for a great deal must depend upon the result of the experiment in Shoreditch. Extensions have already been decided upon, and the Authorities concerned are showing great energy and enthusiasm in carrying out the scheme. The eyes of the country—and beyond—are turned towards Shoreditch in regard to the working of the combined scheme, and the example will doubtless be followed in many other places.

THE Waterford City Gas Company Bill, which has passed the House of Lords recently, came before the Committee of the House of Commons on Unopposed Bills. The Bill has been promoted to secure further powers to the City of Waterford Gas Company in connection with their undertaking, including authority to raise additional capital, and to consolidate the existing capital into stock bearing a uniform standard rate of dividend of 5 per cent. The preamble having been proved, the clauses, with a few slight verbal amendments, were passed, and the Bill was ordered to be reported for third reading.

AT a recent meeting of the Edinburgh and Leith Gas Commission it was reported that the consumption of gas in Portobello had increased enormously since the amalgamation with Edinburgh, and to meet it the Commissioners agreed to have a new main laid from the Edinburgh works to Portobello, at an estimated cost of £7000. When it is laid the Portobello works will only be used during times of pressure. The new main would be laid so as to be part of the distributive plant from the new works at Granton. It was resolved to raise the price of gas for the lighting of common stairs in Edinburgh from 15s. 9d. to 18s. 11d. per lamp per year. The additional charge to the Corporation of Edinburgh would be £1224 a year.

FURTHER important developments are contemplated in St. Pancras. At a recent meeting of the Vestry, a report of the Special Dusting and Destructor Committee stated that since the cells at the refuse destructor had been reconstructed the superintendent had reported that there was a great amount of heat for which he had no use. The Committee had been in communication with the Electricity and Public Lighting Committee with regard to the utilisation of this waste heat for heating the boilers for driving the machinery of the adjoining electricity station. The chief electrical engineer had investigated the matter, and was satisfied that the destructor works could supply the electricity station with heat for the machinery. As to the actual amount of heat which could be supplied from the destructor to the station, the engineer had promised to make a test in regard thereto, and to report the result.

PERHAPS the town of Fort William may be said to be the first real instance where the electric light has entirely taken the place of gas to such an extent that the manufacture of the latter has ceased. Fort William had what was understood to be the oldest gasworks in Scotland, and shortly after the opening of the West Highland Railway it was purchased from the owners by Mr. H. Mayberry, Glasgow, who applied for, and obtained, parliamentary powers to become the Lighting Authority of the town and district, and to erect a new gasworks within a limited period. A site had been procured, but in the interval an electric light company was formed, which from water-power close by has succeeded in introducing a first-class light. The railway stations are now lit up with the electric light, and the West Highland Railway Company has now agreed to take over the gasworks' properties, which bound its line of rails in the immediate vicinity of the station.

Obituary.

MR. HORACE CHALDECOTT, OF DORKING.

THE death of Mr. Horace Chaldecott, a well-known local surgeon, took place at his residence early on the morning of the 22nd ult., in his fifty-third year. The deceased gentleman had been suffering for some months past from a painful internal complaint, which left no hope of his recovery. He commenced practice in Dorking in partnership with his brother, Mr. Chas. W. Chaldecott, in the year 1868, but subsequently a mutual dissolution was come to, and each carried on separate practices. Mr. Chaldecott was, until he resigned a few weeks ago, one of the Medical and Vaccination Officers to the Dorking Union, and was also one of the surgeons to the Dorking branches of the Foresters and Oddfellows. In 1871 he married Mrs. Danby. He was the youngest son of the late Mr. William Chaldecott, of Dorking, and uncle to Mr. Howard J. Chaldecott, the Chairman of the Dorking Urban District Council.

DR. PATERSON, OF BRIDGE OF ALLAN

THE death took place on Friday, 22nd ult., at Bridge of Allan, of Dr. Alexander Paterson, the well-known horticulturist and antiquary, after an illness extending over several months. The deceased gentleman was a native of Dundee, and was born in 1822. In his sixteenth year he entered the medical classes in Edinburgh University, and obtained his degree of M.D. in 1843. He began the practice of his profession in Edinburgh, but his health giving way he was recommended to visit Bridge of Allan. He derived so much benefit from the change that he settled down in the village as medical practitioner, and during his long life he never lost an opportunity of bringing the merits of the Bridge as a health resort before the world by correspondence to the Press and otherwise.

He held the office of Medical Officer for the burgh, and was a Justice of the Peace for the county of Stirling. Not only in the district in which he resided, but all over the country, Dr. Paterson's death will be deeply regretted. He leaves a widow and grown-up family.

OUR PRISON SYSTEM.

(*To the Editor of* THE SANITARY RECORD.)

SIR,—In yours of the 22nd you state that "it was ascertained that of 180 prisoners discharged from convict prisons last year no less than 97 had gained in weight on an average of 7 lb." Permit me to remark, first, that this only applies to convict prisons, and not to the ordinary prisons, in which the great majority of prisoners are confined. Convict prisons are, in fact, those set apart for prisoners undergoing a sentence of penal servitude,

in which, owing to its duration, scientific starvation could not be carried to the extent which would be possible in ordinary prisons where the duration of sentences is much shorter; secondly, that in fact the Home Secretary was not referring to convict prisons generally, but to Dartmoor in particular; thirdly, I strongly suspect that the number, which the reporters set down as 180, was really 380, for I find that in the last published return—that for 1896—the prisoners released from Dartmoor during the year, in the ordinary course, exceeded 370. I should be very much surprised if this number fell to 180 (or less than half) in the course of a single year. Men are usually sent to penal servitude at an age when an increase of weight might naturally be expected, and if only 97 out of 380 exhibited such an increase, it would, I think, tend to bear out the charge of scientific starvation rather than to refute it.

Over 1200 persons were liberated from our convict prisons in 1896. You will see the absurdity of supposing that only 180 were liberated in 1897—unless all releases were stopped in honour of the Jubilee. In any case, it was not a year for the liberation of the captives.—Yours faithfully,

INQUIRER.

Dublin, April 29th.

Notes and Queries.

Subscribers have the privilege of obtaining advice in this column on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed to THE EDITOR, "Notes and Queries," THE SANITARY RECORD, 5, Fetter-lane, London, E.C.

NOTE.—If an answer be required immediately, a stamped addressed envelope must be enclosed, when we will endeavour to furnish a copy of the answer by post, as owing to the large number of queries received we cannot guarantee the insertion of a reply in the succeeding issue.

1061.—THE BREAD ACT, 1836: PROVISIONS OF.—"A. B." writes:—"This Urban Council have passed the following resolution:—'That the Sanitary Inspector be empowered to take all the necessary steps to enforce the provisions of the Bread Act, 1836, within this district.' Will you kindly advise me as to the following:—(1) Can bread be legally sold other than in quartern or half-quartern loaves? (2) If bread can be sold in varying weights, can the seller be proceeded against so long as he only charges in proportion to the weight sold? (3) In the purchasing of a loaf or loaves of bread, is it necessary, in view of legal proceedings, to make any statement to the seller at the time of purchase, as is the case when purchasing samples of food for analysis? (4) Can I purchase by deputy? (5) What course ought I to take in instituting proceedings, when the seller has sold bread otherwise than by weight, and the loaf is lighter than the quartern or half-quartern, and yet charged for as full weight?"

Answer.—It is necessary to observe that the resolution directing the "Sanitary Inspector" to take the necessary proceedings is not in order, as there is no such officer under the Public Health Acts—excepting the Public Health (London) Act, 1891, and the Public Health (Scotland) Act, 1897—as a Sanitary Inspector. The title to be used in legal proceedings should be "Inspector of Nuisances," and not Sanitary Inspector, otherwise proceedings may fail. (1) Yes. See Secs. 3 and 4 Bread Act, 1836. (2) No. (3) It does not appear to be necessary. (4) Yes. (5) Lay a complaint before a Justice of the Peace within forty-eight hours after the offence is committed. See Secs. 18, 20, and 31 of the Act. Our correspondent should obtain a copy of the Bread Act, 1836, price 10d. post free, from the Sanitary Publishing Company.

1062.—BOYLE'S EXHAUST VENTILATORS: COST OF.—"J. C." writes:—"Would you be kind enough to inform me what the cost of Boyle's exhaust ventilator would be, and how placed on roof? It is only for a small hall, and I have not seen a ventilator of this kind put in."

Answer.—Boyle's latest improved patent air-pump ventilator, which can be recommended for the purposes required, is made in different sizes from 12in. diameter, with 4in. to 6in. pipe, price £1 12s.; up to 54in. diameter, with 18in. to 27in. pipe, prices £19 15s. to £41 10s. We should recommend our correspondent to communicate with the patentees, Messrs. Robert Boyle and Son, Ltd., 64, Holborn-viaduct, London, furnishing them with particulars as to area and cubic capacity of room, when they will advise him as to the proper size of exhaust ventilator to be used, and price, and also give instructions as to the method of fixing.

1063.—PURIFICATION OF WATER: BOOK ON: RECOMMENDED.—"F. G. H." writes:—"Can you please tell me of a good book on the purification of public water supplies? I have Dibdin's 'Purification of Sewage and Water,' and require an additional work on the subject."

Answer.—Our correspondent will find Rideal's "Water and its Purification," price 6s., an excellent book for his purpose. Another good book is "The Filtration of Public Water Supplies," by Allen Hazen, late chemist in charge of the Lawrence Experiment Station of the Massachusetts State Board of Health. Price 8s. 6d. This book may be obtained from the Sanitary Publishing Company, 5, Fetter-lane, London, E.C., post free on receipt of the published price.

1064.—SANITARY INSTITUTE EXAMINATIONS: AGE LIMITS, &c.—"J. B." writes:—"Will you kindly inform me what are the age limits and subjects of examination for Sanitary Inspectors, also the best books and their prices for the study of the required subjects?"

Answer.—Candidates for the Sanitary Institute Examinations must be more than twenty-one years of age. The subjects of examination may be obtained from Mr. G. White Wallis, secretary of the Institute, Parkes Museum, Margaret-street, London, W. We recommended in our reply to Query 1034, in our issue of April 15th, a list of books to be studied, to which our correspondent should refer.

1065.—INSTITUTE OF SANITARY ENGINEERS: ADDRESS OF.—"T. H. S." writes:—"Will you kindly favour me with the name and address of the secretary to the Institute of Sanitary Engineers?"

Answer.—The offices of the Institute of Sanitary Engineers are at 63 and 64, Chancery-lane, London, W.C., the secretary being Mr. Edward C. Toller, to whom communications respecting the Institute should be addressed.

1066.—SMOKE-TESTING MACHINES FOR DRAINS.—"Inquirer" writes:—"I am asked by the Council of which I have the honour to be Medical Officer of Health to acquire the best smoke-testing machine for drains. I know of several, but would like your opinion as to which are the best kinds. I always, I may say, look forward to the reading of THE SANITARY RECORD with very much pleasure."

Answer.—Probably the best smoke machine obtainable for testing drains is the "Eclipse" patent drain tester, manufactured by Messrs. Burn Brothers, 23 and 24, Charing-cross, London, S.W. Expanding plugs of 4in., 6in., and 9in. diameter should be procured with it.

Another good machine is the "Asphyxiator," manufactured by Messrs. John Watts and Company, Broad Weir Works, Bristol. We are pleased to have our correspondent's appreciation of THE SANITARY RECORD.

1067.—RAILWAY COMPANIES' PREMISES: APPLICATION OF ACTS AND BYE-LAWS THERETO.—"M. D." writes:—"In the urban district of A., a railway company have numerous workshops. (1) Has the Inspector of Nuisances power to inspect the workshops (upon the company's premises) as to the sanitary arrangements? (2) If H.M. Inspector of Factories should visit the above-mentioned workshops, and report to the Sanitary Authority as to the unsanitary conditions, can the Inspector of Nuisances then inspect the premises? (3) Should there be insufficient closet accommodation for the workmen, upon whom must the notice be served? (4) Does Sec. 20, Sub-section 4, of the Public Health Acts Amendment Act, 1890, apply to workshops owned by a railway company?"

Answer.—Our correspondent evidently labours under a misapprehension as to the powers of Sanitary Authorities in relation to buildings belonging to railway companies. Sanitary Authorities have the same jurisdiction as regards nuisances, insufficient water-closet accommodation, drainage, water supply, and the general sanitary condition of buildings owned by railway companies, as they have over any other premises within their district. The only exemption which is provided for in regard to such buildings is that whereby the bye-laws in regard to new streets and buildings are not applicable to buildings belonging to a railway company, and used for the purpose of such railway under an Act of Parliament, as prescribed by the last clause of Sec. 157 of the Public Health Act, 1875. But this exemption, it should be observed, does not extend to cottages for workpeople, but is confined to buildings which are part of stations or warehouses adjoining stations, and so directly connected with the traffic of railways. (1) The Inspector of Nuisances has the same powers of inspection of workshops belonging to a railway company as he has in regard to any other workshop. (2) Certainly. (3) Notice should be served upon the secretary of the railway company. (4) No.

1068.—BYE-LAWS AND REGULATIONS DEFINED.—"H. G. G." writes:—"Would you kindly inform me what is the difference between a bye-law and a regulation under the Public Health Act, 1875? This question was asked at a recent examination of the Sanitary Institute for Inspectors of Nuisances."

Answer.—By-law or bye-law (from the Scandinavian *by*, a town, as Whitby, and *law*) means a local or private law. In public health, a law made by a Local Authority in pursuance of the special powers given by the statutes. Thus, bye-laws may be made under Secs. 44, 80, 90, 113, 141, 157, &c., of the Public Health Act, 1875. Bye-laws when made by a Local Authority under the Public Health Acts do not take effect (and are thus distinguished from regulations) until they have been submitted to and confirmed by the Local Government Board, as provided by Sec. 184 of the Act of 1875. Regulations are rules or orders prescribed by a Local Authority as to the action of those under their control. For instance, regulations may be made with respect to the duties and conduct of servants employed by them, under Sec. 189 of the Act; or they may be described as a governing direction, as, for instance, under Sec. 21 of the same Act,

INSURANCE.

THE MUTUAL LIFE INSURANCE COMPANY OF NEW YORK.

PRESIDENT:
RICHARD A. McCURDY.

Policy-holders in the "Mutual" enjoy the advantages of

SECURITY—
Assets, 1897.. .. exceed £52,000,000
Surplus.. .. .. exceeds 7,250,000

ADAPTABILITY—
LIFE INSURANCE.
INVESTMENT.
INCOME.

PROMPTITUDE—
Claims paid in London immediately on receipt of satisfactory proofs.

LIBERALITY—
Bonuses have, in many cases, trebled the original sum.
Surrender values of unique liberality paid.

Detailed information supplied on application.

Head Office for the United Kingdom—
17 and 18, CORNHILL, LONDON, E.C.
D. C. HALDEMAN, General Manager.

ANTISEPTIC
DISINFECTANT. DEODORANT.
INODOROUS DISINFECTION.
Chinosol

Absolutely Non-Poisonous, Non-Corrosive, Non-Volatile, and does not Stain.
See published Bacteriological Report by Dr. E. KLEIN, St. Bartholomew's Hospital, London.

CHINOSOL SANITARY TABLETS are the most convenient, most effective, and most economic for the immediate production of Disinfecting Fluids. 12 Tablets, packed in one tin to carry in waistcoat pocket, price 2s. One Tablet in warm or cold water produces in less than one minute:—
3 Quarts of a strong Deodorant and Disinfectant, sufficient to spray one infected room of 1000 cubic feet; or
3 Gallons of a strong Disinfectant for flushing drains, walls, floors, &c.

Literature (Dr. Klein's Report) and Samples free to the Profession.

36, ST. MARY-AT-HILL, LONDON.
Telegraphic Address: "CARMINES, LONDON. Telephone: Avenue 5976.

whereby regulations may be made in respect of the mode in which drains may be connected with sewers. See also Secs. 125, 143, &c. Regulations differ from bye-laws, as enacted by Sec. 189, in that, as previously described, they are not required to be submitted to the Local Government Board for confirmation or approval.

1069.—SURVEYING AND LEVELLING: PRACTICAL INSTRUCTION IN.—"W. H. R." writes:—"Will you kindly inform me where I can obtain practical instruction in surveying and levelling?"

Answer.—Classes for instruction in practical surveying are, we believe, conducted at King's College, London. Mr. Richard Parry, F.S.I., &c., 27, Great George-street, Westminster, we notice, also advertises in respect to classes on this subject which are conducted by him.

1070.—NUISANCE FROM OVERFLOWING CESSPOOL: WHO IS RESPONSIBLE FOR?—"Nemo" writes:—"I am the owner of a parcel of land, and at a point therein a drain receiving the drainage of several piggeries, which exist on the land of another owner, terminates in a soak-away. This is now deemed to be a nuisance, and the Urban District Council call upon me to abate it, which, although not caused by me, is on my land. (1) Can the Urban Authority compel me to abate the nuisance, or does the responsibility rest with the adjoining owner? (2) Should I be justified in stopping up the drain at the point C, or in pulling up the pipes which are laid on my land? (3) If I am liable for the abatement of the nuisance, what action would you advise me to take, having in view the fact that I am desirous of building on my part of the land?"

Answer.—(1) This will depend on whether the drain from the piggeries is a sewer, and vested in the Urban Council. It seems to us that it is not a sewer, and that the nuisance must be abated by the owner on whose land it occurs. See Meader *v.* West Cowes Local Board (61 L. J., ch. 561; L. R., 3, ch. 18). (2) No. (3) If the adjacent owners have acquired an easement in respect to the drain in land belonging to our correspondent, he should remedy the nuisance by the construction of a cesspool or additional drain. If, however, it could be shown that the drain is a sewer vested in the Urban Authority, the owner might call upon the Urban Authority to provide proper means of drainage.

Contracts Open.

dates given below are the latest up to which tenders can be received.

BARROW-ON-SOAR (LEICS).—May 9th—Sewers—Mr. Herbert Herrod, surveyor, Barrow-on-Soar.

EMBLETON (NEAR ALNWICK).—May 9th.—Cleaning Sewage Ditch.—Mr. H. W. Walton, clerk, Alnwick.

BELFAST.—May 10th.—Sewers.—The City Surveyor's Office.

SURVEYOR, &C. (LONDON, S.E., May 9th).—For the Vestry of Camberwell. Salary £500 per annum, rising by annual increments of £50 to a maximum of £700. Application forms to be obtained from Mr. C. William Tagg, vestry clerk, Vestry Hall, Camberwell.

SVRVEYOR, &C. (LLANDRINDOD, WELLS).—For the Urban District Council. Salary: Surveyor £20, inspector £20, and collector £25 per annum.—Mr. D. C. Davies, clerk to the Council, Llandrindod Wells, Radnorshire.

COMPETITIONS.

FORMBY (LANCS), July 1st.—Sewerage Scheme.—The Formby Parochial Committee invite competitive schemes for the sewerage of a portion of the township of Formby. Premiums are offered amounting to £100 for the scheme considered first in order of merit, £50 for the second, and £25 for the third. Mr. J. H. Havelock Sutton, Piercefield-road, Formby. A professional assessor will be appointed to adjudicate upon the plans.

To Medical Officers, Surveyors, Sanitary Inspectors, &c.—High-grade Cycles at reasonable prices for prompt cash and on the GRADUAL PAYMENT SYSTEM. Catalogue post free.—MELROSE CYCLE COMPANY, Coventry.

OFFICIAL ADVERTISEMENTS.

BOROUGH OF SCARBOROUGH.

ASSISTANT SANITARY INSPECTOR.

The CORPORATION of SCARBOROUGH REQUIRE a Temporary duly-certified ASSISTANT SANITARY INSPECTOR.

Salary 30s. per week.

Applications in applicants' own handwriting, stating age, qualifications, and previous experience, and enclosing copies of not more than three testimonials, and marked outside "Assistant Sanitary Inspector," to be sent in to me not later than Twelve o'clock (noon) on Tuesday, the 17th inst.

JOHN E. T. GRAHAM,
Town Clerk's Office, Scarborough, Town Clerk.
May 2nd, 1898.

BATH URBAN SANITARY AUTHORITY.

The above Authority are about to APPOINT a duly qualified ASSISTANT SANITARY INSPECTOR.

Candidates must state age, qualifications, previous experience, and salary required.

The duties will be to assist the Medical Officer of Health and Inspector of Nuisances in the performance of their duties under the Sanitary Acts, and the officer will be required to devote his whole time to the duties of his office.

Applications, in his own handwriting, endorsed "Application for Assistant Inspectorship," accompanied by not more than three testimonials of recent date, to be delivered to the undersigned on or before Saturday, the 14th day of May, 1898.

Dated, 5th May, 1898.

By order,
F. H. MOGER,
3, Wood-street, Bath. Clerk.

SANITARY INSPECTOR.

THE VESTRY of the PARISH of LAMBETH REQUIRE an additional SANITARY INSPECTOR.

Candidates must possess the Certificate of the Sanitary Institute, and should have a knowledge of plumbing, drain-laying, and building construction.

The Inspector to be appointed will be subject to the Vestry's superannuation scheme; must reside within the parish, and, if required, in the particular district (part of the Inner Wards) which will be allotted to him; must devote his whole time and attention to his duties, and not engage in any other occupation; and must be prepared before entering upon his duties to undergo a medical examination similar to that required by the recognised Friendly Societies of a candidate for membership. He will be subject to the orders and regulations of the Local Government Board and to the existing and future bye-laws and orders of the Vestry.

Age to be not less than 30, nor more than 45.

Salary £120, rising £5 yearly to £170. No claim to a pension. Uniform will be provided.

Applications to be made in the candidate's own handwriting on forms to be obtained at the Vestry Hall, and sent to the undersigned, with copies of not more than three recent testimonials, on or before the 2nd day of June next. Original testimonials, if sent, will not be returned.

Canvassing, either personally or by letter or through friends, will disqualify.

The election will take place at the Vestry Meeting to be held on Thursday, the 7th day of July, at Seven o'clock p.m.; but selected candidates will receive notice of the day they will be required to attend at the Vestry Hall.

HENRY J. SMITH,
Clerk to the Vestry.
Lambeth Vestry Hall, Kennington-green, S.E.,
May, 1898.

SANITARY INSTITUTE EXAMINATIONS.

TUITION BY CORRESPONDENCE.

An Engineer and Surveyor (Mem. San. Inst.), Certificated Surveyor and Inspector, prepares students for these Exams. by Correspondence through the post.

Fees strictly moderate. Cramming studiously avoided.

The course of tuition is arranged so as not only to qualify the student for passing the exams., but what is of equal importance, viz., that he may become a thoroughly efficient Inspector.

On successfully passing the exams., all possible assistance and advice is given to help forward intending candidates for public offices.

Many of my old pupils are now filling positions with salaries of over £120 a year.

For terms, &c., address "C. E.," care SANITARY RECORD, 5. Fetter-lane, London, E.C.

SANITARY INSTITUTE EXAMINATIONS.

SPECIAL Corresponding Classes for the **Practical Sanitary Science,** and **Sanitary Inspectors' Examinations** of the **Sanitary Institute, 1898,** conducted by a gentleman holding appointments as Urban District Council Engineer and Sanitary Inspector, holder of three certificates from the Sanitary Institute, First-class Honour Medallist Hygiene, &c. Hundreds of successes.—For all particulars, testimonials, &c., apply Mem. San. Inst., Office of THE SANITARY RECORD, 5, Fetter-lane, London E.C.

Striking testimony to the value of THE SANITARY RECORD as an Advertising Medium.—The following, recently to hand from Messrs. Bugler and Co., of Alpha Works, Putney, makers of the well-known Inspection Eye Cover for drains, is to the point:—"We are pleased to tell you that since putting these covers, &c., on the market, our hopes have been more than realised, thanks, doubtless, in a great measure to THE SANITARY RECORD."

Notes.

Adulterating Dairy Products.

SELDOM has a more influential deputation appeared before the head of a governmental department than that which waited upon Mr. Chaplin last week, with the object of urging her Majesty's ministers to fulfil the promise of last year and introduce a Bill dealing with food adulteration. Over seventy of the leading agricultural and kindred societies of the kingdom were represented, and each country had a spokesman. The primary object of the deputation was to point out that if British dairy produce was to be protected, as well as the public being secured against fraud, any measure should include four special points:—"The establishment of a Court of Reference for fixing standards of purity; the examination of dairy products at the ports, with the view of checking the importation of adulterated produce; the prohibition of the artificial colouring of the margarine to resemble or imitate butter; and the prohibition of the sale of mixtures of margarine and butter." Further, it was contended as to the growing importation of foreign milk, that in the interests of the public health that product ought not to be allowed to be sold in this country when it was produced under unsanitary conditions. The introduction of preservatives or antiseptics was condemned.

No Hope for Legislation this Year.

THE speakers did their utmost to make out a case, and prove the urgency for action on the part of the Government; but very little encouragement was given in the reply made by Mr. Chaplin. And it is always so with Governments. Measures are placed in the front of the sessional programme about which the community have little or any concern, whole evenings may be wasted in the excited discussion in the affairs of other nations and peoples, but pressing reforms at home are relegated to a "back seat," only to be quietly snuffed out when the "slaughter of the innocents" commences. Granted that some of the points raised may be of a debateable character, it is well known that most flagrant adulterations are practised by some, and fresh powers are needed to put an end to such practices. And the law should be made equally applicable to foreigners as to the home producer; for here is the hardship justly complained of by members of the deputation—their dairies, &c., are subject to the most minute and critical inspection, and properly so, yet there is no guarantee that the produce from other countries does not come from places where unsanitary conditions prevail, or that the animals on the farms are not suffering from disease.

The Cost of Cremation.

IN recent years there has been considerable change in public opinion, or rather sentiment, with regard to the disposal of the dead. Gradually the crowded state of cemeteries and the possible danger to the neighbourhoods surrounding them, is compelling the belief that a more rational method of burial might be adopted. The "earth to earth" coffins are being largely adopted; but many contend that these do not fully satisfy sanitary requirements, and that eventually cremation will have to be universally adopted. There appears to be considerable difference of opinion as to the cost of this method, but from a statement issued by the Cremation Society of England, it would appear that it does not greatly exceed the cost of an ordinary interment. We are informed that the actual charge for cremating a body at Woking is £5, but there are many other expenses, such as getting to and from the crematorium, which is 2¼ miles from Woking station, and it is estimated that the "cost of cremating a body of a person dying in London need not exceed 15 guineas, including all charges." The cost of the land and building at Woking was £5872, and one year's expenses amounted to £699 15s. for 173 cremations, but the actual net cost of the cremation itself worked out at a little less than £2 a body, the rest being swallowed up in

other necessary expenses. The large initial outlay prevents Local Authorities from adding crematoriums to their cemeteries.

"Not a Happy Lot."

Some will remember the celebrated Gilbertian chorus which tells that a "Policeman's lot is not a happy one," and their thoughts will inevitably go back to those lines as they read in our "Law Reports" the adventures of a Lady Sanitary Inspector at Liverpool. Miss Burton, an officer of the Corporation, in the course of her visits, called at the house of a dock labourer. The wife of this individual appears to associate all public officials with the School Board officer, and seeing Miss Burton in uniform, had a vague idea that she was after the "young 'uns," and immediately gave utterance to some very uncomplimentary remarks. But the Inspector was not to be denied, therefore she was taken into another room, where the said dock labourer "reclined upon the sofa." From this position he jumped up, seized Miss Burton "by the arm, and his wife blocking the doorway, the unfortunate Inspector was detained in durance vile for a good half-hour, the defendant insisting on examining her book, to see what names she had down. She was liberated ultimately, upon the intercession of one of the children. The defendant pleaded in extenuation, that he had just had some words with his wife, and it was suggested that he was consequently in a condition of irritation against womankind in general." For his "condition of irritation" he was deservedly fined 20s. and costs. Moral for Lady Inspectors: Before visiting any house, find out if the "husband has had words with the wife," or else it may go hard with you.

Sewers for Trade Refuse.

A judgment of more than ordinary importance to Local Authorities throughout the country has just been given by the House of Lords. The owners of a paper mill applied for a mandamus to compel the Local Authority to provide sewage accommodation, into which they could run the liquid from their works. This claim was made under the Public Health Act. The District Council denied that the plaintiffs could proceed under the Act, and maintained that if they had any remedy at all, it must be by appealing to the Local Government Board, who, if it thought a good case had been made out, could compel the Local Authority to carry out the work they had neglected. A mandamus was granted by the Court of First Instance, but this decision was reversed on appeal. The Lord Chancellor, with whom other members of the House concurred, took the view of the Court of Appeal, Lord Halsbury remarking that it would be unreasonable to permit a man to go into a small district and require the Local Authority to reconstruct its sewerage system for his benefit.

The Sewage Commission.

Mr. Chaplin has now announced the names of the members of the Royal Commission on Sewage Disposal. They are—the Earl of Iddesleigh (chairman), Sir Richard Thorne Thorne, Professor Michael Foster, Professor William Ramsay, Major-General Carey, Dr. J. B. Russell, Colonel Harding, Mr. T. W. Killick, and Mr. C. P. Cotton. The terms of the reference are, "to inquire and report what method of treating and disposing of sewage, including any liquid from any factory or manufacturing process, may properly be adopted for the protection of public health, and for the economical and efficient discharge of the duties of Local Authorities; and if more than one method might be so adopted, by what rules, in relation to the nature or volume of sewage, or population to be served, or other varying circumstances or requirements, should the particular method of treatment and disposal to be adopted be determined; and, secondly, to make any recommendations that may be deemed desirable with reference to the treatment and disposal of sewage."

The Scope of the Inquiry.

It will be seen from the scope of the remit that the field of inquiry will probably be a very wide one, and looking to the composition of the Commission, too, we may have every confidence that the inquiry will be searching and exhaustive. The relative merits of the various competing systems that at present divide the field will be carefully weighed and compared, and the efficiency of each system, and its suitability to the circumstances of any particular locality, will as far as possible be determined. It is too much to expect, perhaps, that the inquiry will result in the exclusive recommendation of the biological or bacterial filter system, which has grown so much in favour with scientists in recent years, or, indeed, of any other system; but, at all events, a flood of light will be thrown on the circumstances and conditions to which each method is applicable. Reliable information will also be obtained as to the relative costs of the different methods, which will be of immense service to perplexed Local Authorities, who are at present under the necessity of instituting elaborate inquiries themselves before embarking on the task of sewage purification.

Another case of Nominal Fines.

In a recent issue we drew attention to a case of the lax enforcement of the Food and Drugs Acts in Sunderland, and a few days later we observed that the Home Secretary was questioned in the House of Commons about a case that occurred in Southampton, where an offence against the Factory Acts was treated by the magisterial bench in a similar carelessly light-hearted spirit. A conviction was obtained against a firm of drapers for having kept three of their girls at work for 22½ hours continuously, and from midnight to seven in the morning, without even an interval for a meal; and what made matters worse was that the same firm had been convicted of a similar offence last year. It would be hard to conceive a more flagrant case, and the excuse offered, that it was to execute an urgent order, and that the girls were asked if they would work without an interval—as if in such a case it were a free option—was the thinnest possible palliative. And yet the fine imposed was only 1s. with costs. The Home Secretary marked his sense of the magistrates' treatment of the case by writing a strong expression of his opinion that they were not justified in treating such a violation of the

Acts as a merely technical offence. When cases of this kind occur, we are reminded of the necessity of a strong central department, to see that the intentions of the Legislature are not defeated by the vagaries of easy-going magistrates.

Local Authorities and Parliament.

The inclination to brush aside the behests of Imperial Law is one that especially besets the lesser judicatories, and it probably reaches its most acute phase in regard to the Vaccination Acts. When a man has been raised to the dizzy eminence of the magisterial bench, and feels that he owes his elevation to the divine institution of popular suffrage, he is apt to forget that there is a power higher than that of local ratepayers, and that is the power of Parliament, which rests upon the will of the nation. This attitude was well brought out in the debate on the Vaccination Bill. When Mr. Steadman, the Labour member for Stepney, avowed that the Board of Guardians to which he belonged had absolutely refused to carry out the present Acts, Mr. Chaplin quietly mentioned that under the Bill the institution of prosecutions would devolve in future upon the Vaccination Officers, and not, as hitherto, upon Boards of Guardians. Such an apparent slight of the popular bodies aroused the wrath of the Labour Party, who thereupon forwarded to the President of the Local Government Board a resolution condemning the proposal to enable an official to override the wishes of the electors and the Public Authority. Mr. Chaplin's reply was pithy and unanswerable. "Your contention," he wrote back, "appears to be that local bodies should be able to override the decisions and authority of Parliament. But in my judgment it is the authority of Parliament, and not that of the Local Authority, which should be supreme on a matter affecting the general interest."

The Plague in India.

The centre of interest with regard to the plague in India has now been transferred from Bombay to Calcutta. The experience that Bombay has passed through has been so terrible that it is small wonder that the first report of the outbreak of the plague in the Indian capital should have caused a certain degree of panic among the population. The natives fled at once from the city in large numbers—one estimate puts the number at 250,000—not so much, it is said, for fear of the plague as on account of the dreaded quarantine and segregation rules. But the panic subsided, and the exodus abated, on the Lieutenant-Governor causing it to be made known that the plague rules to be enforced would not be so stringent as those in Bombay; and on his giving an assurance that there would be no wholesale imposition of quarantine, though all suspected or real cases would be strictly segregated, under certain conditions. In fact, as appears from a statement made by the Secretary for India in the House of Commons, the policy of the Government in future is to unite an unflinching enforcement of all really necessary sanitary precautions and regulations with the utmost consideration for the religious susceptibilities of the people. They have had sufficient troubles from this source in Bombay to desire a repetition of them in Calcutta.

Inducements to Inoculation.

The Government policy is revealed in the Lieutenant-Governor's proclamation as to quarantine, and also in the inducements he is offering to the people to adopt Professor Haffkine's system of inoculation against the plague. In order to make the system popular, he has declared that, even should the plague break out in any family, every member of which has been inoculated, the person attacked will not be removed to hospital. Coupled with this declaration is the assurance that in no case will a husband and wife be separated, and every respect will be paid to the purdah system. The popular excitement being thus allayed, one prime source of anxiety for the Authorities is removed; the people are more tractable, and the latest news is that business is resuming its normal conditions. It is reassuring, too, to hear that the very natural fears that were at first entertained have not, so far, been realised. Comparatively few cases have yet occurred, and during the two or three days preceding the despatch of the latest information no cases were recorded. The opinion is now expressed that the outbreak is not epidemic, and we sincerely trust this may prove to be so; though, we fear, it is too early to place much confidence in this optimistic belief.

The Prisons Bill.

The Bill introduced by the Government for the reform of prison administration in England has been referred to the Grand Committee on Law of the House of Commons, which commenced its deliberations on Friday last. The two chief points of interest arising out of the first day's proceedings were, first, a proposal by Mr. Michael Davitt that the Prison Commissioners should include in their number a medical man skilled in mental diseases, a proposal which was adopted by the Committee by 25 to 8 votes, although opposed by the Government—why, we are at a loss to know; and, secondly, the question of corporal punishment, which led to a protracted discussion that had not been concluded when the Committee rose. The amendment under consideration was one providing that the prison rules should not give any power to order corporal punishment; and it was pointed out in support of this position that in Scotland and Ireland there is no provision for the ordering of corporal punishment in local prisons, and that in the Scotch and Irish convict establishments very little corporal punishment is ordered. The Home Secretary, in reply, admitted the desirability of doing away with this form of punishment as far as possible, and his anxiety to reduce it to a minimum; but he did not think it safe to abolish altogether the power to order it in cases of mutiny or gross personal violence. Probably it is wisest to retain the power, subject to certain clearly-defined restrictions and limitations.

TO OUR READERS.

The Editor solicits the co-operation of readers in making THE SANITARY RECORD *more attractive by means of pen-and-ink sketches, photographs, and diagrams. There are many phases of sanitary work which lend themselves admirably to illustration. By this means not only individual articles, but the journal as a whole will be brightened.*

LIME, MORTAR, AND CEMENT: THEIR COMPOSITION AND ANALYSES.

By W. J. DIBDIN, F.I.C., F.C.S., &c.

CHAPTER II. (*continued*).

SUBSTITUTES FOR SAND.

Puzzolano is a volcanic substance of a pulverulent character, of a violet colour, which was first employed in fabrication of mortars by the Romans. It was then, according to Vitruvius, found in the vicinity of Puzzoli, near Baia, and not far from Vesuvius. Subsequently, a similar material has been found in Vivarais, the theatre of extinct volcanic action in the centre of France; near Edinburgh; at a village called Brohl, near Andernach on the Rhine, where it is worked under the name of "trass" or "terrass;" and in almost all localities marked either by the present or past action of subterranean fires. Its aspect, however, varies much; sometimes it is in a state of powder, at others in coarse grains, often in the form of pumice, scoria, or of tuffa, or small rubble stones. Its colour is often brown, or yellow, or grey, or black, even in the same locality.

Tripoli, and the sandstones and limestones, altered by contact with the rocks of eruption, also frequently take the character of puzzolanos, and may be classed, therefore, as pseudo-volcanic products of a similar category. But the conditions under which they were exposed to the heat of the volcanic rocks, and under which they gradually cooled, have necessarily modified their chemical and mechanical nature.

The puzzolanos are principally composed of silica and alumina, with a little lime in combination, mixed with potash, soda, magnesia, and oxide of iron. The following analysis by Bertheir of the puzzolano of Civita Vecchia, and of the trass of Andernach, will be of interest:—

	Puzzolano.	Trass.
Silica	44·5	57·0
Alumina	15·0	12·0
Lime	8·8	2·6
Magnesia	4·7	1·0
Oxide of iron	12·0	5·0
Potash	1·4	7·0
Soda	4·0	1·0
Water	9·2	9·6
	99·6	95·2

A mixture of puzzolano and trass with the blue lias lime, was used by Smeaton in the Eddystone Lighthouse.

Burnt clay is sometimes used as a substitute for sand in mortar, but care should be taken that the clay is thoroughly well burnt, otherwise it will act as so much earthy matter and seriously reduce the hardening qualities of the resulting mortar. Crushed bricks are frequently used, but these simply come under the category of burnt clay.

Scoriæ from ironworks, clinker from brick kilns, and cinders from coal, make good substitutes for sand when they are quite clean and properly used. Unfortunately, in view of the fact that cinders may make a fair mortar under proper conditions, dust-bin refuse is often employed by unscrupulous builders, the whole of the foul refuse therein being included, with the result that there is no binding power, and but too often it creates a nuisance by the decomposition of the contained organic matter.

The main point which will come up for consideration in the subsequent chapter is the relation of weight to volume of these different substances. According to the bye-laws in force in London, the proportion of lime to sand or grit is to be determined by volume, and it will be seen that in view of the many different substances which may with propriety under proper conditions be employed, this question of relative weight and volume is of the first commercial importance.

The following table of the weight of various sands and other substances per cubic foot will therefore be of assistance to the reader. It must not be taken, however, that this table is to be relied upon in those cases where samples of the materials under consideration are obtainable, as in all such cases it should be weighed under normal working conditions. For comparison I have also given, in the table following this, another in which the weight of various limes is stated, but in this case also it will be best, wherever possible, to make direct determinations in each case. The weighings under the head of "Sand, &c.," have been specially made for the purpose of this chapter by Mr. C. Chambers Smith, C.E., to whom I have to tender my thanks for the reliable information thus kindly placed by him at the disposal of my readers.

Weight of One Cubic Foot of Sand, &c.

	lb.		lb.
Pit sand	100	Burnt clay	71
River sand	118	Cinders, clean	60
Broken brick	53		

Weight of One Cubic Foot of Fresh Lime.

In small lumps.	lb.	Ground.	lb.
White chalk	39	White chalk	38
Grey chalk, Halling	44	Grey chalk	43
Portland stone	47	Arden	68
Blue lias	58 to 70	Blue lias	49 to 68

Cements.

	lb.		lb.
Portland	74 to 101	Parian	60
Roman	60 to 62½	Plaster of Paris	50
Medina	61	Whiting	64
Keene's	64		

(*To be continued.*)

NOTES ON PRACTICAL SANITARY SCIENCE.

By WILLIAM H. MAXWELL.

Assistant Engineer and Surveyor, Leyton Urban District Council Author of "Drainage Work and Sanitary Fittings," "Ventilation Heating, and Lighting," &c., Certificates of the Association of Municipal and County Engineers, and Sanitary Institute.

(*Continued from page* 477.)

GENERAL OBSERVATIONS ON REFUSE DESTRUCTORS.

Cost of Construction.—In regard to the initial cost of the erection of Refuse Destructors very little reliable data can be given, as the circumstances of no two cases are, as a rule, even approximately similar. The outlay will necessarily be dependent, amongst other things, upon the difficulty or otherwise of the preparation of the site, upon the nature of the foundations required,

the height of the chimney shaft, the length of the inclined or approach roadway, and also upon the varying prices of labour and materials in different localities.

Information derived from "returns" of the costs of erection at various towns is of but little practical value, and, for all purposes, must be accepted with the greatest caution, as it is impossible to make useful comparisons between the costs of erection at various places without knowing the circumstances of each. Incidental works, such as boundary fences, special foundations due to bad ground, extra tall chimney shaft, mortar mills, engines, &c., may be included in the one case and not in another.

These differences will be apparent from an inspection of the following table, which gives the approximate initial outlays for the destructors at the places mentioned :—

Town.	No. of cells.	Height of shaft in feet.	Initial outlay, exclusive of site.	Cost p. ton of burning refuse, exclusive of interest on cost of works.
			£	s. d.
Battersea	12	180	12,000	2 10
Bootle	12	170	9,200	0 10½
Bournemouth... ...	6	140	3,171	0 9
Bradford	12	180	10,250	0 6
Brighton	12	225	16,679	1 7
Burton-on-Trent ...	8	144	4,266	1 7¼
Buxton	4	150	1,315	0 8
Cheltenham	8	160	6,000	0 7½
Govan	8	120	6,346	1 6½
Hastings	4	130	4,000	1 6¾
Hull	6	180	3,200	0 11
Leicester	6	160	6,694	0 8
Leicester	6	180	8,069	0 8
Leicester	6	180	8,852	0 8
Leyton	8	150	6,000	1 3*
London (City)... ...	10	150	13,311	1 8½
Liverpool (Charters-street)	24	170	11,488	0 9
Oldham	10	120	4,527	0 9¾
Rotherham	6	130	4,000	1 2½
Sheffield	6	180	9,500	—
Sowerby Bridge ...	2	140	1,829	1 2
Stafford	4	135	2,315	0 9
Whitechapel	16	180	10,500	1 1
Withington	6	150	6,600	0 8

* Pressed sewage sludge is mixed with refuse and burnt.

From the above figures it will be seen that the average cost of construction, including the usual accessories, but exclusive of site, at the towns named is about £840 per cell, and the average height of shaft is 158ft.

At Bristol the total cost of a 16-cell destructor was £11,418, of which £2909 was expended in foundations, and £1689 for the chimney shaft, thus leaving £6820 for cost of destructor, buildings, and approach road, or about £426 per cell.

The following averages of returns from thirty-five towns obtained by Mr. Price (whilst surveyor of Toxteth Park) are given by Mr. Boulnois,[149] and will be of interest :—

Average cost of construction of destructors = £525 per cell.

Cost of chimney to erect = £6 3s. 4d. per foot of height.

Height of chimney = 163ft.

Number of tons consumed per diem per cell = 6 tons.

Number of men employed per cell = 1·17.

Cost of destruction of refuse = 11½d. per ton.

Annual cost per cell = £96.

Cost per ton of burning refuse.—The cost per ton of cremating refuse in destructors will depend chiefly upon :—

(1) The type of furnace adopted.

(2) The price of labour in the locality, and the number of "shifts" per day.

(3) The nature of the material to be consumed.

(4) Interest on and repayment of capital outlay.

In many towns the gross cost can often be materially reduced by the sale of clinker, fine ash, mortar, &c.; also by the profitable application of the heat generated for raising steam for any work for which it may be required, such as driving sewage works machinery, pumping, or for electric lighting.

As a result of returns from forty-six towns, collected and published in 1894 by Mr. C. Jones, M. Inst. C.E., it was found that the expense (exclusive of interest and sinking fund on cost of works) incurred in destroying refuse is represented as varying from 3½d. to 1s. 7d. per ton; and about 10d. per ton is considered a fair average.

The average cost of burning refuse at the towns named in the above table, which is compiled from information kindly supplied to me by the Borough Engineers and Surveyors at the places mentioned, is 1s. 1½d.

Mr. Jones also says that the cost of *cremating fumes, &c.*, per ton of refuse destroyed varies from ¼d. per ton where only cinders are used to 3¼d. per ton at Ealing. At Batley, where coke at 10s. 2d. per ton is used, the cost is as high as 7d.

In an interesting report on refuse destructors prepared in June, 1896, by the Borough Surveyor of Ashton-under-Lyne is Table on page 502, showing the relative cost—per ton burnt—in stoker's wages, when *all towns are put upon the same ratio with regard to rate of wages, number of hours per day, and days worked per week.* The basis adopted is an eight-hours shift, 5½ days per week, and a rate of pay of 30s. per week per man.

The value of Town Refuse for Power Production.—The generation of steam by the utilisation of the waste heat of a destructor, although an important asset in connection with such work, should not be pursued as a matter of first importance so as to in any way impair the efficient performance by the furnace of its primary functions as a *refuse destructor.* The proper course, doubtless, is to make the destructor as perfect as possible *as such*, afterwards passing the gases (subsequent to their having fully performed their work in the furnace) through a suitable boiler, and taking the result for what it may then prove to be worth, which in high-temperature destructors is found to be sufficient to effect a considerable saving when steam power is required for pumping, lighting, or any other work.

The primary considerations requisite for a perfect destructor include the following :—[150]

(1) The temperature attained should be sufficiently high.

[149] "Municipal Engineers' Handbook.

[150] Report on "Dust Destructors," London County Council, May, 1893.

TABLE.

Name of city or borough.	Type of destructor.	No. of men to be employed.	No. of shifts per day.	Rate of wages per week.	No. of cells.	Tons per day per cell.	Days per week worked.	Cost in wages per week.	Tons of refuse per week.	Cost per ton destroyed.

Dewsbury	Beaman and Deas'	6	3	30	2	15	5¼	9 0	158	13¾

* Fitted with forced draught.

(2) The duration of exposure to a high temperature should be sufficiently long.

(3) *All* the vapour escaping from the refuse should be heated to a sufficient extent, and there should be no possibility of the escape of any undecomposed vapours into the chimney shaft.

The first requirement implies the use of a forced draught, and the second indicates the impossibility of placing boilers over the hottest part of the furnace, so as to enable them to best utilise the full calorific value of the burning refuse, as the temperature of the furnace would be materially reduced by placing a large mass of comparatively cold water directly over the fire. It should therefore be borne in mind when comparing the evaporative value of towns' refuse with that of coal as used in connection with boilers, that the former cannot be utilised under similar conditions to the latter without impairing the value of the destructor.

In regard to the theoretical calorific value of refuse burnt under the most advantageous conditions for purposes of steam production, Professor Forbes, in his Cantor Lectures before the Society of Arts, 1892, said, "Now it will strike you, as it has struck me, as a very wise provision of Nature, when I tell you that *if* that refuse (at Paddington) were *properly burned*, and *if* it were *used in the most economical way*, it would be found that (assuming the proportion of lighting required for such a population to be, as has been very generally assumed, one lamp per head[151]) the amount of refuse provided by any population is almost exactly as much as is required to supply the illumination by means of the electric light to that same population."

In actual destructor practice, however, refuse is not burned under the favourable conditions assumed above, and the practically attained results do not reach anything like the theoretical estimate.

Mr. J. Tomlinson, B.E., A.M.I.C.E., has deduced, from results experienced at various destructor installations throughout the country, the following statement of the power available for external work, put in each case in the form of I.H.P. continuously per cell, consuming six tons per day of twenty-four hours:—

Batley	8½	I.H.P.
Birmingham	50	,,
Blackburn	5½	,,
Bury	3	,,
Ealing	4	,,
Hastings	5	,,
Hastings (with cremator)	10	,,
Liverpool	4	,,
Southampton	4	,,
Warrington	8½	,,

The high result obtained at Birmingham, where from several tests it appeared that 1 lb. of refuse evaporated 1·79 lb. of water, is explained by the fact that "it was necessary there to keep up steam for the treatment of the excretæ, and steam was got up from these furnaces *by putting the boilers directly over the furnace*. In consequence of this, the combustion is extremely imperfect. The large cooling surface of the boilers impedes the combustion in an effectual degree. In most cases where boilers have been used to generate some steam, the boilers have been put away, and after the gases have passed through the flue they then pass by the boiler, and the error has been in the opposite direction."

In a report on the proposed electric lighting for the borough of Ipswich in regard to the question of a combined destructor and electric light station, Professor Kennedy observes that "it is very easy to overestimate the saving in fuel which can be effected by combining an electric light station with a destructor, yet there is no doubt that some economy will result from the combination, and this is a point which is worth while keeping in mind." Upon the same point the borough engineer, in his report[152] on town refuse destructors, expresses the opinion that whatever the available power for electric lighting may be, it could not be constant owing to necessary stoppages for repairs and other purposes; therefore, an electric light installation, if designed in connection with a destructor, should be complete in itself, but at the same time so arranged that it could take advantage of the heat when available.

Mr. Druitt Halpin has recently introduced a patent process of storing surplus heat, the object of the invention being, instead of generating electricity

[151] One 8-candle power lamp per head for two hours for every night of the year.

[152] March 16th, 1896.

and adopting expensive storage, to store the power which produces the current; the basis of the system being the storage of heated water under pressure in "reservoirs from which steam is taken, through a pressure-reducing valve, when and how required." Halpin's system has been installed at the Shoreditch Destructor and Electric Light Works, and is said to be especially applicable where heat is used from a refuse destructor.

The surplus heat of destructors has been applied not only to purposes of electric lighting, but also to driving mixing machinery at sewage disposal works, air compressing for sewage sludge plant, driving mortar mills, lifts, chaff cutting, pumping water, &c. At Eastbourne the boiler power required for operating the air-compressing engines, in connection with the "Shone" system of drainage, is supplemented by this means.

The relative value of town refuse and furnace coal, as steam producers, has been variously stated. Practical results, of course, depend upon the quality of the refuse and the conditions under which it is burned. Average refuse is frequently stated at about one-tenth the value of good furnace coal; but at Birmingham, where multitubular boilers are set in such a manner as to form the top of the furnace, it is found in practice that 1 lb. of refuse will evaporate 1·79 lb. of water; that is to say, that as a steam producer the refuse is about one-fifth the value of an equal weight of coal.[153]

THE CHEMICAL AND BIOLOGICAL ANALYSIS OF WATER.

By T. H. Pearmain and C. G. Moor, M.A. (Cantab).

Members of the Society of Public Analysts. Authors of "Applied Bacteriology;" "The Analysis of Food and Drugs," &c.

It is now universally acknowledged by sanitarians that a proper supply of unpolluted drinking water is one of the most essential conditions to ensure the health of the community. This being so, it is one of the first duties of the Sanitary Authorities to see that this is provided to every house under their jurisdiction. Most of our large towns are provided with a more or less satisfactory public water supply, but the larger proportion of the population who are resident in villages and isolated dwellings all over the country are dependent upon water supplies derived generally from shallow wells, which in many cases are grossly polluted. This state of affairs is all the more serious in view of our certain knowledge of the conveyance of disease by means of polluted water supplies. One is frequently met with the retort from ignorant persons that such waters have been drunk without harm from time immemorial. Although water contaminated with sewage has been, and is still, drunk by a large number of people apparently with impunity, yet such dangerous waters may at any moment become positively injurious to the health of the persons using them. It is now well known that polluted water is the most important agent in the conveyance of typhoid fever. The slightest contamination of a water supply with the dejecta from a single case of enteric fever has in many well-authenticated instances caused widespread epidemics of the disease amongst those persons who have used the contaminated water supply, as witness the recent epidemics at Worthing and Maidstone.

The object of water analysis is, as a rule, to ascertain the suitability of a water from a particular source for drinking and other purposes. In judging of the suitability of a particular supply it is advisable to ascertain its history as far as possible —that is, the character of the geological strata from which it is derived, the relative positions of possible sources of pollution, such as cesspools, churchyards, stables, &c. This information is frequently withheld by persons submitting a sample for analysis for fear of biassing the analyst's opinion, and thus information that might have been of use is often wanting.

In the absence of the history of a water we have generally to rely on the information we are able to gain from the three methods of examination, which we place in the order of the importance we attribute to them:—

(1) Chemical analysis.
(2) Biological examination.
(3) Physical examination.

The first point to be clearly grasped is that neither any one, nor the whole of these methods, applied to a single sample, or to a few sporadic samples of water, can warrant the fitness of a water supply for drinking purposes. The analysis of such sample or samples may disclose sufficient quantities of substances or bodies of suspicious origin to show that the water is unfit for consumption, or, at least, that it is either derived from sources liable to convey infective material or contains poisonous substances. It may, however, give no such positive results, and this circumstance may be due either to the fact that the water is either pure in itself and not open to pollution, or to the fact that at the time at which the sample was taken no pollution happened to be drawn or forced into the supply. The latter interpretation is very frequently the correct one; and the danger which attends it, if it be not recognised by the Sanitary Authorities, is that due to false confidence, and has been responsible for some of the most serious water-borne epidemics. The means of protection which are available through analysis are due to two facts. When infective organisms are introduced to a water initially proper for consumption, these organisms do not come alone, but are usually accompanied by chemical substances and by other organisms which alter the chemical and biological composition of the water in a manner to be detected by analysis. When no substances which are infective or liable to convey infection are introduced into a water supply, its composition is usually found to be practically constant. It is possible, by taking observations over a sufficient period, to determine whether the composition of a water supply is constant or variable; and before it can be warranted as safe, it must by such systematic and continued examination have been shown to be of practically constant composition in all its factors.

Each of these methods of examination of water has its own special importance, but it may be as well to indicate the information which is gained by these methods of examination. Undoubtedly the chemical examination is the most important, indicating the presence as it does of the smallest

[153] Report on "Dust Destructors." (L.C.C., May 10th, 1898.)

trace of organic matter, and thus indirectly pointing to possible dangers to health.

It allows more accurate and delicate quantitative determinations than are possible by the other methods; and it permits a far larger number of independent factors to be accurately estimated, so that the chance of detecting variation in composition, which is the most important sign of danger in waters which may sometimes or usually be safe, is considerably greater than by other methods. Its least merit is the certainty by which directly poisonous, as distinguished from infectious, material is detected; for such material is of rare occurrence. In the same way, but not for the same reason, it may be said that the least merit of bacteriological examination is the direct detection of specific infective organisms. Where such organisms are detected the supply is, of course, to be condemned. But it must be remembered that infective organisms are not dissolved in the water and uniformly distributed over it. They are solid bodies floating in it, and as only a very small sample of the total supply is examined, they may be present in the supply and absent from the particular samples chosen. They are also in all cases accompanied by other organisms, some much better capable of growing in water; and when they reach the analyst they may be so far attenuated that they fail to develope in his media, and though present may escape recognition. The chief merits of bacteriological examination are two. On the one hand, it furnishes a factor capable of quantitative estimation by which variations in the composition of the supply may be detected. On the other hand, it enables organisms which, though themselves indifferent, are usually introduced with infective material to be detected.

It also enables us to control the working of water filters. Respecting the information that we may gain from the microscopic examination of suspended matters, it must be remembered that while we may sometimes find such bodies as epithelial scales, undigested muscular fibre, and the like, which may lead us to suspect pollution with sewage or other putrescible matter, yet in most cases of waters from towns such substances will be filtered out of the water; this will also happen in the case of well waters, so it is only occasionally that this method of examination will render assistance to the analyst.

The microscope also permits the recognition of organisms different from and of larger size than those which are known to be infective. Some of these are directly diagnostic of the sewage which is the ordinary vehicle of infective material, and where the supply has been filtered, the presence of any such larger organisms is evidence that the filter would have been unable to arrest the more minute organisms of infective disease, and that the protection intended to be obtained by the filtration has at least, for the time being, been illusory.

There is no great difficulty in performing the operations involved in water analysis, but the power of correctly interpreting the analytical results is only to be attained by very considerable amount of training and practice.

A satisfactory drinking water should be practically free from organic matter, and should neither contain nor have the power of dissolving poisonous metals, and should be free from excessive hardness. Regarding the first of these requirements, freedom from organic impurity, it was clearly recognised as dangerous to drink water polluted with excrementitious matter long before the precise nature of the danger was known.

Water is a compound of hydrogen and oxygen; the composition of pure water is as follows: by weight, oxygen, eight parts; hydrogen, one part; by volume, oxygen, one part; hydrogen, two parts. Up to the close of the eighteenth century water was considered to be an elementary substance, until its compound nature was demonstrated by Cavendish.

Water is a clear transparent fluid, colourless, but of a blue colour when seen in bulk. Below 0 deg. Cent. it freezes and crystallises in rhombohedra, and in six-sided prisms. At 100 deg. Cent., and Bar. 30in., it boils, having a vapour possessed of the same elasticity as the air. Vapour density, compared with the air, 0·625; compared with hydrogen = 9.

Water attains its maximum density at 4 deg. Cent.; specific gravity of ice, 0·94. Increased pressure, of course, raises the boiling point, as does also the presence of solids in solution.

In this series of articles, we propose dealing with the subject under the following headings:—

Classification of Natural Waters.
Physical Examination.
Chemical Examination.
Bacteriological Examination.
Sources of Pollution of Potable Waters.
Interpretation of Analytical Results.
The Character and Purification of Various Water Supplies.

The term pure cannot be applied to natural waters in its strict sense, but only relatively, since absolutely pure water does not exist in nature. All potable waters are contaminated with impurities to a greater or less degree. Owing to the remarkable solvent power possessed by water, the number and variety of substances which it can take into solution greatly exceed that of any other liquid. In addition to its great solvent power for many saline and gaseous bodies, it has considerable solvent power for many of the constituents of the rocks and strata composing the earth's crust. We may classify the constituents and impurities of natural waters as follows:—

Gaseous.—Carbonic acid, oxygen, nitrogen.

Solids (*Mineral*).—The carbonates of calcium and magnesium, sulphates of calcium, magnesium and sodium, chlorides of sodium and potassium, silicates.

Solids (*Organic*).—The products of the decomposition of animal and vegetable matters.

In addition to these, waters are liable to contain more or less insoluble and suspended matters, consisting of mineral matters, such as sand, clay, oxide of iron, chalk, &c., or of living and dead vegetable and animal matters consisting of algæ, moulds, bacteria, hairs, cellular tissue, fibres, insects, infusoria, epithelial scales, fæcal *débris*, &c.

Natural waters can be divided into five classes:—

Rain water.—This includes all water derived direct from the atmosphere, such as rain, snow, hail, and dew.

Surface water.—Waters derived from lakes, ponds, rivers, and streams.

Subsoil water.—Waters percolating through the

soil or rocks, at no great distance from the surface, and lying between it and the impermeable stratum.

Deep well or artesian water.—Waters obtained by means of borings at a considerable distance from the surface, and coming from below the impermeable stratum.

Sea water.—Generally speaking, we may arrange the various sources of supply of potable water in the following order with regard to purity:—

Rain water (collected under proper conditions).
Deep spring and artesian well water.
Upland surface and moorland waters.
Subsoil water (if collected distant from any source of pollution).
River water.
Land springs.
Surface water from cultivated lands.

RAIN WATER.

This is the purest form of natural water, if collected under proper conditions in the open country. Rain water contains only a trace of solid matter, and is therefore perfectly soft; but it contains frequently large quantities of ammonia, together with traces of nitrates and nitrites. The traces of solid matter are, of course, derived from the dust and other matters contained in the atmosphere. The rain water from the neighbourhood of large towns is very impure, containing as it does large quantities of soot, sulphurous acid, and other products of combustion.

The rainfall, which in the first instance is derived from the ocean by evaporation, is the original source of all our water supplies. The amount of rain falling in the London district averages less than 25in. in the year, but this gradually increases in other parts of the country till in some excessively rainy places, such as in North Wales, Cumberland, and the north-west of Scotland, it is greater than 75in. annually. Let us consider what 1in. of water means. If an acre of land were covered with water to the depth of only the tenth part of an inch, that layer would weigh more than 10 tons: thus 1in. of rain is ten times that amount; in fact, very nearly 101 tons. A rainfall during the year of 25in. corresponds to 2525 tons of water per acre.

Rain water should be caught upon properly prepared artificial surfaces made of slate or cement, and the first runnings should be separated by means of a Roberts separator. Rain water owing to its soft character has a great tendency to act upon leaden pipes and cisterns, becoming charged with this poisonous metal. In districts near the sea, rain water will be found to contain very appreciable amounts of chlorides. The River Pollution Commissioners in their report give a lengthy table of analyses of seventy-eight samples of rain water, and of eight samples as ordinarily collected and stored in tanks. The following are the averages of their results:—

	(In grains per gallon.) Fresh rain water.	Tank water.
Total solids	2·76	16·8
Chlorine	0·004	0·78
Hardness	0·42	7·9
Nitrogen as nitrates	0·43	0·78
Free ammonia	0·035	0·08

Where rain water has to be collected from the roof for drinking, it may be necessary to calculate how much can be expected from this source. To take an example, if the rainfall were 24in. per annum, and the roof (which should be slate or tiles) were 60ft. by 20ft., we should in a year get 60ft. by 20ft. by 2ft., or 4800 cubic feet, or 28,240 gallons, theoretically. In practice, however, the loss due to evaporation is considerable; and to obtain the water fit to drink it would be essential to employ a rain-water separator, an ingenious arrangement which discards the first few gallons of roof-washings, and after the roof has been well cleansed the rest of the shower is diverted into the store tank for use.

In the above case, if we imagine the cottage to contain six persons and that one-third of the water is lost, we shall have 18,826 gallons per year, or about 8·6 gallons per head per day—not a very liberal allowance.

Where rain water is to be collected for use, the keeping of pigeons is, for obvious reasons, a very undesirable practice.

(*To be continued.*)

WIMBLEDON SEWAGE WORKS.

We referred in our last issue in a brief report to the successful meeting of the Municipal Engineers' Association held at Wimbledon on the 30th ult. The opportunities offered to the members of inspection of works in progress were considerable, and of more than passing interest. Not the least interesting of these were the sewage works of the Wimbledon Council, which have been often referred to as being carried on with a considerable measure of success, notwithstanding that the greater portion of the farm is covered with stiff clay. It appears, however, that in many respects Wimbledon might with advantage copy the more modern systems of sewage treatment so successfully adopted by other towns, and with profit to themselves. To particularise we refer to the unscientific construction and working—in the light of our present knowledge—of several acres of ballast filters which are evidently copied from the Friern Barnet filters, designed by that eminent engineer Mr. Baldwin Latham, some ten years ago, and which he is now discarding, we believe, for the most modern system of treatment, and to which he has become an adherent.

The efficiency and work of the Wimbledon filters is, it appears to us, seriously impaired by the mode of application of the sewage, and by covering the ballast with the clay soil transferred from the farm lands, which not only prevents the necessary access of air into the body of the filter, so essential for bacterial development and purification, but also clogs the surface and reduces the rate of working to a very serious degree without producing any correspondingly increased purification of the effluent. The Council are also encumbered, like so many other Councils who have embarked in sludge-pressing, with the accumulation of sludge which has no marketable value, and it is proposed to destroy it in a refuse destructor which is about to be erected—a somewhat circuitous and costly method it cannot, we think, be gainsaid.

Altogether we are reluctantly obliged to come to the conclusion that Wimbledon is scarcely abreast of the times in its system of sewage disposal, and its representatives would do well to learn what other towns, such as Manchester, Leeds, Croydon, and numbers of others are doing in regard to bacterial purification of sewage.

TYPHUS, TYPHOID, AND ENTERIC.

By Edward F. Willoughby, M.D.

It was unfortunate that Louis, when insisting on the specific difference between true typhus and that form of fever in which, amid a great diversity of other phenomena, a definite lesion of the intestines was always present, and which, though known by a number of more or less trivial names, had hitherto been generally confused with typhus, should have selected the name of typhoid, or like typhus, for a disease that, as he rightly maintained, was in its etiology, pathology, and phenomena wholly unlike it. The designation enteric, expressing a fact, that of the inflammation of the enteric glands is in every way unobjectionable, and ought to supersede all others. But while in this country, in France, and Italy the older designation "typhoid" holds its ground in the popular language, and to a great extent, too, in that of the profession, the Germans, who certainly are not under ordinary circumstances averse to word building, whether with materials of home or of foreign origin, adhere with strange pertinacity, inconsistent with their usual scientific habits of thought, to the old nomenclature, at the cost of continual confusion and misunderstandings. In German statistics typhus stands for enteric fever, though in medical works, when it is necessary to distinguish between them, the one is called "fleck typhus," *i.e.*, spotted typhus, and the other typhus abdominalis or ileotyphus, as if they were still looked on as varieties of the same disease. This confusion is now infecting other languages for the usual appellation of enteric fever in German being simply "typhus," the bacillus discovered by Eberth and Gaffky is *B. typhosus*, and it is thus commonly designated by English bacteriologists, though the name should be reserved for that of true typhus, which may at no distant date be identified, as the bacillus of the plague has been within the last few years. This would reduce the German nomenclature to a dilemma, to avert which by an international agreement to use the names typhus and enteric only, retaining typhoid solely as an adjective descriptive of the well-known aggregate of symptoms frequently observed in pneumonia, septicæmia, and other febrile states, as well as in the specific fevers generally, would be a worthy achievement of the next International Congress of Medicine.

THE MANCHESTER REPORT ON SYSTEMS OF SEWAGE PURIFICATION.

(Continued from page 484.)

The iron-water station is situated below the liming station, and about 300 yards from the precipitation channels. It comprises sheds for storage of proto-sulphate of iron, with engines, boilers, and pumps for lifting water into mixers, also distributing pipes for conveying the iron solution into the sewage. In this station there are two 6-horse power Robey horizontal engines and locomotive boilers, driving shafting, wash mills, iron mixers, and rotary 6in. water pumps, &c.

Near these works are a superintendent's house, and twelve cottages for those workmen whose presence on the works is necessary. There is a light railway with two locomotives and wagons for conveying coal, lime, and iron from one part of the works to another. The establishment, including liming station, &c., extends over an area of 83 acres 2 roods 27 poles. It was completed in July and August, 1889, at a cost of £430,834 12s. 9d., to which must be added the cost of the engines and other machinery, amounting to £42,567. The number of workmen engaged averages 198.

In the treatment of the sewage, the requisite quantity of lime water (nearly four grains to one gallon of sewage, equivalent to ¼ ton of lime per million gallons, or 38 tons per day) is first discharged into the sewage as it flows past this station in the three culverts. The allotted amount of solution of proto-sulphate of iron is added (about one grain per gallon, making nine tons daily), then the sewage with its dose of chemicals flows into the precipitation channels, which were first constructed on the intermittent system, that is to say, when a channel was full it was allowed to be quiescent for a short time to allow precipitation of the sludge. The clarified effluent was carefully drawn off through the telescopic weirs into the old reservoir, and thence to the river through the nine channel outlets previously described. When it was necessary to remove the sludge from any channel, the large penstocks to each channel were closed, and the supernatant effluent was drawn off by the telescopic weirs, regulated from the lever house, until the sludge was reached. The sludge was then run off through a culvert into the sludge store chamber, and was lifted by centrifugal pumps for further consolidation in the sludge settling channels. The settled sludge, which contains between 87 per cent. and 92 per cent. of moisture, is run off as required into a store under the engine-house, and is pumped through a main along the jetty to the sludge boats, or may be run into a still lower store under the settling channels should there be more than the boats can discharge at sea through unforeseen delay.

Sludge vessels.—The first sludge vessel was built by the Naval Construction and Armaments Company, of Barrow, at a cost of £16,353. It arrived in the Thames at the end of June, 1887, and was named the Bazalgette. This vessel was found to work satisfactorily, and a second, with certain improvements, was ordered from the same builders. The following is a complete list of the vessels now found necessary for the disposal of the sludge :—

Name of Vessel.	Horse-power on Trial.	Length.	Breadth.	Depth.	Moulded Depth.	Cost.
		Ft. in.	Ft. in.	Ft. in.	Ft. in.	£
Bazalgette ..	900	230 2	38 2	13 8	14 6	16,353
Barking ...	1150	232 3	38 2	15 0	15 6	24,875
Binnie	1251	232 1	38 2	13 8	14 6	26,500
Barrow ..	1025	232 1	38 2	13 8	14 6	26,500
Belvedere ...	1094	232 1	38 2	13 8	14 6	26,500
Burns ...	1136	234 0	38 2	13 8	14 6	23 750

The sludge is delivered to the vessels through telescopic sludge-loading pipes, the inner and lower ends revolving upon a hollow trunnion, which allows the upper end to radiate to different levels to suit the state of the tide. The first two vessels are loaded through ordinary hatchways, and the last

four vessels are constructed with a central hopper, into which the sludge is received from the loading pipes. At the lower part of this hopper, four rectangular valves are placed, each governing the inlet to one of the four compartments into which the sludge tank is subdivided by a longitudinal and thwartship bulkhead. Each subdivision carries approximately 250 tons of sludge. Each compartment is about 61ft. 6in. long by a maximum width of 19ft., and is about 8ft. high. The bottom of the tank when empty is about 9in. above the light load line, and each vessel discharges her cargo by gravity. The minimum time taken to discharge 1000 tons through the eight valves is six minutes. Between the bottom of the tank and the bottom of the ship, a distance of about 6ft., is an air space to give the ship the requisite buoyancy; the sludge is discharged through this space by means of tubes. Forward of the sludge tanks the crew's place is formed, with berths for the seamen on one side of the ship and firemen on the other, and the space between this and the bow is occupied by ship's stores, chain locker, fresh-water tank, rope locker, and paint-room. Below the crew space and stores a water-ballast tank is formed, holding about 170 tons of water, which is pumped in or out by the ballast pump in the engine-room as required. Abaft the sludge tank is a stokehold containing two multitubular boilers, having together a heating surface of 2800 square feet, working at a pressure of 150 lb. per square inch, and the coal bunkers, which contain between 40 tons and 60 tons of coal. Further aft is the engine-room, containing two twin triple-expansion engines, each having steam cylinders 15in., 23in., and 35in. in diameter, with a stroke of 2ft. The engines indicated together about 1000-horse power on the trial trip. The engine-room contains also centrifugal circulating pumps, feed pump, 2in. feed-water make-up, lathes, &c.

Abaft the engine-room is the tunnel used for the screws and lockers for engine stores; above this are the officers' quarters and mess-room, and steward's pantry. Between the officers' quarters and the stern are battened lockers and a bath-room; below is a small water-ballast tank, which, if filled, immerses the screws deeper in the water when the ship is light. On deck forward is an anchor deck, lamp-room, steam windlass, mast and derrick loading hopper bridge; below is a room for the quartermaster's steam steering engine, a saloon containing two state-rooms, galley, and coal shoot; and above the boiler casing are two fresh-water tanks, which contain three tons of fresh water for supplying the boilers. There is a fire service, with six screwed unions for attaching hose supplied from the ballast pump, for use in case of fire, and for washing down the decks and sludge tanks. The arrangement of the Burns differs from that of the three earlier vessels, chiefly in the captain's room being on deck, and by being fitted with electric light, the dynamo being in the engine-room. Each ship is manned by a crew of twenty-three officers and men.

The ships convey the sludge to that part of the estuary some miles beyond Southend or Shoeburyness known as the "Barrow Deep," where it is distributed over a length of eight miles to ten miles in the open sea. Although the sludge can upon emergency be discharged in six minutes, in practice one hour is occupied, during which time the vessel is steaming ahead at her usual speed of 10 knots, thus distributing the sludge over a large area.

Soon after the completion of the precipitation works at Barking, it was found that the sewage would have to be screened on account of the large amount of floating substances passing through the tanks and flowing off with the effluent water. In July, 1890, the contractors commenced a filth hoist over the three lines of sewers at the liming station, in which are machinery and appliances for raising and lowering large iron cages or screens. These are duplicated, one being down whilst the other is raised and cleared. There is a refuse destructor with two cells, to burn the rubbish from the screens. These works were started on the 21st July, 1891, and cost £8488. The destructor has been much used since that time with the assistance of coke breeze, but the quantity obtained exceeds that consumed by the destructor, and a barge load per week has been removed down the river for use on agricultural land.

A small but not unimportant addition to the Main Drainage Works at Barking may be mentioned, namely, the artificial filter, which is generally known as the coke-breeze filter, and was the outcome of certain experiments made on smaller filters in 1892. The experimental work in connection with these filters has been published, and the results are generally known. It may be here explained as a bare statement of fact that the filter composed of coke breeze gave the best results. As the works are situated near the Beckton Gas-works, where large quantities of breeze and cinders are produced, and as it was found that these materials could be obtained alongside the Council's works at a cost of 3s. per ton, making two cubic yards, it was determined to make a filter of them with a superficial area of about one acre. This filter was constructed for the Main Drainage Committee by Mr. Crimp in 1893 at a cost of about £1494 2s. 5d. It consists of 3ft. of what is known as pan breeze or cinder, with a layer of gravel at the top 3in. in thickness intended to act as a weighting material.

Advantage was taken of the experience gained in working the smaller filters, and arrangements were made for the filter to be charged with effluent from the precipitation channels. The effluent can then be kept in contact with the filter for any required length of time, the purified effluent then flows off by a channel into the Thames, and the filter is again charged. As is well known, the purification of the effluent is effected by means of organisms which establish themselves in the filter and the amount of purification effected depends upon the length of time the effluent is allowed to remain in contact with these organisms. In practice it is found that a purification of about 78 per cent. of the dissolved organic matters can be effected with a contact of about two hours. The filter is worked day and night for six days of the week in periods of eight hours. In each period the filter is charged, the time occupied being about one hour, the effluent remains in contact for two hours, whilst the remainder of the time is occupied in drawing off the filtrate. The volume dealt with per twenty-four hours when the filter is in operation is 1,000,000 gallons, and, so far as present experience goes, the filter is apparently capable of continuing its function for a considerable period of time. This filter indicates that if it should ever become necessary to further purify the effluent generally as now discharged into the Thames, the object sought

to be attained might be accomplished by means of filters of the kind referred to.

The above coke breeze filter, which had a depth of 3ft., is now being raised by the addition of another 3ft. of coke breeze, so that its full depth will be 6ft., so as to give greater capacity for the organisms for further bacteriological experiments which are shortly to be commenced by Dr. Clowes, the chemist of the Council, the enlarged capacity entailing a further expenditure of £1500, making a total since its inception of about £3000.

The additional 3ft. in depth has all the coke breeze carefully screened, so that there is no fine dust, and none larger than 1in.

BARKING OUTFALL WORKS.

Description of samples.—Sewage, December 22nd, 11 a.m.—Contains greyish-brown suspended matter; has strong sewage smell. Effluent, December 22nd, 11.30 a.m.—Brighter in appearance than the sewage; contains dark suspended matter; strong, almost putrescent smell.

Analytical Numbers (*in grains per gallon*).

Oxygen Absorbed, 4 *hours.*

Sewage, shaken sample	4·51
,, settled ,, ...	3·32
Effluent	3·69

Oxygen Absorbed, 3 *minutes* (*Incubator test*).

	Before incubator.	After incubator.	Per cent. increase.
Sewage, settled sample ...	1·19	3·24	170
Effluent	1·34	2·27	120

Both samples became very foul.

Ammonia—

Free and Saline.

Sewage, shaken sample	1·85
,, settled ,, ...	1·75
Effluent	3·10

Albuminoid.

Sewage, shaken sample	·86
,, settled ,, ...	·42
Effluent	·64

Chlorine—

Sewage	13·2
Effluent	12·2

Remarks.—The sewage and effluent being taken so nearly at the same time cannot, of course, strictly represent one another. The incubator test shows the effluent to be of a highly-putrescible character, and the amount of albuminoids present is large. The sewage is chiefly of a domestic character.

Barking filter.—A sample of the medium from the coke breeze-filter was taken and examined. It was found to contain a considerable amount of organic matter capable of giving off ammonia when distilled with alkaline permanganate. On washing out with water about 5 per cent. of fine earthy material could be washed away from the coarser portions. The material had an inoffensive, earthy smell.

Barking sludge.—A sample of sludge from Barking was found to contain 89 per cent. of moisture.

(To be continued.)

BROSELEY.—The Local Government Board has refused to sanction the loan of £2750 in respect of a water supply for the town, on condition that four gallons per head per day was not sufficient.

HOW WOLSEY OBTAINED THE WATER SUPPLY FOR HAMPTON COURT.

AN interesting piece of history was published in last Saturday's *Surrey Comet*. We are told that as long ago as the sixteenth century, Coombe was noted for its fresh water springs, and when the great Cardinal Wolsey built Hampton Court Palace he determined to bring his supply of drinking water from Coombe. An elaborate and very successful method was employed for collecting the water from the various springs on the hill. There were three principal conduit houses, which still exist, one on the estate of Sir Douglas Fox, which is called from this circumstance "Coombe Springs," and two others on or adjacent to the estate of Mr. Middleton Campbell. By means of a number of underground carriers or feeders, the water was conveyed from the springs to these conduit houses, whence it flowed in separate pipes to a point not far from Norbiton Railway Station, where a junction was effected.

From this point the water was taken direct to the Palace through a lead pipe 2¼in. in diameter, which ran at a depth varying from 3ft. to 6ft. in front of what is now St. Peter's Vicarage, across the Cambridge-road, and in a straight line to the Fairfield, which is crossed, proceeding thence through Knight's-park, beneath the Hoggs Mill stream, and through Woodbines-park to the river. Here a considerable dip was necessary to take the pipe under the Thames, after which it was an easy matter to lay it through Home-park to the Palace. The water from Coombe formed the sole domestic supply for Hampton Court Palace for nearly 350 years, and was only discarded about thirty years ago.

There were two circumstances which chiefly influenced the Authorities in abandoning the Coombe supply. The increase of building on the Kingston-hill had the effect of polluting some of the sources of the supply, and it was anticipated that with a considerable addition to the number of houses in the future there would be further pollution. Another difficulty was that the barges which came up to Kingston, when they dropped anchor in the Thames used frequently to grapple and damage the lead pipe, which led to the occasional failure of the supply. Consequently a new supply of drinking water for the Palace was obtained from a branch of the river Colne, formerly known as the Cardinal's River, but now called the Queen's River. The intake is at Hampton, where the water undergoes filtration, and is thence pumped to the Palace.

By order of the Commissioners of Works, the old lead pipes between Coombe and Hampton Court Palace, which have been buried ever since the year 1520, have recently been taken up. It says much for the honest workmanship of our ancestors that these pipes were found to be in perfect condition, and very few of them had any trace of wear and tear. They included some of enormous length, as much as 200ft. being found without a joint. These old pipes are of great value, because they were made at a time when the method of extracting the silver from the lead had not been discovered, and the substantial nature of the pipes may be gauged from the fact that they average about 11 lb. to the foot lineal.

Owing to the great development of building on

the route of the pipes, it has been of course impossible to recover the whole length that passes through Kingston, as a good deal of it is covered with bricks and mortar, but the undertaking has proved a decidedly profitable one for the Commissioners of Works, who will be some hundreds of pounds in pocket by it. Incidentally, it may be mentioned that the old red-brick plug-house, which for so many years was an eyesore to people crossing the footbridge from Grange-road to Denmark-road, has now been demolished.

HOSPITAL EXTENSION AT LEAMINGTON.

THE foundation stone of the new wing of the Warneford Hospital, Leamington, was laid on Thursday, the 5th inst., with full Masonic honours, by Lord Leigh, Provisional Grand Master of Warwickshire, assisted by Bro. G. Beech, D.P.G. Master, and the officers of the Provincial Grand Lodge. The new wing is part of the original design for the extension of the hospital, and was last year adopted by Leamington as the local scheme for the commemoration of the Queen's Diamond Jubilee. The new structure, for which Messrs. Young and Hall, London, are the architects, will be built on the pavilion principle. The cost of the contract is £6760, and the greater part of this sum has already been provided.

The new wing will accommodate thirty-two additional patients, but the number of beds in the hospital will not be increased to this extent, as room will be found in the new wards for some of the patients who are at present treated in the old buildings, where the hygienic conditions are not wholly satisfactory. When the new wards are completed the entire capacity of the hospital will be increased to 125 beds. This, it is considered, will be ample for the requirements of the district for many years to come. The ceremony commenced with the opening of the Provincial Grand Lodge at Guy's Lodge, at the Town Hall, and subsequently a procession formed and proceeded to the site of the new buildings.

After a short address by Lord Leigh, Mr. J. R. Jeafferson proposed his health, and said his lordship's ideal of pleasure was to throw himself heart and soul into every scheme for the benefit of his tenantry and every one of his fellow countrymen. They were indebted to Lord Leigh, not only for his presence at the stone-laying, but for the assiduous care and interest he had always displayed in the hospital. Lord Leigh responded briefly, and proposed the health of the Mayor of Leamington, which was received with musical honours, and concluded the proceedings.

National Registration of Plumbers.—At a public meeting held under the auspices of the District Council for Edinburgh and the East of Scotland for the National Registration of Plumbers, at Edinburgh on Thursday, the 5th inst, Sir James Russell said with regard to the Plumbers' Registration Bill that every effort would be made to have it passed through Parliament. It was, however, an unfortunate thing for the public health, not to speak of the plumbing craft, that its passage through Parliament was so difficult.

QUARANTINE.

By Captain W. G. ROMERIE, Sanitary Inspector, Port of London.

QUARANTINE! To what numberless thoughts this word gives rise, what a cloud of tragedy has environed it since its first inception as the *guardien du pays*. How its memories awaken all the horrors of disease and pestilence, and, to the initiated, its cruel barbarities and anomilies. Unfortunately, although medical science has exposed its absurdities, this measure of the middle ages is still enforced in some of the *soi-disant* civilised countries, and even in some of our own Colonies. Reviewing the various pestilences which have visited Europe, dating from the plagues of 1345—50 and 1665, and to subsequent visitations, it would appear that disease has not been arrested in its course by any system of quarantine. It is true that since the year 1665, the visitations, in each case, have been less severe in their ravages; still the amelioration was more likely due to the spread of civilisation in all its phases than to any other cause.

Quarantine from time immemorial has been a one-sided measure, and has pressed most heavily on the great shipping industries of the maritime world, and proved the greatest hindrance ever known to commerce. Moreover, quarantine in its broadest sense, was never intended to be inhuman in its principles, but since its introduction the stigma of inhumanity has followed it through all its phases. To us in this country, where quarantine is a thing of the past, we can look down with no small measure of pride, and point out benefits to other nations. In taking the initiative, in banishing a measure which has done so much injury, we have been driven to relax the port regulations by force of circumstances. The great sanitary reform brought about by the Public Health Acts has instituted a state of security which is no idle dream, and the Infectious Disease Notification Act imposes a certain obligation on the community to enforce its enactments. Of late years the tendency has all been towards the modification, and eventually the total abolition, of quarantine.

By a succession of international conferences, held particularly in reference to cholera, Europe has been gradually brought to follow the lead of England and Germany. The success of this country in defending itself from cholera in 1892 and 1893, together with the calm reliance of the German Government on similar enlightened principles, produced a strong impression on the instructed intelligence of other lands, and the Venice Conference on Plague, held last spring, sounded the death knell of quarantine in Europe. Practically speaking, since 1872 quarantine has been a dead letter so far as Great Britain is concerned, and by the introduction of a short Act of Parliament entitled the Public Health Act, 1896, the old and effete Quarantine Act of 1825, and subsequent Acts modifying or extending its statutes, were swept away. Every vessel arriving from a foreign port by day is required to hoist her colours, and every vessel arriving after dark is required to exhibit a white light over the bows on reaching the boarding station. Article 25 provides that "the master of every ship infected with cholera, yellow fever, or plague, shall when within three

miles of the coast of any part of England or Wales cause to be hoisted at the masthead, or where best seen, a large flag of yellow and black borne quarterly, and shall keep the same displayed during the whole of the time between sunrise and sunset, and no persons other than an officer of Customs (or a person acting in the execution of this order) shall leave such ship until after such visit of the officer of Customs as mentioned in Art. 2, or until after the visit of the Medical Officer of Health, in pursuance of Art. 8. The officer is also empowered to detain an infected vessel, and order the master forthwith to moor or anchor the vessel as he so directs." Art. 3, "Whilst the ship shall be so detained no person (other than an officer of the Customs or a person acting in the execution of this order) shall leave the same." Art. 5, "Such detentions by the officer of Customs shall cease as soon as the ship shall have been duly visited and examined by the Medical Officer of Health; or, if the ship shall upon such examination be found to be infected, as soon as the same shall be moored or anchored." Under this order the sick are to be landed, and the vessel disinfected, to the satisfaction of the Port Medical Officer of Health, who is also empowered to detain the vessel until this been carried out. Art. 15 states, "No person on board such a ship as is mentioned in Art. 12, who has not been certified as required by that article, shall be permitted to land, unless he satisfy the Medical Officer as to his name, intended place of destination, and intended address. The Public Health Act, 1896, also provides a penalty of £100 for any breach of this Act, and a continued one of £50 per day.

This, then, is a brief summary of the regulations in force in this country. The medical and sanitary inspection, as carried out by the Port Sanitary Authorities generally, has proved of immense benefit to this country. Another great feature is that no restriction is placed on merchandise coming from infected places, and when we take into consideration the large amount of Indian imports that have come into this country since India was declared infected, it may be assumed that contagion or infection carried by cargo does not appear to exist. The modifications in the drastic quarantine regulations at Malta, so frequently issued in the past, very probably have been brought about by the influence of the Colonial Secretary. I must say, owing to these very stringent measures, a considerable amount of trade has been diverted from this industrious little colony. It is a far cry from England to that of the less salubrious climate of Mauritius and its dependencies. At different times within the present century small-pox and cholera have committed great ravages in the larger islands, but a decided improvement has set in. Judging by the elaborate quarantine regulations in force it would appear that there was a great deal of truth in the inference that the inhabitants of these islands believe that all visitations of epidemic diseases have been transmitted by vessels. Quarantine to these people has become almost a superstition.

I must refer to the wreck of the fever-stricken ship Traveller, on the Island of Rodriques, in February, 1897. About a week before sailing from a Java port an able seaman died, suffering from Java fever, the master being then apparently ill. The next death took place two weeks later, so it may be assumed that Java fever was prevalent on leaving. The mate died then, and within a few days five more of the crew died, also the captain. The responsibility then devolved on the second mate, together with the few remaining members of the crew, all more or less incapacitated by fever. On the 3rd February they made Rodriques, and anchored off Port Mathurin, flying signals of distress. They waited, but no assistance came, and fearing that their vessel would be wrecked, Mr. Ritch, the second mate, decided to take his crew on shore. A boat was launched by him and the two convalescent seamen, into which the captain's wife, Mrs. Christie, and her baby were lowered, together with the sick men. When near the shore the magistrate and a number of others rushed down to the water's edge and threatened to shoot them down if they landed, so they had to row back more dead than alive. No assistance was sent. The same night the Traveller was wrecked. Fortunately she did not go to pieces then. The Rodriques people sent a boat the next morning, and conveyed the crew to an uninhabited sand island, and kept them there for twenty-two days, living in huts made of leaves. The doctor came off in about a fortnight, and examined the shipwrecked crew through a pair of binocular glasses. Two men died at this place. As the monsoon was setting in, the sand island would likely be covered by the sea, so they were removed to the mainland. "The Rodriques people allowed the cargo salved to be landed, and therefore their aversion to the shipwrecked crew could not be explained." The district magistrate of Rodriques admitted that the delay in sending off assistance was the cause of the loss of the vessel. Too little regard has been paid to that noble seaman, Mr. Ritch, in bringing his vessel safely to port under such sad circumstances; and there are few gallant deeds in the annals of the mercantile marine which stand out in such bold relief as this instance of British pluck and endurance.

Another instance at Port Louis, in February, 1894, bears fitting comparison in point of barbarity with the above narrative. A British steamer arrived to coal. No sickness was reported on board, but she was quarantined because one death from sporadic cholera occurred at Rangoon during the week previous to her departure. During the coaling the captain fell down the hold. A report of the accident was at once made to the Port Authorities. After sixteen hours he was seen by a doctor. He died soon after admittance to the hospital on shore. During the early part of 1892 a steamer arrived in Table Bay from England with typhus fever among the steerage passengers. She was visited by the Health Officer, who, having received all particulars, ordered the master to remain in the bay, saying he was not in quarantine, but refusing pratique. Typhus fever was not an infectious disease within the meaning of the Act, but a day or so afterwards the Act was amended to meet the difficulty, and the ship was then placed in quarantine. As the discharging and loading necessitated employing labour, all the men so employed had to remain on board until pratique was granted, which was twenty-one days after the sick had been landed. Nothing was done to the passengers' baggage which came from the steerage, the seat of infection. The strangest anomaly was the fact of the passengers being allowed to land,

but the crew, among whom no sickness had occurred, were not permitted to do so until after pratique was granted. Judging from the reports issued by the Canadian Health Authorities, it would appear that sanitary reform was making good progress in the larger towns, and, although the change is marked in the province of Quebec, no apparent modification in the quarantine regulation at the mouth of the St. Lawrence has taken place, but, on the contrary, they are if anything more stringent than ever.

The case of a liner, bound from London to Montreal, in 1893, is a case in point. About a week after leaving London a trimmer was taken ill with small-pox, and isolated. On arrival thirty-five miles below Quebec, all hands, including the sick man, were mustered to pass the doctor. The doctor detected the sick man, and the steamer was ordered to an anchorage. The patient was removed to the quarantine hospital, and when the disinfection of the ship had been carried out, the whole of the crew were located on Grosse Island, taking bedding, clothes, and cooking utensils with them. In the meantime the crew of another ship came down from Montreal and took over charge ten minutes after the others had left, got under weigh, and proceeded to Montreal. About September, 1892, a different state of things was being enacted in New York, which attracted the gaze of the whole civilised world. I refer to the case of the Normannia and other vessels. It is not necessary for me to tell over again that story of misery, stupidity, and inhumanity, but it may be enough to say that, notwithstanding all that was done by way of inflicting suffering on the helpless passengers and crews, the cholera was not after all kept out of the place.

The States within the yellow fever zone are in constant dread of that disease, and frequent changes take place in the regulations. Dr. Collingridge stated "that yellow fever perhaps presents a stronger case against quarantine than any other disease. In addition to its uselessness, it is in this disease that the greatest danger arises from its exaction." Shipowners should, under the circumstances, be on the alert against quarantine restrictions, and I think the London Chamber of Commerce can supply some valuable information on this matter. During the months of June and July, 1896, sweeping charges were made by shipmasters at the port of Savannah against the drastic quarantine regulations enforced there. Captain Hammond said he arrived at the quarantine grounds on June 6th, and was kept waiting several days. While waiting he was informed by letter that the vessel had been chartered to load at Savannah. He was detained four days before he was allowed to come up to the quarantine station, notwithstanding the fact that he had a clean bill of health, and that there was no sickness on board. Captain Hammond complained that the bi-chloride solution, used in washing down the inside of his vessel, was likely to corrode the iron. He said that a lot of clothing had been ruined by the disinfecting chambers. The sleeping quarters at the station were insufficient, he said, and in bad condition. There were only sixteen bunks. He had twenty-one men. No sleeping places were provided for the officers. The report of the Sanitary Board exonerated its port Medical Officer from the charges made against him, and further stated that the other charges had not been proved. "While quarantine has been considered very onerous and a hindrance to commerce," the Commission says, "it calls attention to the fact that Savannah only quarantines against places; it does not quarantine against Jamaica and the Isle of St. Thomas, as other Southern ports do."

The Commission calls attention to the fact that the rules observed at the Savannah quarantine are the rules laid down by the United States through the Marine Hospital service. At Jacksonville quarantine is so strict that very few foreign vessels visit the coast. Had I time to relate the history of quarantine in the Brazils, I could portray some of the saddest events it is possible to think of. Since the year 1850—the year the yellow fever is supposed to have been imported into the Brazils from New Orleans—it has claimed an alarming number of victims from the ranks of our British seamen. Ship after ship has been lying at Rio de Janeiro and Santos totally swept by this disease, and crew after crew have been sent from this country at great expense to bring the vessels home. If we take into consideration the impoverished condition of the country, brought about by continual political unrest which prevails throughout the Republic, and where martial law is conspicuous by its frequent appearance, it is doubtful whether any improvement in the near future is likely to take place. The case of the British steamer Olympo affords a melancholy example of the selfishness which is practised by some so-called civilised nations, when there is any dread of epidemic. The Olympo did not take the cholera with her, but contracted it while in quarantine at Rio, where the Authorities declined to supply food to the animals that were dying of starvation on board, or medicine or provisions to the men who afterwards fell ill. No assistance was given her, and the cholera was left to burn itself out. A desperate attempt to force an entrance into the harbour and solicit help from foreign gunboats failed. The whole case is one of the most sickening and shameless barbarity. Mr. F. P. Hanson, Argentine Consul, in referring to the regulations, which are based on the time-honoured precept that "prevention is better than cure," says, "It should be remembered that our experience in the Argentine Republic of foreign epidemical diseases has been such as to oblige us to take every possible precaution against the introduction of yellow fever, cholera, &c., to our shores. In 1871 a few passengers from a yellow fever-infected country landed surreptitiously at the city of Beunos Ayres, brought on an epidemic which cost us the lives of 18,000 inhabitants. In 1886 a cholera-infected ship from the Mediterranean caused an outbreak of cholera, in which several thousands perished." As to sickness occurring on board in port he further says, "No sick person may be kept on board or removed from a ship except by authority of the Health Officer, nor may any medical man go on board for professional purposes without giving notice to the Port Sanitary Authority, and being accompanied by one of its officers, except in cases requiring surgical assistance." To place a healthy ship in quarantine coming from an Indian plague-stricken port for twenty days, and eight if she comes from a port in the Mediterranean where cholera has taken place, is, to say the least, an enormous penalty to pay. Another cause of complaint among shipmasters frequenting these ports is the fact that no medical

assistance can be obtained without permission of the Port Sanitary Authority. Flores Island, the quarantine station of this Republican State, is about twenty miles from Monte Video, and has been for years the cause of much complaint on the part of those who have undergone detention there.

A captain writes home and says:—"The arrangements on Flores Island are most scandalous, and the charges for enforced detention extravagantly high." He then relates one of his experiences. "On one occasion," he says, "I arrived there in a Pacific Steam Navigation Company's steamer, about an hour after a Messageries Maritime mail boat. The doctor having visited the latter vessel first, ordered five days' quarantine for all passengers landing. He then came on to us and would have treated us similarly, only it so happened that we had six wild bulls on board, intended for bull fighting, and having instructions that these were urgently wanted, he granted us free pratique. After which he was of course obliged to go back to the French steamer and treat her the same." It is, of course, reasonable to expect that, during the prevalence of an epidemic, more than ordinary precautions must be taken to minimise, as far as possible, the danger of importing the malady, but to impose even observation on a healthy ship, although coming from an infected district, is, to say the least, unnecessary and uncalled for. In the words of the sanitary reports, "so dreadful was once the condition of the Navy that in the year 1726, when Admiral Hosier sailed with seven ships of the line to the West Indies, he buried his ship's company twice, and died himself from a broken heart." Again, Anson's "Voyage Round the World from 1470 to 1744," forms one of the most lamentable histories of human calamity through disease ever known.

The Merchant Navy was, if anything, in a worse plight than the sister service. Improved education is making headway among the officers of the merchant service. Besides, the sanitary inspection carried out at a home port has instituted some of the principles of hygiene, with the result that cleanliness in British ships is becoming daily more noticeable. Bills of health originated, Dr. Collingridge tells us, with the Turkish merchants about the sixteenth century, and became general throughout the maritime world. Of late years, however, their value as a health passport is not quite so apparent. This has arisen, no doubt, from the fact that telegraphic communication is far more speedy and reliable now-a-days than in those days of slow locomotion. In nine cases out of ten bills of health, clean or foul, are treated as mere waste paper. A useful purpose might be served if the official log-book, which is virtually the ship's bill of health, was made more use of. For instance, at the present time, all cases of illness, injury, and death, besides the medical treatment, have to be recorded therein. Would it not, then, be of more practical use if this book was *vised* at every port by the Health Authorities, with remarks as to the health of the crew, details of disinfection, if any, and sanitary condition of the ship?

MANCHESTER.—No cases of small-pox have been reported in Manchester for a little over a year.

Sanitary Inspectors' Associations.

LONDON.

AN ordinary general meeting of the Sanitary Inspectors' Association was held on Saturday at the Carpenters' Hall, London Wall, E.C. Mr. T. G. Dee, the chairman of the Council, presided, and among those present were Messrs. H. Alexander, E. Lightfoot, S. C. Legg, Barth, Pettit, W. W. West, Ashdown, Middlewick, W. Wilkinson, Jordan, A. Duck, Taylor, Thornley, Nurcombe, Leah, and Mr. E. Tidman, C.E., the hon. sec.

MEMBERSHIP.

The Association considered at some length the applications for membership of Mr. A. Ellenden, Assistant Sanitary and Street Inspector of Kensington, and Mr. J. H. Rowe, London County Council lodging house Sanitary Inspector.

The CHAIRMAN ruled that Mr. Ellenden, having been appointed Assistant Sanitary Inspector by the Kensington Vestry, was qualified for membership, and he was duly appointed by eleven votes to ten; Mr. J. H. Rowe was held to be unqualified except as an associate member, and his application was accordingly referred to the Council for consideration. Several other members were appointed.

DOUBTFUL APPOINTMENT AT STOKE NEWINGTON.

The HON. SECRETARY reported that he had written to the Local Government Board, the London County Council, and the Stoke Newington Vestry as to the proposed appointment by the latter Authority of a Surveyor and Chief Sanitary Inspector, such appointment being held to be contrary to the spirit of the Public Health (London) Act, 1891. The Public Health Committee of the London County Council had written to the Local Government Board in support of the view taken by the Association, but from reports in local newspapers it appeared that Mr. J. G. Smith had recently been appointed by the Stoke Newington Vestry as Surveyor and Chief Sanitary Inspector, subject to his passing the examination of the Sanitary Institute. Mr. Tidman added that this appointment was clearly not in accordance with the Act, as a Sanitary Inspector must be qualified at the time of appointment.

After discussion, it was resolved to again communicate with the Local Government Board on the subject.

THE CITY SCANDALS.

The HON. SECRETARY stated that as it was rumoured that the Sanitary Inspectors of the City were concerned in the recent bribery scandals, he had written to the newspapers on the subject. The Medical Officer of Health of the City had also written stating that the officers of his department were not in any way concerned with the scandals, which were confined to the Street Inspectors.

The action of the Hon. Secretary was approved.

DANGERS TO HEALTH FROM DEFECTIVE SANITATION.

Mr. W. WILKINSON (Altofts, Yorks) read a paper on "Dangers to Health arising from Defective Sanitation." He said that defective sanitation comprised badly-designed structures, inefficient work-

manship, and defective materials, and these produced, among other evils detrimental to health, typhoid, enteric, and continued fever, with diphtheria. In old houses box drains would be found running through the basement, and these permitted sewer gas to escape into the cellar where food supplies were stored, and thence insidiously penetrate into all parts of the dwelling. Drains should be laid at right angles from inspection chamber, with a true inclination from sewer to house connection. The correct capacity in all cases should be considered, as this was the first factor for the effective working of all drains, and complete disconnections should be rigidly enforced in all outlets. The hurry to cover in drains and avoid tests was to hide defective work, and he had often advocated that no man should be permitted to lay a drain or any work in connection therewith unless he possessed the necessary qualification proved by registration or certificate obtained from a board of examiners consisting of expert and practical men. Each board of examiners should contain one or more members elected by the Sanitary Inspectors' Association. This was a safeguard against bad work, a protection to architects, builders, and themselves, and primarily for the public at large. In his opinion, the Cecil gully or trap was more effective, there being little or no room for a deposit. Much had been said for and against the intercepting trap, but everything depended upon the size of it and the construction of the drains. Hand-flushed closets should be condemned. The safety of a household depended upon the proper fixing of appliances. The dangers arising to health from bad workmanship were many; and even the best appliances might be made insanitary or imperfect by careless fixing. He was opposed to surface-ventilating grates, as well as the dangerous practice of connecting from the sewer into manufacturing chimneys. Wherever a gas ventilating shaft or sewer air destructor might be fixed, the inhabitants residing in close proximity would imagine there were dangers arising from it. The opinion had been clearly expressed by sanitary engineers that the present system of taking ventilating shafts outside houses is altogether wrong, as unless they are run up to a great height they practically act as conductors of disease. In short, there was only one way to deal with sewer gas, and that was to destroy it absolutely, which could be done by burning it in sewer gas destructor lamps. It might be urged that this applied only to such sewers as are not disinfected, but this was shown by Dr. Klein, in his report on "The Behaviour of the Typhoid Bacillus and of Koch's Vibrio in Sewage," to be erroneous. Dr. Klein showed that the typhoid bacillus was infinitely more active, and showed incomparably greater vitality in nitrate sewage than in pure sewage. This practically meant in dealing with the problem of sewers that when we flush them with disinfectants we are laying down food for our deadliest enemy—typhoid. On the other hand, if in place of putting in disinfectants destructors were inserted along the line of sewers, and the gas driven off by the decomposition of the sewage drawn out and destroyed, we should in all probability have what is at present the great desideratum, the sewage, however foul when it entered the conduits, would at the outfall be innocuous. When the expert craftsman had completed his work to the best of his knowledge and skill, under the strictest supervision, there remained for the household to faithfully observe the simple instructions, and to use the appliances with cleanliness and care. Failing this, the best sanitary work would be useless. He hoped the Authorities of cities and towns would recognise the difficult position in which a Sanitary Inspector was placed in having to perform the dual office of Drain and Sanitary Inspector, more especially when they take into consideration the many cases of infectious disease which they also had to inquire into and deal with at the same time. There was great advantage in appointing a Drainage Inspector, similar to a Building Inspector, who could then properly devote his time to the details of his duties. The healthfulness of a town, city, or district, was taken according to its immunity from fevers, and Mr. Wilkinson quoted at length the opinions of eminent authorities on the subject, and the conclusion at which he had arrived was that sewage ought to be treated in a more efficient manner than it is generally to-day. No town ought to be allowed to turn its sewage into tidal water. The habits of people with respect to cleanliness, and more especially their care to protect their habitations from pollution. was a clear indication of the progress of civilisation and sanitation. It was a deplorable proof of the want of information and of due appreciation of the importance of the circumstances on which the improvement of the moral as well as the physical condition of the population depend, the existence of filth in houses, the prevalence of dirty habits among the people, and the efforts to remedy or mitigate the attendant evils, should so often be treated with contempt, as if the subject were of no consequence or fitted only to excite disgust. It was incumbent on Local Authorities to show by the way they dealt with the problems before them that they themselves believed in the necessity of cleanliness and sanitation, and that the laws they had to administer were the practical fulfilment of the primitive laws for personal and household purification.

Mr. H. ALEXANDER (Shoreditch) moved the hearty vote of thanks to Mr. Wilkinson for his paper; this was seconded by Mr. MIDDLEWICK (Kensington), and after some remarks from Mr. THORNLEY and the CHAIRMAN, was carried with acclamation.

Mr. WILKINSON having acknowledged the compliment, the usual private conference was held, after which a vote of thanks to the Chairman for presiding closed the meeting.

NORTH-WESTERN AND MIDLAND.

THE opening meeting of the twelfth session was held at the Liverpool Royal Institution on Saturday last, the 7th inst. Mr. Wm. Stansfield (Manchester) presided, and there were present Messrs. W. Bland (Urmston), E. Worrall (Penmaenmawr), E. Roberts (Carnarvon), T. Waters (West Bromwich), W. Urquhart (Crewe), J. Mort (Lynn), N. Coates (treasurer), H. H. Spears (hon. secretary), and a number of other members from Liverpool and surrounding districts, Manchester, and West Bromwich.

Messrs. Job Robertshaw and J. Heslop, of Man-

chester, were elected members, and some additional nominations were also received.

Short discussions, initiated by Mr. J. Mort (Lynn), took place on the liability of Local Authorities to remove garden refuse placed in ashpits, and also as to the applicability of the model bye-laws to certain drainage problems.

At the close of these discussions Mr. Wm. Stansfield, Chief Sanitary Inspector, Manchester, delivered the Chairman's annual address.

Mr. Stansfield having expressed his thanks to the members for the honour conferred on him by reason of his election to the chairmanship, proceeded to make a very interesting comparison as to the greatly improved position occupied by the Sanitary Inspector of to-day compared with an Inspector appointed in 1875. When they considered the methods adopted to recruit the small army of sanitary soldiers at the time of the passing of the 1875 Act, one was struck with the fact that either the men whose duty it was to fix the salary to be offered had not risen to the importance of the subject, or that some other motives were at work. In those days it was not advisable to enforce the provisions of the Public Health Acts if Inspectors wished to retain their positions, and for these and cognate reasons satisfactory progress was out of the question. The Inspector was in many instances regarded as a necessary evil, and this was the utmost recognition he could obtain. As the years passed on Inspectors had gradually gained for themselves a more assured position ; hitherto inactive Local Authorities had moved on, if only slowly, to the betterment of sanitary administration. He considered that the rise of the Sanitary Inspector practically began when associations of sanitary officers were founded. Originally such associations were stigmatised as existing solely for the interests of the Inspector ; but it was now becoming recognised that the educational value of these movements had good results, not only upon the Inspector individually, but also the Local Authorities served and the public generally. Dealing with the increased number of duties devolving on Inspectors, Mr. Stansfield gave a list of some twenty Acts of Parliament passed since 1875, every one of which had added to his already multifarious occupations. The amount of additional work thrown upon Sanitary Inspectors by the Infectious Diseases (Notification) Act was almost incalculable, and but for the marked energy and enthusiasm displayed, the continued growth of other branches of sanitary work must have been checked. Mr. Stansfield favourably commented on the work done by the Sanitary Institute in the education and training of Inspectors, but considered that it was in the highest degree essential that at least two years' practical training as assistant to a Sanitary Inspector holding office should be the qualification necessary for all applicants for appointments as Inspectors. It went without saying that the young Inspector of to-day had many advantages over older Inspectors in point of education and training, but there were many opportunities even for those more advanced in years to acquire information and knowledge. In his opinion, by far the greatest assistance was rendered by the sessional meetings of the Inspectors' Associations, where sanitary problems were constantly under discussion, and the Inspector who wilfully isolated himself from his *confrères*, relying only on his personal experiences, laboured under most serious disadvantages. Mr. Stansfield reviewed in detail the peculiar advantages offered by the Association of which he was chairman, and referred to the almost phenomenal progress which had taken place within the two preceding years, concluding a most interesting address with a forecast of the work of the new session.

A well sustained discussion ensued, the following taking part therein :—Messrs. Bland, Mort, Waters, Coates, Spears, and Grimsley. Mr. Stansfield replied on the discussion, and the meeting terminated.

The Council of the Association has unanimously adopted the following resolution :— "That the Council of the North-Western and Midland Sanitary Inspectors' Association expresses its hearty approval of the Sanitary Inspectors' Appointment and Superannuation Bill, 1898, and requests the Council of the Sanitary Inspectors' Association to furnish the necessary information as to the probable date of introduction of the Bill, in order that no opportunity may be lost of furthering its interests."

SOCIETY OF PUBLIC ANALYSTS.

At the monthly meeting, held at Burlington House, Dr. Matthew A. Adams, Medical Officer of Health for Maidstone, read a paper on "Water Supply in Relation to the Recent Epidemic." In the discussion which followed, Dr. J. W. Washbourn, Dr. Childs, Dr. Pakes, and Mr. Stoddart alluded to the bacteriological aspects of the matter, it being admitted by Dr. Washbourn that although bacteriological examination, like chemical analysis, often showed definite evidence of animal or sewage pollution, it could hitherto in no case be said to have resulted in the actual detection of the typhoid bacillus, even in water, clearly responsible for the dissemination of typhoid. The matter was also discussed, mainly from the chemical standpoint, by Mr. Otto Hehner, Mr. Allen, Dr. Voelcker, and Mr. Cassall. The President of the Society (Dr. Bernard Dyer) referred to the assistance often afforded by bacteriological methods of examination, however imperfect they might yet be in the confirmation of chemical results in the analysis of water, saying that the water analyst who did not familiarise himself with and make use of bacteriological methods deprived himself of a material aid in interpreting the admittedly more definite results of purely chemical analysis.

Obituary.

DR. MACKINTOSH, OF CHESTERFIELD.

Dr. Angus Mackintosh, Medical Officer of Health for the Chesterfield Union, died recently, at the age of sixty-five, at his residence in Gladstone-road, Chesterfield. He had been ill for only a few days, suffering from bronchitis, quinsy, and erisipelas of the head and face. He had held the post of Medical Officer for twenty-six years. Dr. Mackintosh was a native of Blair Athol, and first practised in Cornwall. He was the author of several medical treatises.

General News.

HOME.

WHYTELEAFE.—Diphtheria has again broken out in Whyteleafe.

NORWICH.—A large isolation hospital is to be built. In the meantime temporary accommodation will be provided.

BELPER.—At the next meeting of the Rural District Council a report on the Holloway water scheme will be submitted.

GLOUCESTER.—The Council has decided to apply to the Local Government Board for £15,000 for the new infectious diseases hospitals.

CHIPPENHAM.—The Rural District Council has decided to purchase a scarifier at an estimated cost of £95, with an additional £20 for fitting.

PENISTONE.—The Urban District Council has decided to borrow £2400 on the sewerage and waterworks account, and also to purchase a new crane.

FOLESHILL.—The Local Government Board has recommended the Public Loan Commissioners to lend the District Council £1360 for waterworks at Bedworth.

HEMSWORTH.—A sum of £800 is to be spent for road repairs, and the Local Government Board has sanctioned a loan of £800 for alterations at the hospital.

BARKING.—A Local Government Board inquiry has been held recently respecting an application by the Urban Council for sanction to borrow a sum of £8250 for the erection of public baths.

TAMWORTH.—The Town Council has passed a resolution in favour of applying to the Court of Chancery for an injunction to restrain the Birmingham Authorities from polluting the river Tame.

MONMOUTH.—The seal of the Town Council has been affixed to a surrender of a lease of some cottages which had been hired as an infectious diseases hospital, and which the Mayor (the Right Hon. Lord Llangattock) wished to purchase and re-model for that purpose, and then present to the town.

BELMONT.—Owing to the continued outbreak of infectious diseases in Belmont, near Bolton, it has been decided to have a thorough investigation made into the sanitary condition of the whole township. Mr. Codling, A.M. Inst. C.E., of Manchester, has been instructed to make the inspection and report thereon.

LONDON.—Dr. W. Collingridge, the Medical Officer of Health for the Port of London, in his half-yearly statement, reports that of 14,795 visits of inspection 12,174 (82·28 per cent.) were made on vessels carrying the British flag. Since 1892 11,467 vessels have been medically inspected, or an average of about 2050 per annum. During the last half-year thirty cases of infectious disease have been discovered and dealt with. An unusually large quantity of unsound food has been seized, including 1351 carcases, 868 pieces of beef and mutton, 60 casks of horse beef, 695 cases of condensed milk, and 219 crates of bananas.

SCARBOROUGH.—The death-rate at Scarborough during the last quarter was 18·5 per 1000, against 15·4 in the corresponding quarter of last year. Respiratory diseases accounted for 35 deaths, heart disease for 22, and influenza for 20. The zymotic rate was 0·4 per 1000, against 0·7. There were 269 births during the same period.

LANCASHIRE.—Reports were submitted at a recent meeting of the County Council showing the great progress made in the technical teaching of the various arts and industries, and of agriculture. Emphasis was laid on the immense value of a series of experiments which have been conducted at the experimental farm for the suppression of tuberculosis.

HEYWOOD.—At a special meeting of the Town Council last week a resolution was confirmed authorising the Corporation to obtain permission to introduce into the Heywood Corporation Water Bill, now pending in the House of Lords, additional provision, providing for the constitution of a Joint Water Board, consisting of representatives from the boroughs of Heywood and Middleton, to manage the water undertaking for the two boroughs.

TAMWORTH.—Dr. Fausset, Medical Officer of Health, in his annual report, just issued, states that the deaths of infants under one year of age within the borough during the past year was equal to a death-rate of 193 per 1000, against 137 per 1000 last year. This is the highest infantile mortality registered within recent years. In many cases death had been brought about by carelessness, either in regard to exposure to cold or ignorance. This distressing subject is one of vital importance to the well-being of the inhabitants, and every effort should be made to discover and remedy the causes which keep up the rate of infant mortality so abnormally high, in spite of all the sanitary measures which have hitherto been adopted with the object of improving the health of the community and lowering the general death-rate.

MALDENS AND COOMBE.—The principal portion of Dr. Davison's report at the last meeting of the Council dealt with the nuisance at the Beverley brook. He stated that complaints had been received as to the offensive condition of Beverley brook, and he had, in company with the Surveyor, made an inspection of the brook. The stream gave off foul and offensive smells, and for the last fifteen months the householders in the neighbourhood had complained that the smells penetrated the closed doors and windows of their homes. The occupiers of land adjoining the brook also made complaints. The smells might produce disease, and the state of the brook was causing an interference with the watercourse, owing to the accumulation of matter. These things could be dealt with under the Public Health Act. He was convinced, after having made an inspection with Mr. Davison, that the nuisance was not caused in Coombe, but that it came from an adjoining district. The arrival of hot weather would increase the nuisance. As the responsible Authority had failed, after fifteen months, to prevent the pollution of the stream, so deleterious and damaging to the district, he (the Medical Officer) considered that the time had come when steps should be taken to remove the stigma on the sanitary reputation of the district, which was in all other respects one of the healthiest in the county.

KINGSTON-ON-THAMES.—The Town Council, at its last meeting, resolved to make application to the Local Government Board for its sanction to an additional loan for bath purposes, estimated to amount to between £1100 and £1200, in respect to the additions made subsequent to the original contract.

GATESHEAD.—The Board of Guardians has resolved to present a petition against the Vaccination Bill at present before Parliament, "praying that any rules and regulations to be made by the Local Government Board respecting vaccination shall not have legal force or effect until the same have been submitted to and approved by Parliament."

CHELSEA.—At a recent meeting of the Vestry Dr. Louis C. Parkes, the Medical Officer of Health, presented an important report, in which he stated that during the past five months an epidemic of measles had been in progress in Chelsea, which up to date had caused the deaths of some seventy persons in that parish, the victims being chiefly young children under five years of age. Dr. Parkes urged the Vestry to concur in the action suggested by the School Board for London to the London County Council that the latter body should by order schedule measles in the list of dangerous infectious diseases.

ABROAD.

COOLGARDIE.—With reference to the Coolgardie water scheme, the engineer-in-chief (Mr. C. Y. O'Connor) states that he has already cabled to England to the effect that he has been told that the seamless pipes which are being manufactured in Adelaide are a great success, and that therefore the specifications for the Coolgardie water scheme pipes must be such as to permit of this style of pipes being adopted, if it is found that they are as great a success as stated. He has intimated to the Commissioners in England that in plenty of time before the tenders are due to come in, he will go to Adelaide and see these pipes made and tested of a size such as will be needed for the work. Provision has accordingly been made that that kind of pipe can be tendered for, and of course, if found quite satisfactory, and considerably cheaper than the other types, as stated by the patentees, there is no reason why it should not be adopted.

NUWERA ELIYA.—Mr. S. M. Burrows, the chairman of the Nuwera Eliya Board of Improvement, has issued the following notice to householders:—"It appears to the Board of Improvement to be advisable to take extra precautions in the matter of the disposal of night soil, partly because another outbreak of typhoid fever would be a very serious affair for Nuwera Eliya, chiefly because the ravages of the plague in India are a warning to all towns in the East to be exceedingly careful as to sanitation. The Medical Officer and the Board Inspector will endeavour, during the next few months, to visit every house in Nuwera Eliya, and inspect the arrangement made for the disposal of the night soil. It is impossible to make exceptions and visit some houses and not others; and I am sure I may ask you to give them such assistance and information as they require when they visit your houses, for the present is a time when we must all submit to rather more stringent regulations on sanitary matters, when the neighbouring Continent is teaching us such a terrible lesson on the subject."

Personal.

MR. J. A. BEYNON has been appointed Inspector of Nuisances for the rural district of Frome.

MR. G. W. MCQUINN has been appointed Sanitary Inspector for the Holborn sanitary district.

Mr. G. COOPER has been appointed Inspector of Nuisances for the rural district of Glossop Dale.

MR. R. H. WILKIN has been appointed Medical Officer for the fifth district of Thingoe union.

MR. MAURICE COOMBE has been appointed secretary of the Newport Plumbers' Trade Union.

DR. P. L. BENSON has been appointed Medical Officer of Health for the rural district of Buckingham.

MR. D. H. ATTFIELD has been appointed Medical Officer of Health for the urban district of Watford.

MR. J. H. MARSH has been appointed Medical Officer of Health for the urban district of Little Hulton.

MR. J. FULLER has been appointed Medical Officer of Health for the rural district of Long Ashton.

MR. CHARLES DICKINSON has been appointed Inspector of Nuisances for the urban district of Prescot.

MR. A. S. RANSOME has been appointed Medical Officer of Health for the urban district of Southgate.

MR. WM. STEPHENSON has been appointed Medical Officer of Health for the rural district of Beverley.

MR. JOHN S. BRUN has been appointed Inspector of Nuisances for the urban district of Oystermouth.

DR. A. MAXWELL WILLIAMSON has been appointed to the new office of Chief Sanitary Inspector for Edinburgh.

DR. JAMES LAWRENCE has been reappointed Medical Officer of Health for Darlington for a further period of three years.

MR. JAMES FIELD, of the Health Department, Sunderland, has been appointed Assistant Sanitary Inspector to the Rochdale Urban Authority.

Sewerage Schemes.

[To MUNICIPAL ENGINEERS AND SURVEYORS.—The Editor will be pleased to receive items for publication relating to sewerage schemes projected or inaugurated, together with explanatory diagrams or photographs. The former should be drawn and lettered in black ink.]

AN additional £3000 is required to finish the Portishead sewerage scheme.

THE Local Government Board has sanctioned the application of the Farsley Urban District Council for permission to borrow £15,700, the estimated cost of the sewering and sewage disposal of the district.

THE Local Government Board has consented to a loan of £5300 for sewerage works at Oadley.

THE Town Council of Stockport has decided to apply to the Local Government Board for sanction to borrow over £50,000 for the reconstruction of main roads, sewerage purposes, and public improvements.

THE Gomersal District Council has received a draft Provisional Order from the Local Government Board empowering it to take a plot of land on the Oakwell estate for the purposes of sewage outfall. It appears that the owners of the estate had offered an alternative site, but that on the advice of the engineer to the Council it had been decided not to accept it.

AT a recent meeting of the Pontefract Town Council, the Mayor gave the result of the visit of a deputation to Exeter to inspect the septic system of sewage treatment. The sewage passes into a tank, developes bacteria which destroy it, and then consume themselves. The Council decided to adopt the system, at a cost of about £300. The existing sewage works will be used, and all that will be needed will be acquisition of septic tanks.

A LOCAL Government Board inquiry has been held at Aldeburgh with respect to the proposal of the Town Council of the borough to borrow £11,000 for the purposes of sewerage and sewage disposal. The scheme is a very expensive one for so small a population, but, when the works are completed, the engineer is of opinion that the town will be well sewered, and the sewage will be disposed of without nuisance or annoyance to anyone or the least pollution of the river Alde.

AT the last monthly meeting of the Whitby Urban District Council, the question as to the desirability of the completion of the sewerage system of the town came up for consideration. Mr. W. Brown gave an exhaustive *résumé* of the different schemes for completing the sewerage system which had been before the town during the past twenty-three years. It was finally decided that the question be referred to the Highways and Sanitary Committee for consideration and report in connection with a bridge scheme.

AFTER the ordinary meeting of the Derby Town Council last week the members met in Committee to discuss the difficulty which has arisen between the Borough and County Council in reference to the alleged pollution of the Derwent by the town sewage. A communication had been received from the County Councils, embodying certain conditions under which they are disposed to defer any legal proceedings while the Corporation continues its investigation with reference to a more perfect sewerage scheme. The Corporation is prepared to virtually accept those conditions, and the Mayor is to have a further interview with Lord Waterpark, the chairman of the Public Health Committee of the County Council, and to arrange terms to be binding on both parties.

THE Sewerage Committee of Aberdeen Town Council recently had under discussion a request by the District Committee of the County Council to be allowed a connection with the city sewers for ground at Mannofield, outside the city boundary. It was remitted to the Burgh Surveyor to report on the subject.

Lighting.

A NEW gas-testing and gas-meter department of the London County Council is to be opened shortly iu Rosebery-avenue.

THE Keighley Corporation Gas Committee is preparing to apply for a Provisional Order empowering it to supply the electric light.

THE St. Anne-on-Sea Gas Bill was before the examiners on Friday last, and it was reported that the standing orders had been complied with.

A LOCAL Government Board inquiry has been held at Bolton into an application of the Council to borrow £100,000 for gasworks extensions, renewal of mains, &c.

THE Leyton District Council has decided to adopt a scale of charging for the electric light based upon what is known as the Brighton system, under which the price per unit paid for the light varies in accordance with the average number of hours per day customers use it.

THE work of introducing the electric light into Leith was formally begun on Wednesday, the 4th inst., by Bailie Manclark. The engineer, Mr. Bryson, has not adopted the culvert system in laying the cables, but is putting them into the earth and protecting them on the top with iron plates. The cost of the whole undertaking is estimated at about £30,000.

DURING the quarter ending March 31st the Coventry Electric Light Department supplied 35,090 units of currents, as compared with 21,516 during the corresponding quarter of last year. The rentals amounted to £891 4s. 5d., as compared with £547 6s. 5d., while the number of consumers increased from 76 to 112. There had been an increase in the mileage of high-tension mains of 1255 yards, and in the low-tension mains of one mile 359 yards.

AT a recent meeting of the Morley Town Council, Mr. Robert Hammond, of London, consulting engineer, reported on the public electric lighting scheme recently inaugurated. It appeared that the amount sanctioned by the Local Government Board was £22,500, and that up to the present the Corporation had committed itself to an expenditure of £20,764, leaving a balance of £1735 10s. 2d. of the original scheme still available for mains, extensions, &c.

HAVING regard to the action of the Gas Light and Coke Company in raising the price on the north side of the Thames, the Board of Works for the Holborn district, in co-operation with the Vestries of Clerkenwell and St. Luke, has decided to convene a great public meeting in the Holborn Town Hall on Wednesday, 25th inst., to protest against such increase, and urge upon the Government to hold an inquiry into the working and management of the company. Sir Albert Rollit, M.P., has consented to preside, and will be supported by the local members of Parliament, of the London County Council, and the School Board, and many other well-known gentlemen in the North of London.

ON Friday, May 6th, without any public or formal ceremony, the longest piece of roadway lighted by electricity in England was so illuminated for the first time. The road, which runs from the fire brigade station at Hampstead, close to the heath, to Tottenham Court-road, has for a part of its length been lighted by electricity for some considerable time, and by an agreement between the Vestries of St. Pancras and Hampstead arc lamps have now been carried from Camden Town to the foot of Haverstock-hill, while the Hampstead Vestry has similarly lighted the remainder of the road in question. The length of road lighted, which runs in an almost straight line, is between four and five miles.

AT a recent meeting of the Dundee Town Council a discussion took place in reference to the question of the electric lighting of the public streets. Bailie Doig asked whether the convener of the Electric Lighting Committee was considering the extension of the electric lamps in Nethergate and Tay-street, in reply to which it was stated that the Committee had every disposition to extend both the public and private electric lamps. It was proposed that the Council instruct its engineer to prepare a comprehensive scheme for extending the electric lighting system in the public streets. Bailie Doig thought the Council was quite right in extending the system on those streets where it was aware it would not be interfered with by the tramways. Latterly it was agreed to remit the whole question to the Gas Committee for further consideration.

THE extension of the electric lighting throughout the town of Bulawayo is being continued, and it is the best proof of the local success and popularity of the new light. Mr. Meikle, the resident engineer at the electric light station for Willoughby's Consolidated—or rather the subsidiary Electric Lighting Company—reports that the light would soon be available in the suburbs. At present the house-lighting load is equivalent to about 1000 lamps, while the capacity of each of the alternate current dynamos is 1500. The two, however, would be capable, if the present system of street-lighting were abandoned, of dealing with four times the present house-lighting load, so that any extension of plant for house-lighting need not be contemplated for fully two years. Mr. Meikle is strongly in favour of the company adopting a separate system of street-lighting by means of arc lamps. Altogether the progress is very gratifying, and augurs well for the future.

THE Corporation of Glasgow will shortly be called upon to consider a gigantic scheme for supplying electric current within the whole municipal area. Mr. Chamen, the newly-appointed engineer, has submitted a report on the matter to the Electricity Works Sub-Committee of the Corporation, and that Committee has approved generally of the suggestions made. The report will next come before the Electricity Committee. The capital expenditure detailed in the report is £551,000, made up as follows :—Capital expenditure at present, £150,000 ; capital expenditure proposed in report, £396,000 ; cost of removal of Waterloo-street plant, £5000. The surest way to arrive at a low rate of charge for the supply of electric light is to make the concern as large as possible, so that the sooner the capital expenditure contemplated in the report is reached the better. Mr. Chamen therefore recommends (1) that, in addition to the £95,000 to which the Corporation already stand committed, a further expenditure of £61,000 be authorised for the Port Dundas station and mains, and (2) that an expenditure of £108,000 be authorised for the South Side station and mains.

THE adjourned meeting in connection with the proposal to introduce the electric light to Wormit was held in the Public Hall on Thursday, the 5th inst. The Chairman ruled that the meeting was called to discuss the proposal to establish electric light, and read Mr. Cowley's original circular. Mr. Balfour, of Edinburgh, made a statement which showed that the figures submitted to the last meeting were correct, and advised the meeting to start a company amongst the residents for the purpose of establishing an electric lighting station. Mr. Balfour explained that by doing so they would then be keeping the profits to themselves, and informed the meeting that there were many large companies ready to set up plant in such places as Wormit, which in the end would mean a heavy purchase price if the community at some future time wished to buy out the installation. He also said he was informed that a company could be formed in twenty-four hours, consisting of local gentlemen. In drawing comparisons of cost, he said that in Edinburgh the light cost 3½d. per unit, or equal to about 3s. 6d. per 1000 cubic feet of gas, and was 3 per cent. better light, while for motive power the price was 1½d. per unit. He estimated that 5d. per unit for Wormit would be ample, and that in course of time it would be much less. At the conclusion the following gentlemen were unanimously appointed to go on with the scheme :—Messrs. Anson Wood, Robert Kinnes, John Lawson, George Duncan, and William Cowley.

Law Cases.

DRAINAGE OF ISLINGTON.

IN the Court of Queen's Bench, before Mr. Justice WILLS and Mr. Justice KENNEDY, Mr. C. A. RUSSELL, Q.C., with whom was Mr. GWYNNE JAMES, applied *ex parte*, on behalf of the Midland Railway Company, the South-Eastern Railway Company, and the Tottenham and Hampstead Junction Railway Company, for a rule for a man-

damus directed to the Vestry of St. Mary's, Islington, requiring them forthwith to take such steps as might be necessary for the effectual drainage of their district. The learned counsel explained that a sewer vested in the Vestry ran right under a considerable portion of a line of railway belonging to the applicants. At the time that the sewer was constructed the district was practically a rural district. There were but few houses, and the sewer was then sufficient to carry off the surface water. Buildings and houses had now been erected, and the district had become an urban district, with the result that a much larger quantity of surface water than formerly found its way into this drain, arising in part from the fact that much less got away by percolation. The slope of the land was from north to south, and whenever there was a heavy rainfall the water that was unable to find its way down the drain flooded the line, and did very considerable damage. Since 1889 applications had from time to time been made to the Vestry to remedy this state of things, but up to the present time nothing had been done in the matter. He asked for a rule calling upon the Vestry to take all necessary steps to effectually drain their district, and to submit a scheme for the approval of the London County Council.

Mr. Justice WILLS said they thought that was the proper form for the rule to take, and granted the application accordingly.

ATTACK ON A LADY SANITARY INSPECTOR.

HUGH M'CARTY, labourer, 40, Blackie's-buildings, Regent-road, was summoned at the Liverpool Police-court for assaulting Miss Ethel Frances Burton, a Sanitary Inspector in the employ of the Liverpool Corporation, on the 26th ult. Mr. RUDD appeared for the complainant, and Mr. LOWNDES for the defendant. Complainant stated that her duties consisted of visiting premises and reporting insanitary conditions. She had been employed in this duty for over a year. On the 26th ult., at 10.30 a.m., in company with Miss Heald, another Inspector, she visited defendant's house. On knocking at the door she was admitted by defendant's wife. Witness was in uniform. The rooms occupied by defendant consisted of a kitchen and three bedrooms. Defendant's wife became violent, and appeared to be under the impression that witness wished in some way or other to interfere with the children. Without witness requesting her to do so, she took her into a bedroom. Defendant, who was lying on a sofa, got up and became very violent. He seized witness by the arm and dragged her into another bedroom, and ultimately snatched witness's book from her. Defendant's wife stood in the doorway, and prevented witness leaving the room for half an hour. Defendant eventually allowed witness and Miss Heald to leave the house. Miss Heald gave corroborative evidence. Complainant, in reply to the Bench, said they did not as a rule make surprise visits. Mr. Lowndes, in defence, said defendant was a man of good character, and was under some irritation at the time the ladies visited the house. Mr. Kinghorn said what he looked upon as the serious part of the case was that these ladies visited the house in their official capacity. He was sure ladies would perform duties of this kind with more delicacy than men could possibly do, and seeing they were ladies he was bound to take a serious view of the matter. He must impose what to defendant would be a serious penalty, namely, 20s. and costs.

A COSTLY CESSPOOL.

AT the Enfield Petty Sessions, Phillip J. Collins, of the Moat House, Southbury-road, Enfield, was summoned by the Enfield District Council for allowing a cesspool attached to his house to overflow on October 29th, 1897, and March 18th last. He was also summoned for £1 19s., expenses incurred by the Council in emptying the cesspool. Mr. Munro, Sanitary Inspector under the Council, said that after a request in writing, on October 15th last, he went to the Moat House and found the cesspool full and the sewage flowing back up the drain from the house. On October 29th the conditions were the same, and witness wrote to defendant, the cesspool being emptied by the Council's men the following day. On March 18th he again found the cesspool full, and it had to be emptied by the Council, the cost for both occasions being £1 19s. 6d. At Goat-lane, Wadley Wood, and some other districts, where asked, the Council undertook to clear out cesspools at certain fixed charges. The Council did not charge in the case of one cesspool because there was a temporary arrangement while the Local Government Board were considering a scheme of drainage.

In defence, Mr. Collins contended that he paid the same rates as other people, and that the cesspool was not overflowing, though he would not say that it was not above the inlet pipe. The cesspool was made under the order of the District Council, but his contention was it should not have been made, and he wrote to ask Mr. Munro why he did not stop him when he stopped Mr. Hardman. The Council, too, emptied cesspools free where they were about to have the drainage. He was now rated at over 6s. a week.

The Clerk said that was no answer.

Defendant added they, the Council, had emptied it eight times, and could not recover the cost before, because they were over time in claiming for it.

The Bench imposed a fine of 5s. and costs in each case; and the costs to which the District Council had been put, including £1 1s. towards counsel's fee, a total amount of £4 15s.

AN AMERICAN PHYSICIAN ON PREMATURE BURIAL.

(*To the Editor of* THE SANITARY RECORD.)

SIR,—In a series of articles on the subject of "Premature Burial and How it may be Prevented" in the *Medical Press and Circular*, a reprint of which you notice in THE SANITARY RECORD, April 22nd, Dr. Walsh calls attention to "the rank harvest of literature that has sprung up around the subject," and does not hesitate to declare that "the whole theory of premature burial is unsupported

by a single scientifically-proved instance." Referring to this statement, Colonel Vollum, M.D., Inspector of Hospitals in the United States, and one of the authors of the volume before mentioned, writes that "Outside of Austria and Germany neither science nor the medical profession has ever given much attention to the subject. The disclosures of these disasters (live burial) have for the most part come to light by mere chance or accident. There is little room for scientific proof under such circumstances. Even in the countries before named (where the law requires two inspections of the body, independent of the attending physician, and where every possible precaution, aided by scientific methods, are employed to prevent these disasters) the experiences of these official expert inspectors are a sealed book to the public, consequently they throw no light upon what science has done in the matter under their hands. Yet we find that the systems of inspection of the dead, with that of waiting mortuaries, which have existed in those countries for nearly a century, are being extended and perfected at the present time. This is sufficient proof that they have been found necessary to prevent living burials, which the Mayor of Munich acknowledges have occurred in his city in spite of all these precautions for their prevention."

Not wishing to trespass unduly on your valuable space, I will, with your permission, revert to Colonel Vollum's further observations on another occasion. I may observe that the American physician's interest in the subject began through his own narrow escape, having been left for burial after medical examination.—Yours faithfully, M. A.

April 30th, 1898.

Notes and Queries.

[Subscribers have the privilege of obtaining advice in this column on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed to The Editor, "Notes and Queries," The Sanitary Record, 5, Fetter-lane, London, E.C 1

Note.—If an answer be required immediately, a stamped addressed envelope must be enclosed, when we will endeavour to furnish a copy of the answer by post, as owing to the large number of queries received we cannot guarantee the insertion of a reply in the succeeding issue.

1071. — Smoke Nuisance from Pipe Manufacturer's Kilns.—"M." writes:—"We are manufacturers of sanitary pipes, our works being situated in the middle of a town, although formerly they were surrounded by fields. We have been served with a notice from the Local Authority to abate the smoke nuisance arising from our kilns within a specified time. Now, to do this means to close our works. We might possibly, by erecting shafts costing £300 or £400, reduce the nuisance from two kilns; but as these will probably have to come down within twelve or eighteen months, such an expenditure will be a waste of money. But we cannot entirely abate the nuisance except by closing the works altogether. Will you please say what powers are vested in the Local Authority to enforce the notices?"

Answer.—The Local Authority have doubtless served notice under Sec. 94 of the Public Health Act, 1875, in that a nuisance is deemed to be caused under Sub-sec. 7 of Sec. 91 of the Act. Under this sub-section "any fireplace or furnace which does not, as far as practicable, consume the smoke arising from the combustible used therein, and which is used for working engines by steam, or in any mill, factory, dye-house, brewery, bakehouse, or gasworks, or in any manufacturing or trade process whatsoever, shall be deemed to be a nuisance liable to be dealt with summarily in manner provided by the Act." There is an important proviso, however, to the section, which is as follows:—"Where a person is summoned before any Court in respect of a nuisance arising from a fireplace or furnace which does not consume the smoke arising from the combustible used in such fireplace or furnace, the Court shall hold that no nuisance is created within the meaning of this Act, and dismiss the complaint if it is satisfied that such fireplace or furnace is constructed in such manner as to consume as far as practicable, having regard to the manufacture or trade, all smoke arising therefrom, and that such fireplace or furnace has been carefully attended to by the person having the charge thereof."

1072.—Houses: Cleansing and Lime-washing: Powers as to.—"Scissors" writes:—"Is there any section under which I can proceed in regard to the cleansing of houses which the owners and occupiers have allowed to become very dirty, and in my opinion unfit to live in because of not being cleansed?"

Answer.—If the premises are in such a state as to be a nuisance or injurious to health, as defined by Sec. 91 of the Public Health Act, 1875, they may require the occupier, by notice under Sec. 94, to abate the nuisance by cleansing and lime-washing the house, if such be necessary. Or the Authority may require, under Sec. 120 of the Act, if the Medical Officer of Health certifies that the cleansing and disinfecting of any house would tend to prevent or check infectious disease, the owner or occupier to cleanse and disinfect such house.

1073. — Dairies, Cowsheds, and Milkshops Orders: Provisions as to Cleanliness, &c.—"E. W. P." writes:—"(1) What penalty (if any) is there if a dairyman or purveyor of milk does not register himself with the Local Authority? (2) If there are no regulations in the district as to dairies, &c., what power has the Sanitary Inspector for prescribing for the lighting, ventilation, drainage, and the keeping of dairies? (3) A purveyor of milk keeps the milk in churns in a front room of a small house; the room is used as a general shop. What power has the Sanitary Authority to require the dairyman to provide a proper milk-store?"

Answer.—(1) Article 6 of the Dairies, Cowsheds, and Milkshops Order of 1885 provides that it shall not be lawful for any person to carry on in the district of any Local Authority the trade of cowkeeper, dairyman, or purveyor of milk unless he is registered as such therein; and Article 3 of the Dairies, Cowsheds, and Milkshops Amending Order, 1886, prescribes a penalty of £5, and in the case of a continuing offence a penalty of £2 per day for an offence against the Order of 1885. (2) A cowkeeper or dairyman is required by Article 7 of the Order of 1885 to make provision to the reasonable satisfaction of the Local Authority for the lighting and ventilation, including air space, and the cleansing, drainage, and water supply of every cowshed or dairy not occupied as such prior to the commencement of the Order; and Article 8 makes similar provisions as regards dairies, &c, in use and occupation prior to the commencement of the Order. The Local Authority should proceed under the provisions of one or other of these articles. (3) Article 11 of the Order of 1885 provides that it shall not be lawful for any person following the trade of a dairyman, &c., to use a milkstore or milkshop in his occupation, or permit the same to be used, as a sleeping apartment, or for any purpose incompatible with the proper preservation of the cleanliness of the milk-store or milkshop, and of the milk vessels and milk therein, or in any manner likely to cause contamination of the milk therein. If the Sanitary Authority are satisfied that these provisions are not complied with, they

may, after giving the occupier reasonable notice, proceed for a recovery of the penalty provided by Article 3 of the Dairies, Cowsheds, and Milkshops Amending Order, 1886.

1074.—Rural District Councillor: Assistant Overseer Disqualified for.—"R. D. C." writes:—"Will you please inform me whether a paid Assistant Overseer in a small rural parish is disqualified from serving as a Rural District Councillor or Guardian, the said Assistant Overseer being appointed by the justices prior to Rural District Councils being formed, and his duties explicitly stated to be all the duties of an Overseer of the Poor, with the exception of the collection of the poor-rates?"

Answer.—By Sec. 46 of the Local Government Act, 1894, a person is disqualified for being elected or being a member or chairman of a Council of a parish or of a district other than a borough, or of a Board of Guardians, if he holds any paid office under the Parish Council or District Council, or Board of Guardians, as the case may be. And by Sub-section 5 of this section a person disqualified for being a guardian shall also be disqualified for being a Rural District Councillor. Inasmuch as the Assistant Overseer is, it appears, holding a paid office under a Board of Guardians, he is disqualified from being elected, and from acting as a Guardian or Rural District Councillor in the district from which he derives a salary from the Guardians.

1075.—Water Supply: Power of Local Authority to Enforce Requirements as to Quality of Water Pipes.—"Inspector" writes:—"Can you please inform me whether a Local Authority has power under any of the Waterworks Acts to enforce a certain quality of pipes and cisterns to be fitted to water-closets? The supply is constant, and the Local Authority is the water company. They have no private powers."

Answer.—The provisions of Sec. 48 of the Waterworks Clauses Act, 1847, and of Secs. 16 and 17 of the Waterworks Clauses Act, 1863, apply to the case. These provisions are incorporated with the Public Health Act, under Sec. 57 of that Act. Sec. 48 of the Act of 1847 requires that water pipes shall be of such a strength and of such material as shall be approved of by the undertakers; while Sec. 16 and 17 of the Act of 1863 prescribes that if any person wrongfully does, or causes, or permits to be done, anything in contravention of any of the provisions of the special Act, or wrongfully fails to do anything which, under any of these provisions, ought to be done *for the prevention of waste, misuse, undue consumption, or contamination of the water* of the undertakers, they may cut off any of the pipes by or through which water is supplied by them to him, and may cease to supply him with water so long as the cause of injury remains or is not remedied, &c. Although Secs. 16 and 17 of the Act just quoted relating to cisterns are not very specific as to the size and capacity of cisterns, we are of opinion that the provisions are sufficiently wide as to cover reasonable requirements of the Authority appertaining thereto, so as to prevent the undue consumption or waste of water.

1076.—Nuisances: Removal of: In Cases of Emergency.—"B. W." writes:—"Is there any power by which (1) a serious nuisance, injurious to health, such as a stopped drain, causing an accumulation of excreta to overflow the closet and premises, or (2) the existence near dwelling-houses of decomposing carcases of cattle, requiring prompt abatement, can be removed more quickly than by the usual notices by the Inspector of Nuisances and the Local Authority?"

Answer.—(1) We know of no provisions other than those contained in the Public Health Acts, whereby a nuisance from a stopped drain may be required to be remedied, and which can be enforced with more expedition than is possible by service of notice on the direction of the Sanitary Authority. An Inspector of Nuisances may, of course, send a form of intimation or preliminary notice to the person responsible for the nuisance in such cases, and upon the expiration of the time allowed in the preliminary notice, report the matter to the Sanitary Authority, and obtain their direction and authority to serve a statutory notice, with power to institute legal proceedings in the event of such notice not being complied with. (2) In urban districts the provisions of Sec. 49 of the Public Health Act, 1875, are applicable to such cases as decomposing carcases referred to, and the Inspector of Nuisances may give notice to the person to whom the same belongs, without directions from the Sanitary Authority, to remove the "offensive or noxious matter," &c., within twenty-four hours, failing which he may remove and dispose of same, and recover expenses from the owner of the matter removed.

1077. — Building Bye-laws: Erection of New Building.—"W. C. C." writes:—"Will you kindly inform me if anyone can put up a club-room in the front of my dwelling-houses, the road being only 15ft. wide?"

Answer.—This query is so extremely vague that we are quite unable to give an opinion which will be helpful to our correspondent. If he will furnish us with a block plan drawn to scale, showing the situation of the proposed club and his own dwelling-houses, and also inform us whether the district is an urban one or a rural one, and whether bye-laws as to new streets and buildings are in force in the district, we will then endeavour to assist him.

1078.—Offensive Drains and Water-closets inside Bakehouses.—"Bakehouse" writes:—"Thanks for your reply to my Query No. 1057 *re* above. Sec. 15 of the Factory and Workshop Act, 1883, says, 'It shall not be lawful to let or suffer to be occupied as a bakehouse or to occupy as a bakehouse any room or place which was not so let or occupied before the 1st day of June, 1883, unless the following regulations are complied with,' &c. I shall be glad if you will tell me what course I am to take to abate such nuisances in bakehouses let and occupied before the 1st day of June, 1883. Am I to serve notice under Sec. 91 of the Public Health Act, 1875?"

Answer.—On reference to the provisions of Sec. 15 of the Factory and Workshop Act, 1883, we find that the clause "which was not so let or occupied before the 1st day of June, 1883," was repealed by Sec. 27, Sub-sec. 2, of the Factory and Workshop Act, 1895, and the section must now be read:—"It shall not be lawful to let or suffer to be occupied as a bakehouse or to occupy as a bakehouse any room or place unless the following regulations are complied with," &c. The procedure as suggested by us in our reply to Query 1057 should therefore be followed.

Vacancies.

Assistant Borough Surveyor (Luton, May 14th).—For the Town Council. Salary £110 per annum. Mr. Geo. Sewell, town clerk, Luton.

Engineer (London, W.C., May 25th).—For the Metropolitan Asylums Board. Salary £600 per annum, with travelling expenses, office accommodation, and the necessary clerical assistance. Application forms may be obtained from Mr. T. Duncombe Mann, clerk, Chief Offices, Norfolk House, Norfolk-street, Strand, W.C.

Inspector of Nuisances (Bromley, May 14th).—For the Rural District Council. Salary £150 per annum, inclusive of all expenses. Application forms can be obtained at the Clerk's Office, 96, High-street, Bromley.

ASSISTANT SURVEYOR (BURNLEY, May 20th).—Salary £150 per annum. Town Clerk's Office.

BUILDING FOREMAN (WALTHAMSTOW, May 27th).—For the Urban District Council. Salary £3 10s. per week. Mr. E. J. Gowen, clerk, Town Hall, Walthamstow.

CITY ENGINEER (CAPE TOWN, June 15th).—For the Corporation of the City of Cape Town. Commencing salary £800 per annum. Messrs. Davis and Soper, 54, St. Mary-axe, London, E.C.

DEPUTY CITY SURVEYOR (CARLISLE, May 23rd).—For the Corporation. Salary £150 per annum, rising by annual increments of £10 to a maximum of £200 per annum. Mr. Henry C. Marks, A.M.I.C.E., city surveyor, 36, Fisher-street, Carlisle.

ELECTRICAL ENGINEER (LONDON, E., May 16th).—For the Electric Lighting Committee of the Poplar Board of Works. Mr. Leonard Potts, clerk, 117, High-street, Poplar.

ELECTRICAL ENGINEER (REDDITCH, May 14th).—For the Urban District Council. Messrs. Browning and Hobson, clerks to the Council, Redditch.

ENGINEER, &c. (HARTLEPOOL, May 24th).—For the Hartlepool Port and Harbour Commissioners. Salary £400 per annum. Mr. S. Herbert Belk, law clerk to the Commissioners, West Hartlepool.

Contracts Open.

The dates given below are the latest up to which tenders can be received.

BOSTON (LINCS.)—May 16th.—Roding, &c., Drains.—Mr. H. Clarke, C.E., Boston.

LLANTRISANT (WALES). — May 16th. — Drainage Work.—Mr. W. John, School Board Office, Llantrisant.

WARRINGTON.—May 16th. — Pipes. — Mr. Thomas Longdin, borough surveyor, Town Hall.

BLACKBURN.—May 17th. — Electric Lighting.—Mr. John McLellan, 50, Northgate, Blackburn.

ROCHDALE.—Electric Lighting.—Mr. R. A. Leach, clerk, Union Offices, Townhead, Rochdale.

BERKHAMSTEAD. —May 17th. — Sewer. — The Surveyor's Office, Shrublands-terrace, Berkhamstead.

LONDON, N.E.—May 19th.—Drain Pipes.—Mr. F. W. Barratt, surveyor to the Vestry, Vestry Hall, Churchrow, Bethnal Green.

SALE.—May 19th. — Sewering. — Chairman of the Building and Drainage Committee, 4, School-road, Sale.

To Medical Officers, Surveyors, Sanitary Inspectors, &c.—High-grade Cycles at reasonable prices for prompt cash and on the GRADUAL PAYMENT SYSTEM. Catalogue post free.—MELROSE CYCLE COMPANY, Coventry.

THE SANITARY PUBLISHING COMPANY, LTD.,
5, Fetter Lane, London, E.C.

THE WRITER OF THIS LETTER

is Mr. L. Casleton, 15, King George Street, Greenwich, London, S.E. He says:—

"I have been for years a martyr to a very bad form of headache, which attacked me nearly every day, sometimes quite prostrating me. I was advised to give up drinking tea entirely, and take Cocoa as a beverage. I decided to try Dr. Tibbles' Vi-cocoa, which I commenced taking some two months ago, and I am glad to say that since then I have been quite free from my dread enemy, headache. I feel confident that this result was brought by Dr. Tibbles' Vi-Cocoa, for I had tried numerous remedies without any success. I find nothing picks me up so quickly as a cup of Dr. Tibbles' Vi-Cocoa after I have had a stiff day's work in school. I shall be glad to testify personally to anyone what a real boon your excellent food beverage has proved to me."

DR. TIBBLES' Vi-Cocoa

is made up in 6d. packets, and 9d. and 1s. 6d. tins. It can be obtained from all Chemists, Grocers, and Stores, or from 60, 61, and 62, Bunhill Row, London, E.C.

The unique vitalising and restorative powers of Dr. Tibbles' Vi-Cocoa are being recognised to an extent hitherto unknown in the history of any preparation. Merit, and merit alone, is what is claimed for Dr. Tibbles' Vi-Cocoa, and the proprietors are prepared to send to any reader who names this paper (a postcard will do) a dainty sample tin of Dr. Tibbles' Vi-Cocoa free and post paid.

OFFICIAL ADVERTISEMENTS.

BOROUGH OF SCARBOROUGH.

ASSISTANT SANITARY INSPECTOR.

The CORPORATION of SCARBOROUGH REQUIRE a Temporary duly-certified ASSISTANT SANITARY INSPECTOR.

Salary 30s. per week.

Applications in applicants' own handwriting, stating age, qualifications, and previous experience, and enclosing copies of not more than three testimonials, and marked outside "Assistant Sanitary Inspector," to be sent in to me not later than Twelve o'clock (noon) on Tuesday, the 17th inst.

JOHN E. T. GRAHAM,
Town Clerk's Office, Scarborough, Town Clerk.
May 2nd, 1898.

COUNTY BOROUGH OF BLACKBURN.

APPOINTMENT OF SANITARY SUB-INSPECTOR.

The Corporation of this Borough invite APPLICATIONS for the post of SANITARY SUB-INSPECTOR, at a wage of 30s. per week.

Applicants must hold the certificate of the Sanitary Institute, and the person appointed will be required to devote the whole of his time to the duties of the office, and in particular to act as Workshops Inspector.

Applications, stating age, qualifications, and experience, accompanied by three testimonials, and endorsed "Sanitary Sub-Inspector," to be sent to the undersigned, not later than Monday, the 23rd day of May instant.

By order,
ROBERT E. FOX,
Town Hall, Blackburn, Town Clerk.
5th May, 1898.

SANITARY INSPECTOR.

THE VESTRY of the PARISH of LAMBETH REQUIRE an additional SANITARY INSPECTOR.

Candidates must possess the Certificate of the Sanitary Institute, and should have a knowledge of plumbing, drain-laying, and building construction.

The Inspector to be appointed will be subject to the Vestry's superannuation scheme; must reside within the parish, and, if required, in the particular district (part of the Inner Wards) which will be allotted to him; must devote his whole time and attention to his duties, and not engage in any other occupation; and must be prepared before entering upon his duties to undergo a medical examination similar to that required by the recognised Friendly Societies of a candidate for membership. He will be subject to the orders and regulations of the Local Government Board and to the existing and future bye-laws and orders of the Vestry.

Age to be not less than 30, nor more than 45.

Salary £120, rising £5 yearly to £170. No claim to a pension. Uniform will be provided.

Applications to be made in the candidate's own handwriting on forms to be obtained at the Vestry Hall, and sent to the undersigned, with copies of not more than three recent testimonials, on or before the 2nd day of June next. Original testimonials, if sent, will not be returned.

Canvassing, either personally or by letter or through friends, will disqualify.

The election will take place at the Vestry Meeting to be held on Thursday, the 7th day of July, at Seven o'clock p.m.; but selected candidates will receive notice of the day they will be required to attend at the Vestry Hall.

HENRY J. SMITH,
Clerk to the Vestry.
Lambeth Vestry Hall, Kennington-green, S.E.,
May, 1898.

SANITARY ASSOCIATION OF SCOTLAND.

EXAMINATIONS IN SANITARY SCIENCE.

Examinations for Certificates of Competency in Sanitary Science are held each year as follows, viz.:—In Glasgow in April, in Edinburgh in October, and at such other time and place as the Board of Examiners may determine.

Entrance Fee £2 2s.

For further particulars apply to

GEORGE MIDDLETON, M.A., LL.B.,
Writer, 92, Bath Street, Glasgow,
Secretary to the Board of Examiners.

A Stamped Addressed Envelope must accompany all letters requiring an answer.

SANITARY INSTITUTE EXAMINATIONS.

TUITION BY CORRESPONDENCE.

An Engineer and Surveyor (Mem. San. Inst.), Certificated Surveyor and Inspector, prepares students for these Exams. by Correspondence through the post.

Fees strictly moderate. Cramming studiously avoided.

The course of tuition is arranged so as not only to qualify the student for passing the exams., but what is of equal importance, viz., that he may become a thoroughly efficient Inspector.

On successfully passing the exams., all possible assistance and advice is given to help forward intending candidates for public offices.

Many of my old pupils are now filling positions with salaries of over £120 a year.

For terms, &c., address "C. E.," care SANITARY RECORD, 5. Fetter-lane, London, E.C.

SANITARY INSTITUTE EXAMINATIONS.

SPECIAL Corresponding Classes for the **Practical Sanitary Science,** and **Sanitary Inspectors' Examinations** of the **Sanitary Institute, 1898,** conducted by a gentleman holding appointments as Urban District Council Engineer and Sanitary Inspector, holder of three certificates from the Sanitary Institute, First-class Honour Medallist Hygiene, &c. Hundreds of successes.—For all particulars, testimonials, &c., apply Mem. San. Inst., Office of THE SANITARY RECORD, 5, Fetter-lane, London E.C.

Striking testimony to the value of THE SANITARY RECORD as an Advertising Medium.—The following, recently to hand from Messrs. Bugler and Co., of Alpha Works, Putney, makers of the well-known Inspection Eye Cover for drains, is to the point:—"We are pleased to tell you that since putting these covers, &c, on the market, our hopes have been more than realised, thanks, doubtless, in a great measure to THE SANITARY RECORD."

Notes.

Crops for Sewage Farms.

IT is commonly urged against the British farmer that he is a lethargic, conservative being who makes little progress in the development of his particular industry, and that he is slow to profit by the advances of science as applied to agriculture. This is no doubt true in great measure, and probably the influence of heredity is some palliation for it. But what can be said in regard to the management of the majority of the sewage farms in this country in relation to the crops that are grown thereon? There is, it appears, an absolute want of resource, or shall we say intelligence, in the inability to grow crops other than those introduced with the earliest sewage farm, and a repetition which is almost inconceivable. We find almost without exception that the familiar Italian rye-grass is grown more or less on every farm. In some instances cabbages, turnips, mangolds, and a few cereals are cultivated, all of which are grown by the ordinary farmer, but it is rarely possible to find any departure from this groove. Considering that Local Authorities are not usually limited in pecuniary resources, and that they are not influenced by heredity or environments, we confess there is little justification for the paucity of knowledge manifested in the cultivation of varying crops on sewage farms. We know of no reason why Local Authorities should not endeavour to assist British agriculture, by introducing to the benefit of the British farmer new crops which he has not hitherto cultivated, but which may be grown with increased profit to the Local Authority over those of the routine type. Thus, peppermint may be cultivated on a large number of farms, and this has been shown to be already possible in the case of one farm of which we are aware, viz., Sutton, Surrey, and which yielded a profit of about £21 per acre last year. There is no reason why lavender plants, the oil of which is now at an extraordinary price, may not be similarly grown; while strawberries, if cultivated and sewaged on the lines suggested by Mr. Dibdin in his article on "The Proper Use of Land in Connection with Sewage Purification," in our issue of April 1st, may not be grown with safety, while fruit trees and other classes of trees, vegetables, and even flowers, which command a good price, should also be grown. It is often supposed, though erroneously, that crops are the purifiers of sewage. As a matter of fact, the purification is effected by the nitrifying organisms or bacteria in the soil, and that purification is equally well effected without the aid of crops at all. From a commercial point of view, however, it is necessary to utilise the land, and this should be done wherever practicable to its fullest extent compatible, of course, with the proper purification of the sewage. We trust the day is not far distant when a more intelligent interest is shown in the sewage farms of the country, and when they can be looked to by the ordinary farmer for lessons which he may learn to his own profit, and that of the landowner, and to the benefit of the community at large.

Dust Collection in Camberwell.

ONE of the many public services which the London County Council performs is that of keeping Local Authorities up to their work. In some cases this is sorely needed, because the prevailing motive among local administrators is often that of undue economy, which means either inadequate or inefficient service. As far back as 1895 the Council has been pressing Camberwell to improve its system of collection of house refuse. The Vestry promised amendment, but further inquiries recently show that dust is still allowed to accumulate, and that there is other evidence of neglect. The Council's bye-laws require each Sanitary Authority to remove dust and house refuse not less frequently than once a week, and Section 30 of the Public Health (London) Act also steps in to the aid of sanitation in this respect. The result is that the Public Health Committee of the Council are recommending that proceedings be taken against the Camberwell Vestry, but before this can be done the sanction of the Local Government Board has to be obtained, though in view of the alleged serious position of affairs, there is not much doubt that this will be forthcoming.

Sanitary Inspectors as Witnesses.

CAMBERWELL appears to be in the black books of the Council in other respects, for the Public Health Committee is also submitting an important report which may have consequences of a grave nature so far as Sanitary Inspectors are concerned. Some time ago the Council took proceedings against the Westbury Dairy Company, Sumner-road, Peckham, for exposing milk to risk of contamination, which is an offence against the Council's regulations. Two Sanitary Inspectors in the employ of the Camberwell Vestry were called for the defence, and gave evidence against the Council's contention. Dr. Hamer's report, as Assistant Medical Officer of the Council, has been submitted by the Committee to show that the action of the Sanitary Inspectors was questionable, and now they desire to call the attention, not only of the Vestry, but also the Local Government Board, to the facts of the case. Whatever may be the result, there is clearly a need for determining the principle which should govern the giving of evidence in prosecutions of this kind by public officials, no matter what may be their position in the service.

Overcrowding in the East End.

THE question of overcrowding among the foreign population of the East End of London is occupying the attention of the Local Sanitary Authorities somewhat closely just now, particularly in St. George's East, and Whitechapel, which districts are the dumping-ground for alien immigrants. There is some reason for believing that the evil has been exaggerated, but without doubt there are certain streets and houses where overcrowding exists to an alarming extent at night time, when tenement houses can be found crowded to the very passages. The evil is peculiarly difficult to master, because unless a house is registered entry cannot be made between certain hours without a magistrate's order, and this order cannot be obtained without very definite sworn information. The registration of houses let in lodgings has had a good effect in keeping down any tendency to overcrowd—a tendency quite natural in areas where the rents are always rising. If districts such as those mentioned are not to become standing menaces to the health of the community, the Local Sanitary Authorities will have to be armed with greater powers than they now possess to prevent the inordinate congestion of a poor foreign population.

The Vaccination Bill.

THERE can be little doubt as to the attitude of the House of Commons towards the Vaccination Bill, after the division on the second reading. The majority for the Bill was simply overwhelming, 237 voting for the second reading, and only twenty-three against, showing a majority of 214 in favour of the measure. That is to say, that is the proportion of the House of Commons which is resolved on maintaining and enforcing the general vaccination law; though it must not be supposed that all those who voted for the second reading approve of the Bill in its entirety, in its present shape. But the broad fact for us to consider is, that, in spite of the determined opposition which the anti-vaccinationists offered to the Bill—and they certainly made the most of their opportunity, and took their full share in the debate—when they came to the division lobby they could only muster up an insignificant twenty-three who were opposed to the root principles of our vaccination law. In truth, as Mr. T. W. Russell said, after the reports of the Select Committee of the House and of the Royal Commission, the question whether there should be vaccination or not has practically ceased to exist.

Leicester's Claim for "Liberty."

LEICESTER has certainly achieved the distinction of coming pretty well to the front in this controversy. It poses, on the one hand, as the champion of liberty; but in Parliament, on the other hand, it is pilloried as the stiff-necked borough that attempts to set up its little will against the will of the nation. Mr. T. W. Russell put the matter in a nutshell when he said that Leicester had no right to set aside the decision of Parliament; and another speaker stigmatised the right of "liberty" claimed by Leicester as nothing less than the liberty of Leicester to spread pestilence throughout the land. Perhaps the town is proud of the distinction, but we may hope that with the inauguration of a new policy a healthier feeling will set in. And the policy of the Government is quite clear. They hold that the new lymph has removed all objections to vaccination on account of the danger, and therefore they are firm that the law must be enforced. The new Bill will not really enlarge the law, but it will enable the Local Government Board to see that the law is carried out. In taking this line, they now have the satisfaction of knowing that they have at their back, not merely the most enlightened scientific opinion, but also the unhesitating mandate of the House of Commons.

"A Century of Vaccination."

As if to indicate that the anti-vaccination party is still full of life and vigour, we have almost contemporaneously with the second reading of the Vaccination Bill the publication of a book bearing the above title, reviewing the past history of the controversy. The author, Dr. Tebb, certainly puts his case very ably and skilfully, and makes the most of the various arguments against vaccination. For example, he compares the death-rate from small-pox since the introduction of vaccination with that which preceded Jenner's reform, and he draws the inference that the decrease is very much less than we should have expected, considering all that has been claimed for vaccination. Again, he compares the decrease in small-pox with that in typhus and typhoid, and he argues that the decrease in the case of small-pox, in spite of vaccination, is not nearly so marked as in the case of other infectious diseases. But it would not be difficult to show the fallacy underlying some of these arguments. Nothing is more misleading than statistics when placed in certain lights; so much depends on the periods selected, and many other conditions, that it is possible to marshal figures that lead to the most opposite results.

The Plague in India.

It is gratifying to observe a very marked decrease in the mortality from the plague in Bombay. The number of deaths during the past week was only 138, as compared with 263 in the preceding week. The death-rate from all causes was 44·04 per 1000, as compared with 53·66 in the last return. These figures are encouraging, and if the mortality maintains the same ratio of decrease, we should before long be able to record the end of the pestilence. But, in the meantime, it is unsafe to prophesy. It is very satisfactory, however, to hear that Professor Haffkine's treatment of plague patients is being attended with the most excellent results. The mortality under his system of inoculation is said to have been reduced by 90 per cent., and it would be strange if such a successful illustration of the powers of modern science in combating disease were unable to impress the native mind. We observe that a case of plague, or suspected to be the plague, has occurred at Suez; but it appears to be a solitary case, and as the patient is recovering, and all prophylactic measures have been taken to prevent the spread of the disease, there is little occasion for alarm.

Phosphorus Poisoning in Match-making.

The attention of the Home Secretary has been drawn to a case of phosphorus poisoning in Bryant and May's well-known match-making factory, which appears to indicate a grave neglect of duty on the part of the proprietors. If it had stood alone, it would not have called for much comment; but Sir Mathew White Ridley states that the inquiries which have been made reveal systematic neglect on the part of the firm to comply with the obligations incumbent on them to report cases of phosphorus poisoning. The case to which we have referred is considered by the Home-office so serious as to justify a prosecution of the firm. The industry of match-making is attended with peculiar dangers, and, that being so, the first care of the employers should be the health and safety of their workpeople. It is a matter for regret that a firm of the standing of Bryant and May should be judged wanting in this prime duty.

Corporal Punishment in Prisons Bill.

The discussions in the Grand Committee on Law of the House of Commons on the question of corporal punishment under the Bill promoted by the Home-office for the reform of prison administration, resulted, as we anticipated, in the adoption of a modified clause, under which such punishment is to be limited to cases of mutiny, grave personal violence, and the like. Some members of the Committee, including several of the Irish members, made a strenuous effort to secure the total abolition of corporal punishment, maintaining that the present opportunity of making this reform was one that should not be lost, as such an opportunity was not likely to recur for many years; but the Home Secretary could not see his way to adopt this course. He promised, however, to consider the feasibility of holding some kind of judicial proceedings before the ordering of corporal punishment.

The Prison Dietary.

Several members of the Committee, with the view of informing themselves at first hand as to the actual state of our prison administration, have under the authority of the Home Secretary visited a good many prisons, and have inquired for themselves into the questions of dietary and prison labour. It is understood that the result of their investigations has impressed many of them, including several supporters of the Government, with the conviction that the present system is unnecessarily harsh and severe in many respects, and especially in relation to prison labour and prison diet; and it is probable that their views will have considerable influence in inducing the Government to make some considerable concessions. Indeed, Sir Mathew White Ridley has already given an undertaking to reconsider the question of the dietary.

The Liquefaction of Hydrogen and Helium.

The scientific world was thrown into a great state of excitement last week by the announcement that Professor Dewar, of the Royal Institution, had at last succeeded in liquefying hydrogen and helium. The event is regarded as one of the very highest scientific importance. Many attempts have previously been made to liquefy hydrogen, but hitherto without success, the great difficulty being the extraordinary degree of cold that is necessary for the operation. It is difficult for the untrained mind to conceive the temperature at which hydrogen liquefies. It is not very far above that of space, or minus 273 deg. Cent. It is stated that it is the lowest temperature yet observed. To produce such a temperature very elaborate apparatus is requisite. In no place on the face of the globe is there to be found so low a temperature as in a vat in the laboratory of the Royal Institution. What the scientific results of Professor Dewar's discovery will be it would be hard to predict, but it will undoubtedly prove of enormous importance in placing a new and potent instrument in the hands of scientists which they have hitherto found lacking. All Englishmen will rejoice that the demonstration that all gases can now be liquefied adds another to the long roll of illustrious discoveries which already stand to the credit of British science.

The Rights of Private Acts.

It is no small matter for the public official to make himself thoroughly acquainted with all the public Acts of Parliament which govern the carrying out of his duties. So many overlap that much investigation has often to be made before one can really make sure of the right course to be adopted. But a far greater bother to him is the private Acts possessed by numerous companies by which they claim the right to do many things not within the privilege of the ordinary individual. A case in point has just occurred at Hampton. In carrying out some extensions of its works, the Grand Junction Water Company erected an engine-house which projected some distance beyond the building line. The Local Authority, acting under the Public Health (Building in Streets) Act, 1888, called upon the company to conform to the recognised boundary,

but this it declined to do, maintaining that the company's private Act could not be over-ridden by the one cited. Naturally the case went into Court, the counsel for the Water Company claiming that the building was necessary, and could not be put elsewhere. The company had power to erect buildings within certain limits, and, providing these were not exceeded, they claimed to be within their rights. In the evidence it was proved that even if the building was necessary, by the removal of a cottage it could have been erected just as well in a line with the houses, and this view was adopted by the magistrate. Ultimately a penalty of 1s. per day for each day the encroachment continued was inflicted, with 15 guineas costs. A case is to be stated for a higher Court.

Overcrowding in the Suburbs.

The rapid growth of some of the outlying parts of the metropolis becomes more apparent every day. If we go to the great "offshoots" on the borders of Essex and Middlesex, we find whole streets of houses being built with almost alarming rapidity. On the Surrey side of the Thames the growth is equally apparent, and what but a few years ago were green fields we now find covered with buildings. When all this expansion was first planned, we were told that by this means the wage-earning class of the community would be able to secure a house for each family at reasonable rents, and that cases of overcrowded dwellings would soon be confined to limited areas in the metropolis. But these prophecies have hardly been fulfilled. Instead of obtaining a "cheap" house, the workman finds the rents of the suburbs or outer villages are gradually becoming equal to those prevalent in London; and as a result houses intended for one family are made to accommodate two. As an outcome slums are growing up, and cases of overcrowding are frequent. No wonder we hear of an increased demand being made upon Local Authorities to adopt the Housing of the Working Classes Act, for it is only by such means that an end can be put to the constant raising of rents.

A County Laboratory for Surrey.

It is right that County Councils should bestir themselves in providing opportunities for the chemical examination of the water of the districts under their jurisdiction, as well as testing the effluents discharged into the streams and rivers. At the meeting of the Surrey County Council last week it was resolved to ask the Sanitary Committee "to consider and report as to the advisability of fitting up a laboratory at the County Hall, and the appointment of a chemist to make analyses of water, sewage effluents, or such other chemical investigations as the Council may from time to time direct." If this is carried out, great service will be rendered to the numerous Urban and Rural Councils within the county. For a nominal sum they should be able to obtain trustworthy evidence as to the condition of their water supply; and if in addition the county officials make independent examinations, there will be but little chance of such epidemics as that of Maidstone visiting the district. It would be well if every County Council in the kingdom followed the example thus set by one of the metropolitan counties. The secret of the advanced scientific practice in the United States is found in the continual investigations carried out at the various experimental stations.

Paris and its Water Supply.

An interesting variation has been made in the witnesses giving evidence before the Water Commission. At the last sitting, M. Gaston Cadoux, Chef de Bureau à la Prefecture de la Seine, and holder of other important offices, gave evidence. He told how in 1860 the municipality purchased the Paris Water Company's works for 58,000,000 f. From time to time they had added to the sources of supply at considerable cost. Paris was now almost wholly supplied with spring water, except in seasons of drought, when it was necessary to supply from the Seine also. Notice was given of the change through the newspapers and the placards. The water from the Seine was kept separate from the spring water, and it was found that the latter was more economical. The receipts did not meet all the expenditure, the balance being paid by the general revenue of the city of Paris. The municipality refused to raise the price, preferring indirect rather than direct payment. £1,500,000 of English money had been spent in providing for increased supply of better water. Save for this if the old charges had been maintained there would have been a profit. We understand that similar testimony as to the practice in other foreign cities will be given before the Commission.

Extras.

Local Authorities, and engineers also, will do well to take special note of the remarks of Major-General H. D. Crozier, at the recent Local Government Board inquiry at Hampton. There is nothing so unsatisfactory as running up a long string of "extras" in connection with any work, and the discussion of them always leads to strong feeling either in private concerns or public bodies. Of recent years the tendency has been for this item to increase, particularly in connection with sewerage schemes. Generally the excuse put forward is that "unforeseen difficulties" have arisen. But there is always the chance of this taking place, and we agree with General Crozier that a more liberal allowance should be made for contingencies. Engineers must realise that they are held responsible for these discrepancies between estimate and cost, and for their own reputation they should make the fullest investigation of a district before finally fixing their levels and quantities. For instance, we know a case at the present time, where in the original plans the laying of certain pipes was fixed in the drawing at about 9ft. below the ground, in the actual work they have had to be put at nearly 30ft. Many other expenses have arisen not provided in the estimate, but which cannot possibly be defended as "unforeseen." The orginal estimate of the scheme was £21,000 odd. If the district comes out with an expenditure of £30,000 it will be lucky. It is only for the Local Government Board to let it be known it will not sanction these "extras," and more careful estimates will be forthcoming.

LIME, MORTAR, AND CEMENT: THEIR COMPOSITION AND ANALYSES.

By W. J. DIBDIN, F.I.C., F.C.S., &c.

CHAPTER III.

THE SETTING OF MORTARS AND CEMENTS.

As already shown in the previous chapters, mortar is essentially a mixture of hydrate of lime with three to four times its weight of sand, and according to the text-books its hardening is chiefly due to the gradual conversion of the lime into carbonate by absorption of carbonic acid, known strictly as carbon dioxide (CO_2), from the atmosphere. This absorption is at first rapid, and then gradually slower. Mortars even centuries old still contain appreciable quantities of hydrate of lime. The hardening may be in some cases partially due to the formation of silicate of calcium, but the evidence of this is not very strong.

It is generally held that pure silica in the form of sand acts merely mechanically, and enters into no chemical combination with the lime. For all practical purposes this is true, but experiments have shown that in the course of several years some such action does take place to a very slight degree. In Petzholt's experiments, described by General Gilmore, he found:—

(1) That in mortar one hundred years old there was more soluble silica than in the original lime.

(2) That in mortar three hundred years old there was three times as much soluble silica as in mortar one hundred years old.

While these results may be accepted they yet leave the question open, as the slight action which had taken place was too small to throw any light on the process of hardening within the period of "setting." The degree to which lime is carbonated is also so slight within reasonable limits of time as not to warrant the assumption that the hardening properties are due to this action. Doubtless the re-arrangement of the molecules in what may be termed the initial stage of crystallisation, plays an important part, and from the fact that crystals of carbonate of lime adhere most firmly to the sand, and will stand a considerable degree of force before they can be released, it would appear that this mechanical action forms one of the most important facts in the problem.

It is well known that when lime is thrown out of solution by the process of softening water, introduced by the late Dr. Clark, the precipitated lime is generally in a crystalline form, and it is not unreasonable to assume that some such action takes place when mortar sets, the minute crystals formed adhering more or less firmly to the grains of sand according to the conditions prevailing at the moment. This action would go far to explain the cause of the non-setting of mortar made with bad or imperfectly burnt lime, old mortar, &c. If the crystallisation of the lime takes place upon the surface of a substance which in itself is friable, the resulting mass will have a power of cohesion greater than that possessed by the same substance in proportion only to the power of the lime; just as the strength of a brick wall cannot practically be greater than the strength of the bricks used, as, however hard the cement, the bricks will give way under a strain in excess of the power of cohesion of their integral parts. Hence the absolute necessity for the "grit" of mortar to be clean, free from earthy matter, and of an unfriable nature.

This crystallisation theory also explains the reason why so many different substances may be used in making good mortar—a fact which the theory of chemical combination of the component elements is altogether unable to reduce to order.

Another point is, that the modern practice of grinding all the materials for making mortar together in a mill leads to a most unsatisfactory condition of the "grit." The crystallisation theory presupposes the presence of a hard and firmly resisting number of particles cemented together by the crystallisation of the lime, whether as carbonate, hydrate, &c. If by grinding the grit to a powder these "main supports," as the particles of solid matter may be termed, of the structure are broken down to a mere dust, then the initial power of resistance to pressure which they exerted in their unground state, will be thrown away, and a useless as well as dangerous muddy mass be obtained in their place.

The character of the sand employed has also much to do with the result. I made an experiment some years back in conjunction with the late Mr. John Grant, whose work on cements is so well known and justly appreciated, in which two portions of a sample of good Portland cement was made up into briquettes with a given sample of sand. In the first the sand was in its normal state, but in the second experiment I heated the sand to redness, so as to completely oxidise the iron contained in it. The result was that the breaking strain of the briquette made with the heated sand was found to be nearly double that made with the unheated sand. Possibly, the greater combining power may have been due in some respects to an altered condition of the face of the particles of sand, in consequence of which the lime crystals adhered more firmly, and thus resisted the strain to a greater extent.

In consequence of pressure of other work the experiments were not continued, but it may be that they would form the starting point of a series which might result in valuable information being obtained.

Now that means of obtaining excessive pressures are more readily accessible than formerly it might be of value to undertake a series of experiments in which the briquettes made of various limes, cements, and sands, should be subjected to pressure of various degrees, and for various periods, and their breaking strain ascertained. Such a work might well be undertaken by a Committee of experts having the proper facilities at their disposal, as it is obvious the resources of a busy private laboratory are insufficient for the purpose.

The recent experiments on the breaking strain of brick piers made with various cements, &c., by the Institute of British Architects might very well be extended in this direction. In the course of a series of experiments undertaken by a Committee of that body, a number of piers constructed of various descriptions of bricks and cements were kept for various periods, and then subjected to heavy pressures, and the results have been published in the form of two valuable reports, a review of which will be submitted later on.

Mr. Grant, in his book, page 170, remarks, in

reference to the strength of cements, "that the cohesive varied directly as the adhesive strength of cement; that, in fact, neat cement was from three to four times the adhesive strength of any mixture of it with four or five times its bulk of sand; and on this account he was prepared to state in general terms, that cohesive and adhesive strength might be taken as equivalent to each other. For the purpose of cementing together various materials, he need hardly point out that to have strong cement or mortar was not the only thing necessary. For instance, two cubes of glass could not be cemented together, however strong the cement, so that they should adhere with the same tenacity as two bricks or blocks of stone of a porous character and rough on their faces. It would not be possible, for example, to take such bricks as were recently used for lining the subway from the Houses of Parliament to the adjoining railway station, and to cement their highly glazed china faces together so that it would require the same pull to separate them as it would to separate two stocks, wire-cut gault, Fareham red, or other porous bricks, capable of absorbing one-fifth of their weight of water. Whilst on this point, he might state that only second in importance (if second) to the strength of the cement was that of seeing that the bricks or stone to be cemented together were thoroughly saturated with water. In hot climates, like that of India, any work being built with cement should be kept wet and, if possible, under shelter during its progress, and for some time afterwards. Two bricks might be put together dry, as they came from the kiln, with the strongest cement that could be made, and if not previously soaked in water these bricks might be separated without the least difficulty, the joint being very little better than if made of dry sand. With bricks which absorbed from 1 lb. to 1¼ lb. of water it was evident that, if left to absorb this moisture from the mortar with which they were cemented, they took away that which was necessary for crystallising or setting the cement."

Mr. Grant found that "The washing of the sand seems to add about 35 per cent. to the strength at the end of a week; but at the end of a month this experiment is not so satisfactory. If not washed, pit sand in the proportion of 1 of cement to 2 of sand, the breaking weight, at twenty-eight days was 330 lb., or 46·2 per cent. above the first specimen of Thames sand, or 31·21 per cent. above the same sand when not washed.

As indicating the position of the question of the setting of cements, as brought out by the results of his very numerous experiments, Mr. Grant summed them up in the following recapitulation of the results of the tests.[1]

(1) The earlier experiments, made six years ago (1859), gave, at the end of a month, a breaking weight varying from 75 lb. to 719 lb. on an area of 2¼ square inches.

(2) A minimum test of, at first, 400 lb., and afterwards of 500 lb., was specified.

(3) During six years the average strength of 1,369,210 bushels used in the Southern Main Drainage Works has been 606·8 lb., being 52 per cent. above the standard first specified, and 21 per cent. above that subsequently adopted.

1. "The Strength of Cements. J. Grant. Page 14.

(4) The average weight per bushel has been 114·15 lb., being 4·15 per cent. above the specified standard.

(5) Portland cement has been proved to be peculiarly suitable for hydraulic works, and may be procured in any quantity and of the highest quality.

(6) Portland cement, if it be preserved from moisture, does not, like Roman cement, lose its strength by being kept in casks or sacks, but rather improves by age; a great advantage in the case of cement which has to be exported.

(7) The longer it is in setting the more its strength increases.

(8) Neat cement is stronger than any admixture of it with sand.

(9) Cement mixed with an equal quantity of sand (as has been the case throughout the Southern Main Drainage Works) may be said to be, at the end of a year, approximately three-fourths of the strength of neat cement.

(10) Mixed with two parts of sand it is half the strength of neat cement.

(11) With three parts of sand the strength is a third of neat cement.

(12) With four parts of sand the strength is a fourth of neat cement.

(13) With five parts of sand the strength is about a sixth of neat cement.

(14) The cleaner and sharper the sand, the greater the strength.

(15) Very strong Portland cement is heavy, of a bluish-grey colour, and sets slowly. Quick-setting cement has generally too large a proportion of clay in its composition, is brownish in colour, and turns out weak, if not useless.

(16) The stiffer the cement mortar, that is, the less the amount of water used in working it up, the better.

(17) It is of the greatest importance that the bricks or stone with which Portland cement is used should be thoroughly soaked with water. If under water in a quiescent state, the cement will be stronger than out of water. Table XIX. shows that cement kept in water was one-third stronger than that kept out.

(18) Blocks of brickwork or concrete made with Portland cement, if kept under water till required for use, would be much stronger than if kept dry.

(19) Salt water is as safe for mixing with Portland cement as fresh water.

(20) Bricks made with neat Portland cement are as strong at from six months to nine months as the best quality of Staffordshire blue bricks, or similar blocks of Bramley Fall stone, or Yorkshire landings.

(21) Bricks made of 4 parts or 5 parts of sand to 1 part of Portland cement will bear a pressure equal to the best picked stocks.

(22) Portland cement concrete, made in the proportions of 1 of cement to 8 of ballast, in some cases, and of 1 to 6 in others, has been extensively used for the foundations of the river wall, piers of reservoirs, and foundations generally, at Crossness and Deptford, with the most perfect success, and it is believed that it might be much more extensively used as a substitute for brickwork or masonry wherever skilled labour, stone, or bricks are scarce, and foundations are wanted at the least expenditure of time or money.

(23) Wherever concrete is used under water,

care must be taken that the water is still; as otherwise a current, whether natural or caused by pumping, will carry away the cement and leave only the clean ballast.

(24) Roman cement, though about two-thirds the cost of Portland, is only about one-third its strength, and is therefore double the cost, measured by strength.

(25) Roman cement is very ill-adapted for mixing with sand.

In conclusion, Mr. Grant, whilst recommending Portland cement as the best article of its kind that can be used by the engineer or the architect, warned anyone against its use who is not prepared to take the trouble or incur the trifling expense of testing it, as if manufactured with improper proportions of its constituents—chalk and clay—or improperly burnt, it may do more mischief than the poorest lime.

The suggestion that the adhesive powers of mortar and cement are due to a process of crystallisation in contact with a roughened surface is strongly supported by the results of Mr. Grant's experience, as he lays the greatest stress upon the necessity for the presence of an ample supply of still water. The experience with the dry brick is most striking, as it is clear that such a brick would instantly absorb the moisture in the cement immediately in contact with it, and thus deprive it of the moisture necessary to bring about the process of crystallisation.

THE CHEMICAL AND BIOLOGICAL ANALYSIS OF WATER.

SURFACE WATER.

As already mentioned, the whole of our potable water is derived originally from the atmosphere in the form of rain. Part of this sinks into the earth, and the remainder runs over the surface of the land in the form of streamlets which unite to form rivers, ponds, lakes, &c. The water as it flows over the surface takes up more or less suspended and dissolved matters, the former being found in larger amounts when the rainfall is plentiful. The wearing action of water is largely dependent on the nature of the suspended matter that it conveys down from the upper levels of the watershed. When the tributaries conveying the waters from districts of varying characters become mixed, the nature of the suspended and dissolved matters may become largely modified. When the streams from the higher levels of a watershed, more or less in the form of rapid mountain torrents, gather together to form rivers, the rapidity of the current naturally becomes slower as they reach the lower levels, and as a result much of the suspended matter is deposited. The water of streams and lakes is in part derived from springs, which in many cases come from great depths, and thus may introduce into solution substances which are not present in surface water proper.

By the joint action of air and water the hardest rocks undergo a weathering or disintegrating process. By the exposure of the surface of the rocks to the alternate freezing and thawing of the water contained in the minute interstices, the superficial layers become broken down, thus enabling the water to exercise a solvent action upon the soluble constituents, the insoluble portion being conveyed down to the lower levels in the form of gravel and mud.

The Igneous, Metamorphic, Silurian, Cambrian, and Devonian rocks, which are so largely exposed in the western parts of England and Wales, yield a very considerable amount of surface water. The water so yielded is generally exceedingly soft and of high organic purity.

Rivers are very liable to pollution, as they form the natural destination for the drainage from the land situated on each bank. From the earliest times inland towns have always, when possible, been established upon the banks of a river or stream, in order to be within easy reach of an abundant supply of drinking water, and for the convenience of commerce. As the populations increased the amount of water used and fouled became greater and greater, owing to the soil becoming saturated with excremental matter due to the earth method of disposal which was in vogue for so many years.

SUBSOIL WATER OR GROUND WATER.

Subsoil water is that which has percolated the strata immediately below the soil, and is generally easily obtained by means of shallow wells. Subsoil water is one of the most frequent sources of supply, particularly in villages, but it is exceedingly liable to pollution, especially in the vicinity of houses, farms, &c. The amount of water which enters the soil depends upon the permeability, and varies with the nature of the strata, gravel soils being the most and clayey soils the least permeable. The quality of subsoil water also varies with the nature of the subsoil and the proximity to houses. Subsoil water from the chalk, lias, oolite, and limestone districts will be hard, but that supplied from the older formations, such as the Yoredale and millstone grits, as also that from sands and gravels generally, will be soft if uncontaminated. Water collected by means of shallow wells in the proximity to human habitations is often most dangerous to health, owing to its receiving the leakage and soakage from privies, drains, and cesspools, although, notwithstanding the presence of these dangerous polluting matters, it is normally bright and palatable.

DEEP OR ARTESIAN WELL WATER.

Deep borings, or artesian wells, particularly those which pass through impervious into pervious water-bearing strata, are very important sources of water from the hygienic point of view, since many of these wells provide practically unlimited amounts of water of almost absolute organic purity. The geological conditions do not always, however, favour this type of well. The older rocks, such as the Devonian, millstone grit, magnesian limestone, and coal measures provide but little water by this means. The new red sandstone, oolites, chalk, lias, and greensands are the great water-bearing strata. These formations contain vast volumes of water stored up in their pores and fissures, and are

capable of providing practically unlimited supplies of drinking water of the highest purity, and it is a matter of surprise that greater use is not made of this source of supply. The Rivers Pollution Commissioners found the deep well waters from the chalk "almost invariably colourless, palatable, and brilliantly clear. The chalk formation constitutes magnificent underground reservoirs, in which vast volumes of water are not only rendered and kept pure, but stored and preserved at a uniform temperature of about 10 deg. Cent., so as to be cool and refreshing in summer, and far removed from the freezing point in winter."

SEA WATER.

Sea water is but of little importance from the hygienic point, but is of great interest chemically. Sea water taken from the surface of the ocean, ranges in specific gravity from 1022·0 to 1029·0, pure water being 1000·0, and contains from 3·3 to 3·9 per cent. of dissolved solids. The water of narrow seas may contain less than this, thus the Baltic only contains 1·8 per cent. of solids. The water of inland seas or lakes may, however, be heavily loaded with dissolved solids; for instance, the Dead Sea contains 24·0 per cent. of solids.

The solids of sea water consist in the main of common salt (sodium chloride). According to Dittmar, the solids of sea water on the average have the following composition:—

Chloride of sodium	77·7	per cent.
Chloride of magnesium ...	10·9	,, ,,
Sulphate of magnesium ...	4·7	,, ,,
Sulphate of calcium... ...	3·6	,, ,,
Sulphate of potassium ...	2·5	,, ,,
Bromide of magnesium ...	0·2	,, ,,
Carbonate of calcium ...	0·3	,, ,,

GENERAL OBSERVATIONS ON REFUSE DESTRUCTORS.

Duty per Cell.—The quantity of house refuse destroyed per cell per day varies from 3½ tons up to 10 tons, and in the Beaman and Deas' furnace from 20 to 24 tons per cell per day. Much depends, however, upon the care or the reverse in stoking, upon the class of material, and the frequency of removal of clinker; also upon the question as to whether the whole of the refuse passed into the furnace is thoroughly cremated.

Great attention is now being directed to the utilisation of the surplus heat derived from the combustion of refuse, and in many towns, such, for example, as Cambridge, Shoreditch, and Hereford, the main object aimed at is not the riddance of the largest quantity of refuse possible per cell, but the full utilisation of all the heat available from this class of fuel—provided the material is properly burnt and without trace of nuisance.

Amount of Residuum, and its Uses.—The amount of residuum, in the shape of clinker and fine ash, varies from 22 to 37 per cent. of the bulk dealt with. About 25 per cent. is a very usual amount.

The clinker is found to be useful for mortar making, is ground with lime in a pug mill, and, in some towns where there is a demand, is sold at a profit. It has also been applied to the manufacture of paving slabs, &c., and is a very useful material for bottoming roads carrying a light traffic. Where there is no demand, and where the above uses do not arise, it is found to be expensive and difficult to dispose of

At the Battersea destructor depôt, during the year from 25th March, 1896, to 25th March, 1897, it appears that 2060 tons of clinker were carted away by contractor, 1989 tons given away at the works, and 1653 tons were used by the Vestry. A considerable amount of the residue is utilised in the manufacture of tar and concrete paving, a large quantity of which has been used in paving the footpaths of new streets and other paths in the parish, or sold to contractors and adjoining parishes. During the same year the removal of old tins and fine ash entailed an expenditure of £127 2s. 4d., whilst the cash received for clinker was £24 3s. 1d.

Of the total residue arising from the working of an ordinary refuse destructor it is found 8 per cent. to 9 per cent. consists of "*fine ash*," and 17 per cent. to 18 per cent. of "*clinker*." These amounts vary somewhat in almost every town, and depend upon:—

(*a*) The habits of the people, and the method and frequency of dust collection.
(*b*) The time of the year, and the state of the weather.
(*c*) The quantity of "trade refuse" dealt with.
(*d*) The locality of the town, and the amount of coal used in domestic fires.
(*e*) The proportion of vegetable refuse.
(*f*) The temperature of the furnaces, or whether forced draught is in use.

As this residuum amounts to from one-fourth to one-third of the total bulk of the refuse dealt with it is a question of the utmost importance that some profitable, or at least inexpensive, means should be devised for its regular disposal. The following are among the many uses to which it has been put:—

(*a*) Forming bottoming for macadamised roads.
(*b*) Crushing to suitable size, and mixing with Portland cement for making concrete, which may be applied to any of the uses to which concrete is usually applied.
(*c*) Crushing to small size, mixing with cement for making paving slabs.
(*d*) Breaking and sifting and mixing with fine ash for use upon suburban footpaths, or cinder footwalks.
(*e*) The fine ash may be used as a cushion bed for paving sets.
(*f*) Mixing clinker with lime, placing in a pug mill with water for the manufacture of mortar. This is a very general, and in many places profitable, mode of disposal.
(*g*) The fine ash has been suggested as a suitable base for the manufacture of carbolic powder.

(*h*) In some cases, for want of a better mode of disposal, it is used for filling in old quarries, gravel holes, pits, or other depressions in the suburbs of the town.

(*i*) There are also instances where it has to be barged away or sent to sea in steam hopper barges, and discharged in deep water. This is done at Liverpool, the cost of disposal being 2s. per ton.

(*j*) The ashes have been used for mixing with heavy clay soil on sewage farms.

(*k*) It has also been suggested that the ashes would improve the quality of ordinary bricks if mixed with brick-earth and clay.

Manufacture of Flagging for Footpaths.—In the manufacture of flagging for footpaths the clinker may be broken to suitable sizes, and made into Portland cement concrete, and laid *in situ* upon the footwalk about 3in. or 4in. in thickness, and trowelled up to a face. In order to prevent upheaval and cracking, the disastrous effects of which may oftentimes be observed in monolithic concrete footpaths of large unbroken area, the concrete should be laid in alternate lays of not more than 6ft. in width.

Paving Slabs.—Sometimes the clinker concrete, made in the ordinary manner, is placed in iron-lined moulds of suitable dimensions, and rammed by hand punners into the moulds. When the concrete is sufficiently set, the sides of the mould are removed, and the slabs stacked until they are sufficiently hard to lay upon the paths. This is usually from six to nine months after manufacture. The appearance of the flag is somewhat against it, but in Liverpool this has been improved by painting the surface with a fairly strong mixture of Portland cement and water, which has had the effect of brightening the surface and of filling in the interstices in the flags. In Southampton and elsewhere the crockery is taken from the refuse, smashed up, and used for facing the slabs, which, by a slight stretch of courtesy, is considered by some to give them a pleasing mosaic appearance. In speaking upon the durability of this class of slab, Mr. J. Price (Birmingham) has given it as his experience that after twelve years there has not been more than about $\frac{1}{8}$in. wear on flagging in crowded thoroughfares.

Mr. H. Percy Boulnois, M. Inst. C.E., when city engineer of Liverpool, introduced a method of making clinker concrete flags under hydraulic pressure, and has given the following description of the process of manufacture:—[154]

"The plant, which has been patented by Messrs. Musker, of Liverpool, consists of a hydraulic press or 'ram,' the pressure for which is obtained from the Liverpool Hydraulic Power Company, who give a pressure in their mains of 750 lb. on the square inch, which is used for the moving operations; but for the final pressure an 'intensifier' has been introduced between the main and the press, which raises this pressure so that the final pressing operations reach a pressure of 2¼ tons on the square inch. The clinker is broken in a small crusher worked by the engine supplied with steam by the destructor, to about $\frac{3}{8}$in. size, and this is mixed by hand on an ordinary bunker in the proportion of one part of cement to three parts of broken clinker, the compo being mixed very wet.

"The frame in which the mould is placed works in a horizontal direction, upon the rails supporting the frame, by hydraulic pressure, and the mould is filled with the compo when it is outside the press, a pad being placed at the bottom of the mould, composed of a perforated zinc plate covered with thick insertions. When the man (who is filling) has screeded off the top of the mould, he places a felt pad over the mould, pulls a lever, and the frame passes into and under the head of the press. By means of another lever he raises the mould and frame right under the fixed head of the press, and by a third movement he brings the whole pressure from the ram directly upon the slab.

"This pressure is allowed to continue for about a minute, when water from the compo ceases to flow, and it may be observed that owing to the pads no cement comes out with this water. The pressure is then relieved, the frame is allowed to drop, and then withdrawn by hydraulic pressure outside the press.

"Underneath, and level with the ground, a movable platform is provided, which is worked vertically by hydraulic pressure. Upon this platform a small trolley is run, having had previously placed upon it a movable flat board provided with handles, and upon this board the slab is received. In the meantime the frame containing the mould and slab is turned over and the platform lifted, which brings the flat board already referred to close up under the slab, and by turning a handle the nuts pressing against the heavy false bottom, or die at the bottom of the mould are slackened, which then falls and pushes out the slab in the mould; and consequently, when the platform is lowered the slab comes out with it, and is wheeled off on the trolley, and carried on the flat board in question by two men to a suitable position, where the slab is allowed to ripen for a couple of days, and is then up-ended.

"The number of men employed is as follows A lad works the lever handles, fills in and screens the compo in the mould, and three men manufacture the concrete and pack the slabs. About 45 yards of slabs are manufactured per diem, the cost being as follows:—

Cost of manufacture of one yard of clinker concrete flagging 2½in. thick.

Material.	Cost.
*65 lb. of Portland cement	10¾d.
†152 lb. of clinker	nil.
‡Water	¼d.
Labour	5½d.
Plant, contingencies, and supervision ...	3¾d.
Total cost per yard... ...	1s. 7¾d.

* Varies with cost of cement. † Really a saving of 1¾d.
‡ This item could be dispensed with where pressure is obtained by using steam-power of destructor.

"The total cost of manufacture is thus about 1s. 7¾d. per square yard, without reckoning the saving in using the clinkers. The sizes of the slabs that are made are 2ft. by 2ft., 2½ft. by 2ft., and 3ft. by 2ft., each being 2½in. in thickness.

"Some of these slabs have been laid twelve months and show no sign of wear, but sufficient time has not yet elapsed to say whether they will last as long as Yorkshire or other natural stones; but from the experience already gained it would appear that this class of flag will have a life as

[154] "The Disposal or Utilisation of the Residue from Towns' Refuse Destructors." (June, 1896.)

long, if not longer, than Yorkshire flags, and owing to the porous material with which they are made, the clinker-paving slabs have a foothold much better than the natural stones. Their colour is rather dark, but this slight objection may be obviated by painting the flags, after they have been laid, with a mixture of cement and water, which takes some time to wear off.

Tests of machine-made clinker concrete flags, 2½in. in thickness.

Age of flag. Months.	Breaking load applied at centre of flag. lb.
4	1804
4	1474
4	1742
4	1917
4	1608
4	1752
6	2061
6	1966
4	1859
4	1659
4	1589

"The above table gives some tests of these slabs which have been made, and when the youthful age of the slabs is taken into account, they may be considered very satisfactory.

"The total cost of the machinery as supplied and fixed by Messrs. Musker was £1275, the foundations and necessary plant cost £225, exclusive of the clinker crusher, which cost £45, making a total for the whole installation of £1545."

In connection with the above process the Adamant Stone Co., Ltd., in 1896, brought an action against the Liverpool Corporation for an alleged infringement of their patents of 1884 and 1893. The 1884 patent appears to have been for making slabs out of Parian, Keen's, or other cements in a porous mould under pressure; and that of 1893 for using for a similar purpose clinker broken to the size of small shot. The claim for the 1893 patent was dismissed with costs, but in regard to the 1884 patent it was held that the claim was good, and that it had been infringed, and, consequently, on this count judgment was given for the plaintiffs, with costs. Commenting upon this case, the *Surveyor* (December 11th, 1896) says:—"The effect of the judgment appears to us to be that municipal engineers need be under no apprehension that the mixing with cement of clinker (even when the latter is broken to the size of small shot), and the subsequent subjecting of the mixture to pressure, is an infringement of any existing patent. But—and the limitation is one it would be as well to note carefully—if this pressure is effected in a *porous* mould the process is an infringement of the 1884 patent of the Adamant Stone Company. Moreover, it is also worth noting that, in the ordinary course, the company's patent can only run for two more years."

The defendants appealed, but ultimately it was ordered to stand over until the adjournment, with a view to a settlement. The appeal was then withdrawn, in accordance with an arrangement between the parties, the terms of which did not transpire.[155]

In regard to the utilisation of the residue from destructors, Mr. N. Blair, M. Inst. C.E., of St. Pancras, said, at a meeting of municipal engineers at Brighton (June, 1896), as his Vestry had to pay for the removal of this residue, he had endeavoured to find other methods of treating fine ash and clinker, and to show whether it would compare favourably with other material he made briquettes of cement composition, using in some of the most suitable clean sand, and compared them with cement briquettes made of fine ash or of crushed clinker. One might naturally expect to find that the selected sand would give better results than the briquettes made of this composition from the fine ash, and he was surprised to find that it was otherwise. The result upon briquettes of 1 square inch section, in which the proportion was 3 to 1 of fine ash and cement, at three months was 204 lb. breaking strain, and in the case of the briquette made of the best sand obtainable for the purpose, 179·5 lb. The ordinary Thames sand, which is very largely used in London, dropped down to about 46 lb.; so that the cement composition made of the fine ash of the destructor furnace proved better than that made from the best sand obtainable. It was the same with concrete. He had some concrete blocks made for testing purposes. The first lot of blocks—12in. cubes—were mixed 5 to 1. The blocks made of clinker taken from the furnace mouth, containing tins and all classes of fine material, mixed in the proportion of 5 to 1 with cement, broke at the age of three months under a crushing weight of 55·6 tons. Rough Thames ballast containing stone from 2in. diameter down to sand, mixed in the same proportions and at the same age, broke at 45·2 tons, and fine Thames ballast containing pebbles from ¾in. down to sand broke at 23·7 tons, so that in this case also the concrete made of clinker, just as it came from the furnace mouth—not selected, not even riddled—gave the best results.

Mr. Blair has also attempted to convert the fine dust into carbolic powder. A sample was examined by a firm of manufacturers, who reported that they thought it was very suitable, and offered to make carbolic powder from the dust, employing the same proportion of acid as in the ordinary 15 per cent. powder. This they could sell at 25s. per ton less than the ordinary powder of commerce.

Mr. J. H. Cox, M. Inst. C.E., of Bradford, has had destructor flue dust analysed, and found there was very little nitrogenous matter in it—in fact, it was not worth naming as to its value for manurial purposes. It was only ·023 per cent., but the analyst said it might be useful to manure manufacturers for some of their preparations which require an absorbent.

At one depôt in Bradford there are twelve cells, burning 24,000 loads in a year, producing approximately 6000 loads of clinker, 2000 loads of which are made into mortar. Being in a flag-stone district, the question of providing machinery for slab making has not been fully gone into; but a good outlet for the material has been found in putting up crushing and screening machinery. The clinker is crushed and screened into various sizes, and is proposed to be used for making common asphalt by mixing with pitch and tar, and using on the suburban foot-walks.[156]

[155] The *Surveyor*, March 12th, 1897.

THE SANITATION OF DOMESTIC BUILDINGS.

By Frank Latham, C.E., M. San. Inst., &c., Assistant Surveyor, Borough of Margate.

(*Concluded from page* 478.)

CHAPTER VII.

Section 2.

DRAIN CLEANSING.

Having in the foregoing articles given a general description of the work appertaining to house drainage, a few details with regard to their maintenance in a clean and sanitary condition will perhaps be useful. Although this operation seems an easy matter, especially where the drains have been carefully executed, yet in very few cases do the drains, when once carried out, receive that amount of attention at the hands of occupiers as is requisite for their maintenance in a cleanly condition. It is further an astonishing fact, that in hotels and factories it is far from an uncommon occurrence to find the drain literally choked with foreign substances, particularly so in the former. The writer has had instances where complaints have been made of drain stoppage, and which upon investigation have been found choked full of pea pods and other such articles, which had been thoughtlessly disposed out of sight down the nearest inspection chamber. It is also a frequent occurrence to find the drains of hotels blocked with fat, especially where the cook has no personal interest in saving such matters.

There is again the frequently complained of gully trap, which is used year after year without attention, till a nuisance is created, and the Sanitary Inspector is summoned to search for the offender, and finds perhaps the gullies choked with filth, and of little or no use as a seal against the escape of drain air. A neglected grease trap is also a constant source of nuisance, and will sometimes throw off most disgusting odours.

The sink waste syphon sometimes becomes stopped, and this instead of being gently cleared by removing the thumb screw provided for that purpose, is more often ineffectually forced by some inexperienced person. The water-closet and such appliances require occasional attention, to remove the incrustation that forms in the trap, &c., otherwise a fetid odour will be inseparable to them. Cisterns used to hold water for drinking and domestic purposes require to be regularly emptied and cleansed, which rule also applies to rain-water tanks, especially as the latter are often situate under ground and sometimes under the floor. The writer only recently investigated the case of an old tank, wherein, amongst other things, three rats were found; in another instance several dead birds were found in a cistern in the roof.

Ventilation pipes should be periodically examined, and any rust or scaling that might have lodged at the bend, or birds' nests, removed. There are also occasional articles, such as nail and tooth brushes, combs, pumice stone, and like obstructions, which gain access to the drains, and become lodged in the traps, &c., and if not removed will soon cause trouble. The insufficient flushing of drains, resulting from cisterns being out of order, is likely to cause them to become choked, and also to event in a dangerous nuisance, which cannot be too carefully guarded against.

As was explained in Chapter V., one of the principal aims in construction of house drains should be to give inspection facilities to the whole system, so that, in the event of obstruction, ready access could be given for the speedy detection and removal of the cause, without disturbing or damaging the soundness of the work.

Numerous appliances are used for clearing and cleansing purposes, the principal of these articles being as follows:—Drains cannot be effectually unstopped and cleansed without the aid of clearing

Fig. 97.

rods, a set of which should be in possession of every large establishment. They consist of short malacca canes, and are jointed together for use by means of brass male and female screw connections. They are usually 3ft. in length, and are strapped together in convenient bundles of from ten to thirty-three rods. There are a number of fittings used with these drain rods for various purposes; one of the most useful being the double-worm screw and guide wheel (Fig. 97). By its use such obstructive articles as rags, dishcloths, and paper can be removed. The double-spiral screw is particularly handy in unstopping intercepting traps from the air shaft. Some other useful accessories are the jointed scraper, which is employed for raking purposes. The spring hook which, being chisel shape, is for breaking through accumulations of solid obstructions in drains. The

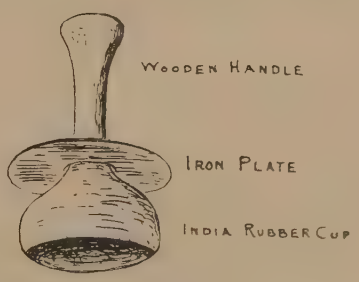

Fig. 98.

rubber plunger is for forcing choked drains, but this work needs to be carefully done, as there is a danger of pressing the obstruction tighter into the drain. The brass guide wheel is used to conduct the rods round corners, and the whalebone or bass brush with guide wheel is used for sweeping and cleansing drains.

There are also several other articles for cleansing purposes; the closet brush is for removing any incrustation from the basin and trap; the gully ladle for removing filth from gully traps; and the sink force cup (Fig. 98) being amongst the most useful.

THE CUTTING-OFF POWERS OF WATER COMPANIES.

By Dr. T. ORME DUDFIELD, M.O.H., Kensington.

THE Public Health (London) Act, 1891, Sec. 49, gives effect to the recommendation made by me many years ago, that a metropolitan water company should be required to give information to the Sanitary Authority, when, from any cause, they had exercised their statutory right to cut off the water supply of an occupied dwelling-house. Every company is now required to give such notice within twenty-four hours after exercising the said right, under liability to a fine not exceeding £10 for default. The power to cut off the supply is, no doubt, of some value to the companies, for "an occupied house without a proper and sufficient supply of water," is "deemed unfit for human habitation" (Sec. 48). In all such cases reported by the several companies, the Sanitary Authority are obliged to take steps to ensure restoration of the supply—which is necessarily preceded by the payment of the company's claim. The cutting-off powers were materially limited in 1887, by the Water Companies (Regulation of Powers) Act, which is described as "an Act to limit the powers of the water companies to cut off the tenant's water supply when the rate is paid by the landlord," as is very generally the case in regard to tenement houses and houses otherwise occupied in lodgings, &c., by the poorer classes. The beneficent result of this legislation is, that the water supply of the poor is generally secured, and that without loss to the companies.

The time has come that the power to cut off the supply from an occupied house should cease; and that, as I suggested, in 1882, "the company should be left to their remedy for the recovery of the rate as a debt, like other traders," and not be allowed to create a dangerous nuisance merely as a coercive measure for securing the payment of the rate. One enlightened company, the East London, resolved some years ago to abandon the barbarous practice of cutting off; and, I am informed by the secretary, have had no cause to regret the decision. They sue the defaulter, and the result is stated to be, on the whole, "highly satisfactory." The New River Company also, I understand, summons largely in preference to cutting off, and other companies now, probably, are following suit. Defaulters are summoned in the Police-court; but the magistrates have no jurisdiction unless the company proceed within six months of the debt becoming due; and the debt, *i.e.*, the rate, is due in advance. Inasmuch, therefore, as the companies only collect half-yearly, they must proceed before the expiration of the six months, and hence have to sue before the second quarter has expired, which appears to be a hardship. If greater facilities were given to the companies for recovering this rate, probably they would be willing to waive their right to cut off the supply, or consent to its abolition. I do not suppose that a question of this sort comes within the limits of the inquiry now being made by the Royal Commission on Water Supply. It might, however, well be brought to their attention. From the public health point of view, it is one of great importance.

As already stated, a technical nuisance is created by cutting off the water supply. Actual nuisance also may result, of which a striking instance has recently occurred at Hooper's-court and Garden-row, Knightsbridge. This property, shortly to be demolished, comprises thirty-four little houses built many years ago on garden spaces at the rear of houses in Brompton-road, a few doors west of Sloane-street. Hooper's-court comprises twenty-six houses, Garden-row eight. On the 21st March, the weekly tenants living in Hooper's-court (No. 7 to 26) and Garden-row, received notice to quit the houses, of which many of them had been in occupa- for a considerable number of years. They are described to me as respectable people, who paid their rent, and found employment in the locality. The number of persons affected by the notices, estimating five to a house, would be about 140. Needless to say, great distress was caused by the requirement to leave, owing to the difficulty of finding new homes. Some of the people succeeded in doing this; others, in occupation of eleven houses, lingered on after the 28th, trying their best, as I am informed, to find lodgings within a convenient distance of their work.

Technically, of course, they were trespassers. In order to get them out, by making their homes unfit for human habitation, the Chelsea Waterworks Company were ordered to cut off the water supply, for which the landlord was liable under "Forrest Fulton's Act," the commonly known title of the "Water Companies (Regulation of Powers) Act, 1887." The order, given on 13th April, and executed on the 21st, gave rise to an abominable nuisance by the choking of the water-closets, the pans of which, at the present writing, are full and overflowing. This matter was brought to the attention of the Sanitary Committee on the 26th ult. The Committee directed the issue of two notices; one requiring the owner to lay on the water, and the other requiring him to unstop the choked water-closets, within two days. The Surveyor was instructed to have these closets unstopped, in the event of failure on the part of the owner, the cost of work to be charged to the owner, who, as owner, is liable for the abatement of the nuisance. Whether the owner can be made to restore the water supply is perhaps doubtful. Had the tenants been in legal possession, the Company could not have deprived the houses of water had the owner failed to pay the rate. Forrest Fulton's Act would have prevented this. Having regard to the circumstances above set out, I hoped that the Company would have turned on the water for the use of the people for the short time they are likely to remain in the houses; the cost to them of such an act of benevolence, not to say humanity, would have been infinitesimal and absolutely inappreciable.

SHEFFIELD.—Some alarm has existed at the West End on account of an outbreak of scarlet fever at Ranmoor. Twenty-four or twenty-five cases have been reported to the Medical Officer of Health, who has taken adequate steps to prevent the spread of the infection. All the cases are satisfactorily isolated. The Medical Officer has traced the origin of the fever, and there is no likelihood of a recurrence. Residents at Ranmoor and Broomhill may take it that the worst is now over, and that, though several households have been attacked, there has been nothing in the nature of an epidemic.

Food and Health

SUPPLEMENT TO

THE SANITARY RECORD.

No. 16. MAY, 1898.

FOODSTUFFS UNDER SCRUTINY.

WHAT TO EAT AND DRINK, AND WHAT TO AVOID.

"SANITARY RECORD" ANALYSES.

IMPORTANT ANNOUNCEMENT.

OWING to the growing popularity of this feature of our "Food and Health" Supplement, we have found it necessary to make arrangements whereby, in future, much fuller reports will be given of proprietary articles than have appeared hitherto. It has been our custom to solicit samples of articles for investigation from the manufacturers direct, unconditionally; but in future such samples as we receive from the proprietors thereof will require to be accompanied by a declaration that the sample is selected from stock, and not put up for the special purpose of analysis. Failing this we shall make the purchases ourselves, selecting the articles at random from the various retail establishments where they are sold.

We have retained the services of Mr. C. G. Moor, M.A., to examine and report on the various substances submitted to us.

All such analyses may of course be quoted as having appeared in THE SANITARY RECORD, but the date must be given, and Mr. Moor's name must not be quoted for advertising purposes without special permission.

"Sap" Brand Humanised Milk and Koumiss.

I HAVE duly examined the samples of Humanised Milk ("Sap" Brand) and Koumiss, prepared by the Milks Preparations Company, Brentwood.

Both of these preparations are thoroughly satisfactory in every way. The Humanised Milk, as will be seen from the figures below, is as exact a copy of healthy human milk as can possibly be prepared. Comparing the composition with the average constitution of a large number of the most trustworthy records of analyses of human milk by Pfeiffer, Leeds, Meigs, Johannessen, and Rotch (page 9, "Milk and Milk Products," Pearmain and Moor), it will be noted that the "Sap" Brand is almost identical with the averages there given for fat and albuminoids, while a little low in milk-sugar.

The figures yielded by these two preparations are as follows:—

	Humanised Milk.	Koumiss.
Fat	3·50	1·40
Albuminoids	1·36	1·33
Ash	·48	·53
Milk-sugar	4·81	2·91
Proof spirit	—	1·00
Water	89·85	92·83
	100·0	100·0

The Koumiss is well prepared, of pleasant flavour, and satisfactory as regards its composition.

FOOD ADULTERATION FRAUDS IN FRANCE.

M. DE NANSOUTY has recently been withdrawing the veil which conceals the composition of coffee in France. He tells us that even the careful man who buys his coffee in the green berry is not altogether safe; very inferior berries are dyed to match the better sorts, or some of the berries are made of clay moulded and dyed to look like the genuine berries with which they are mixed. If he buys his berries roasted he is more easily deceived. The artificial berries in this case are made of coffee grounds mixed with baked flour. The berries, false and true, are then roasted with a little fat, white of egg, sugar, or molasses, and acquire a beautiful brown varnish "pleasing to the eye."

The weight of both green and roasted berries is increased by exposing them to steam so that they imbibe moisture. But the man who buys his "coffee" ground is indeed rash. The list of constituent parts is long: chicory (which itself is sometimes adulterated!) beetroot, turnips, parsnips, carrots, dandelion, acorns, horse-chestnuts, hazel nuts, figs, prunes, couch-grass, pistachios, almonds, walnuts, pea-nuts, dates, apples, pears—all these substances, generally in "damaged" condition, are mixed together, ground and roasted, and mixed with a little real coffee. In a recent instance ground stone was found to have been added, but this was considered to be carrying business enterprise too far even for a Belgian, and the parties are thought likely to be punished. Some manufacturers add the sweepings of the warehouse, so that the powder which is then put up in tins and labelled *café de luxe* must have a fine confused flavour.

As to the milk, a certain improvement has taken place in many continental cities. The Dutch

official analyst, for instance, when he began his examinations in Rotterdam in 1893, found that 70 per cent. of the milks he tested had been tampered with; the percentage had fallen in 1897 to 3·3. In Brussels lately a batch of twenty milk sellers were summoned and fined. One man admitted that his milk had been "baptised," but he argued that it was good enough for *les Bruxellois*. A woman had put a notice that her milk was skimmed, on the handles of her jugs. What more reasonable for a milk seller than to hold a jug by its handle? If the buyer did not then see the announcement on the handle, what of that? the ingenious lady argued—it was there.

Finally, and not to prolong unduly this list, it may be said that the mayor of a small commune in France is now "wanted" on a charge of mixing plaster of Paris with his flour. He did not deny the fact, but said that he merely sold the flour, and had no idea that anybody would be so indiscrete as to use it as food. When, however, it was proved that most of his customers were bakers, or bakers' brokers, the mayor thought it well to leave home in order to "collect some debts." Butter is, of course, largely adulterated in Belgium. At Liége nearly one-fourth of the samples taken contained margarine in proportions varying from 30 per cent. to 75 per cent. Bearing in mind the easy-going way in which we admit milk, butter, and other food products into this country, it is worth while to call attention to these official records of the extent to which the practice of adulteration prevails in neighbouring countries ambitious to supply our markets.

DANGER IN EXCLUSIVE MEAT DIET.

Modern Medicine contains a short paper on the above subject, from which we extract the following:—It is apparent that in a case of a person subsisting upon a flesh diet, two evils result:—

(1) An increased rapidity of disassimilation, whereby tissue wasting occurs at too rapid a rate.

(2) A saturation of the system with tissue poisons.

When the urine contains three to four times the normal amount of urea, and other toxic poisons in like proportions, it is an indication that the whole body is, to a similar extent, saturated with these poisonous substances.

Another item of interest in the table of Lotz is the fact that the alkaline sulphates, which are products of intestinal decomposition, were entirely absent under a non-nitrogenous diet. Under a mixed diet the amount was found to be seven grammes, and under a nitrogenous diet ten grammes.

From these facts it must be apparent that nothing can be more dangerous in cases of Bright's disease, and in all cases of renal insufficiency, than a flesh diet, and that the greatest safety for the patient is to be found under a diet from which flesh food is excluded. It is also easy to understand why a flesh diet is particularly dangerous in diabetes. In this disease, in which there is naturally a tendency to waste, and to toxæmia through a failure of the kidneys to maintain a condition of requisite tissue purity, the employment of a meat diet not only increases wasting, but also greatly increases the tendency to general poisoning from the accumulation of excrementitious elements.

HOW THE SALIVA ASSISTS THE DIGESTION OF FOOD.

Even the merest tyro in physiology is familiar with the fact that the saliva not only prepares the food so that it can be readily swallowed and acted upon by the gastric and intestinal juices, but that it contains a ferment which possesses to a high degree the ability of commencing and even carrying to completion the transformation of starch into sugar, or, in other words, the preparation of carbohydrate materials, so that they can be readily absorbed and appropriated to the various uses of the economy.

For many years when patients came to a physician complaining of symptoms of indigestion it was the custom to administer pepsin and hydrochloric acid under the erroneous idea that it was the proteids in the food which were not properly treated by the digestive juices, and that relief could be obtained by aiding the stomach in the manner indicated.

Only comparatively recently has the importance of pancreatin digestion been recognised as surpassing that carried out by the gastric juice, and still more recently has the profession come to realise the fact that in many cases the predigestion of starchy foods, or the administration of diastatic ferments capable of aiding in their digestion, is in a certain proportion of cases far more important than the administration of pepsin or pancreatin for their proteolytic action.

Recent studies which have been made in the laboratories of Yale University emphasise the value of the saliva as a digestive juice. They were carried out by Professor Chittenden, who reported his results at the last meeting of the American Physiological Society in Ithaca. This investigator showed that great variations in the amyolytic power of the human saliva take place. Thus, he found that saliva collected before breakfast is stronger in amyolytic power than that secreted after breakfast. He also found that this greater power before a meal is not due to any increase in alkalinity, but to the greater concentration of secretion coming from glands that have been resting. He also discovered that stimulation of the mucous membrane of the mouth by the vapour of ether or chloroform, or by any other substance which irritates that mucous membrane, causes a secretion richer in digestive powers and solid matters than that caused by mere mechanical stimulation.

Professor Chittenden's experiments indicate the fact that those persons with deficient digestion of the starchy articles of food should avoid chewing any such substances for a considerable period of time prior to a meal, as by this means the salivary glands will have an opportunity to rest and the liquid which they pour out when starch is taken will then be competent to digest its share of the meal. Where tobacco, for instance, is placed in the mouth and kept there until the time of the meal the salivary glands are not only unable to secrete enough amyolytic ferment to aid in the digestion of the starch, but are also unable to

secrete enough fluid to thoroughly soften and disintegrate the food, and as a result the indigestion of all articles of food ensues, since the pabulum when swallowed is not in a fit condition for gastric or duodenal digestion.

INTERESTING FACTS ABOUT CHEESE.

The manufacture of the richer and more expensive brands of cheese, which is carried on for the most part in Europe, is an exceedingly interesting process, requiring an immense amount of skill and patience. The knack, or art, of making certain kinds of cheese has never been successfully imitated, and the natives of certain parts of the Continent of Europe, therefore, still retain a sort of monopoly of the trade. The modern cheese manufacturers, with all their scientific methods and apparatus, have failed where these simple peasants have succeeded. It is not generally known that the familiar Roquefort cheese comes from a town of the same name in the south-western part of France.

The cheese is made from cow's milk, and the curious little green particles are merely the crumpled coarse bread of the peasants, which is thrown into the cheese. The cheese is first made by the peasants throughout that part of the country and then carried to cellars regularly prepared for it, where it is stored to give it its peculiar flavour. These cellars are hewn out of the solid rock along the sides of the hills, and it is thought that some peculiar property of the stone or the dampness serves to give the characteristic flavour to the cheese. These cellars are constructed at considerable expense, and are owned by syndicates, who construct them and charge the peasants for storing the cheese there, or they buy the cheese outright and cure it themselves. This picturesque little section has an undisputed monopoly of the trade.

The Brie cheese also comes from a town whose name it bears. It lies to the north of Paris, and regularly exports immense quantities of cheese. This cheese is also made of cow's milk. It has been successfully imitated in other countries, notably in America. At the present time there is, as a matter of fact, very little of it imported from France. Limburger cheese, which was once manufactured exclusively abroad, is also produced in America so successfully that the importation of it has been entirely stopped.

The most expensive cheese manufactured is the truffle cheese, which is imported from France. This cheese, as its name suggests, is made of truffles, and is worth about a dollar a pound in France. The familiar Edam cheese, which is made in Holland, is also imported in considerable quantities. The sago cheese, which is made from the milk of goats, is manufactured in Switzerland by the peasants, and imported in large quantities. The cheeses bearing English names, which find a large sale in America, are made for the most part in that country. The farmers in New York State have become so expert in manufacturing many of these brands that this American cheese is now being exported to England, and is sold in competition with the original English cheeses.

BEVERAGES: BENEFICIAL AND OTHERWISE.

Water is a most important article of diet. It forms 60 per cent. to 70 per cent. of the body. In milk, which we have taken as a type of a perfect food, there is 80 per cent. of water. It is essential that water should be pure and free from all contamination. Many diseases, such as cholera and typhoid fever, are frequently introduced into the system by water.

If the purity of water is suspected it should be boiled before being drunk. The insipid taste of boiled water, which depends on the air suspended in it being driven off by boiling, can be removed by pouring it into a bottle till it is three parts full, and then shaking it well. This restores the air which has been driven off. Filtering by the ordinary filters is of no use in getting rid of germs, which are the most important contamination of water. Hard water may produce some kinds of disease, but boiling will make it softer.

A sufficient quantity of water is necessary to supply the tissues of the body, and to flush out the secretions from different organs. If too little fluid is taken it may lead to disease. A tumblerful or two of hot water at bedtime is very useful in washing away the *débris* of digestion, and preparing the stomach for more efficient work on the following day. Sipping hot water slowly gives warmth to the body, and acts as a stimulant by quickening the pulse. Drinking too much fluid during meals tends to retard digestion by diluting the gastric juice.

The other beverages most frequently used are tea, coffee, and cocoa. It is a curious fact that Nature has taught man in different parts of the world to use these beverages, each of which is found to contain an active principle having nearly the same composition. They act as stimulants, causing exhilaration, exciting the brain, producing wakefulness, and relieving the sense of fatigue. When partaken of moderately they are most useful, but when indulged in too freely may produce some untoward symptoms.

Tea and coffee affect different people in various ways, and the same individual may be differently influenced according to the condition he may be in at the time. Tea may delay the digestion of certain substances, when taken with it, such as butcher meat.

The over-infusion of tea is injurious, not on account of the tannin, as is usually supposed, but on account of other deleterious products. Inferior teas are infused more quickly than teas of good quality. Tea should never be boiled.

Alcoholic drinks are not necessary in health, because the highest health, mental and bodily, can be attained without their use. Thousands of our soldiers and sailors are doing all the hard work and enduring the fatigue of campaigns without partaking of them. It has been proved that all conditions of climate, even the extremes of heat and cold, can be well borne without alcohol in any form.

Alcohol is not a true food in the sense that it does not supply to the body any material required for building it up. The best that can be said for it in this connection is that by diminishing the oxidation of the tissues it lessens the necessity for food,

CONDENSED MILK: ITS COMPOSITION AND VALUATION.

Specially contributed by C. G. Moor, author of "Milk and Milk Products."

This article of food has at the present time come so universally into favour, both for every-day use on account of its convenience, and for the feeding of children, that it is well that attention should be drawn to the true composition of the many brands, some sixty in number, that are now on sale in this country.

So far as I have been able to learn, condensed milk seems to have been first used to any appreciable extent about forty to forty-five years ago, when it was bought more out of curiosity than anything else. Since then the trade has rapidly increased, till now it is one of the highest importance.

There are now three kinds of condensed milk sold in this country:—(1) Unsweetened condensed milk, (2) sweetened condensed milk, (3) sweetened skimmed condensed milk.

The first of these alone has really the right to the title condensed milk, though this term has by general consent been applied to the ordinary condensed milks which contain a large addition of cane sugar. Macfarlane, the Chief Analyst to the Canadian Government, in "Bulletin, 54, 1897," says that milk which has been condensed with the addition of sugar should bear the label, "Condensed Milk Mixture," or "Sweetened Condensed Milk." Of the first class, namely, the unsweetened milks, we have now several brands in this country, all of which are well prepared from milk containing its full proportion of cream, and without any preservative.

The following figures were obtained by me on some of these milks in 1895, and published in the *Analyst* for December. Since then I have examined them on several occasions, and have found their composition to be very constant, while they were always perfectly sound and well preserved:—

First Swiss Brand.

Fat	10·5
Milk-sugar	14·2
Proteids	9·7
Total solids	36·7

Ideal Milk.

Fat	12·4
Milk-sugar	16·0
Proteids	8·3
Total solids	38·0

Hollandia.

Fat	9·8
Milk-sugar	18·5
Proteids	11·3
Total solids	43·0

Viking.

Fat	10·0
Milk-sugar	13·2
Proteids	9·0
Total solids	34·2

In the case of this latter milk I have examined it regularly every year, and find its composition very constant and somewhat richer in fat than in the above analysis.

If we study the above figures we shall see that all these four milks are prepared by evaporating cow's milk of good quality down to one-third, consequently to prepare ordinary milk from them they will require the addition of two parts of water to one part of milk by weight.

The second class, or the sweetened condensed milks, is the most important, and the three best-known brands are probably the Anglo-Swiss, Nestlé's, and the Milkmaid, on which the following figures were obtained:—

Anglo-Swiss.

Fat	10·8
Milk-sugar	16·0
Proteids	8·8
Cane-sugar	37·1
Total solids	74·4

Nestlé's.

Fat	13·7
Milk-sugar	15·0
Proteids	9·7
Cane-sugar	37·2
Total solids	77·2

Milkmaid.

Fat	11·0
Milk-sugar	14·6
Proteids	9·7
Cane-sugar	38·7
Total solids	76·3

Nestlé's condensed milk appears to enjoy the distinction of possessing the largest amount of fat of all condensed milks.

In addition to the above mentioned there are twelve or fifteen other brands of condensed milk containing a proper proportion of fat, namely, not far below 10 per cent. by weight.

Some few years ago another class of milks was common, which were sold as "partly-skimmed milks," and contained varying amounts of fat, generally very little. This class has almost disappeared, and it is just as well that this is so, for it is simply an attempt to induce people to purchase a skimmed condensed milk on the idea that a part of the fat has been left in—what proportion, is left to the imagination. In January, 1897, I examined two condensed milks stated to be partly skimmed, and found practically no fat in either.

The law relating to the sale of condensed milk (and other foods) provides that the label must disclose the true nature of the package, and hence a tin of skimmed condensed milk must bear the word skimmed or separated on it. In many cases this is printed in microscopic letters which would never be noticed by the ordinary purchaser.

Time after time attention has been drawn to the fact that a skimmed condensed milk is not a suitable food for infants, as its constituents vary very greatly from the composition of human milk, and a moment's calculation will suffice to demonstrate this.

A young child with a healthy mother gets some 30 ounces of human milk in the 24 hours, which contains 12·3 per cent. of total solids, that is 4·1 ounces, in a day and night; this is made up of a little over 2 ounces of milk-sugar, rather more than 1 ounce of fat, and less than an ounce of proteids.

Now the composition of skimmed condensed milk

being as follows (an average from a number of skimmed condensed milks) :—

Fat	1·0
Milk-sugar...	15·0
Proteids	10·0
Cane-sugar...	40·0

It is obvious that nothing short of adding cream can possibly enable us to make a food out of it similar in composition to human milk.

But apart from the unsuitable composition of skimmed condensed milks, the directions given on some labels as to the dilution are calculated to kill children, and undoubtedly do so.

A. McGill, in the Canadian bulletin above mentioned, has found just the same thing in Canada. He says, "I have before me a brand of milk from which practically the whole of the cream has been removed, and which nevertheless instructs the purchaser to 'add 4 to 5 parts of water,' adding, 'if less water be added, it may be used instead of cream.' The same label instructs the purchaser to add 14 parts of water for the feeding of infants. This, it is needless to say, would be to put the unfortunate infant on a starvation diet."

In the paper on condensed milk in which the figures before quoted appear (*Analyst*, December, 1895), in referring to the unsuitability of skimmed milks for children, I suggested that in addition to the disclosure at present required by law, it should also be made compulsory to add the words "skimmed milk is unfit for the nourishment of children."

This is clearly seen by considering the composition of the liquid that would be produced on diluting a skimmed milk according to the directions given with many of them. Thus, supposing 14 parts of water are directed to be added, we should get a liquid containing only 4·4 per cent. of total solids, or about one-third of the amount present in human milk, while over half of the nourishment thus given consists only of cane-sugar without any fat whatever!

Even in the case of many of the well-prepared sweetened condensed milks the directions as to dilution are far too enthusiastic, and would result in the production of a very weak liquid indeed, though by no means so bad as in the case of the skimmed condensed milks.

Taking it all round, however, it must be admitted that our condensed milks in this country are much better and greatly more uniform composition than those sold in America or Canada.

For instance, if one collects a number of analyses of any one of the better-known milks sold in this country it will be found that its composition will be very much more uniform than is the case abroad. It is a rare thing for the fat to vary more than 1 per cent., even over a period of years; whereas an inspection of the figures obtained by McGill and other official Canadian analysts shows very wide variations on the same brand even when the samples were all purchased about the same time. In America, too, Charles P. Worcester (Massachusetts), in the years 1892, '93, and '94, analysed a number of milks, many of which show very considerable variations in their composition, even of the same brand, while their general quality is decidedly poor, and for the most part contained a lower quantity of fat than they should have if prepared from whole milk.

Mr. Gill has found salicylic acid as a preservative in Canadian milks, but I do not think that preservatives are used to any extent in the milks sold in this country; boric acid at least is not, as I have never detected it, though a large number of samples were examined for it. There is no need to use any preservative in the manufacture of condensed milk, as if the tins are sound it will keep indefinitely. Preservatives, if used, should be acknowledged.

Adulteration, properly speaking, does not exist at present, except in so far as passing off skimmed milk as condensed milk, though the giving of wilfully misleading directions for dilution ought to be an offence under the Food and Drugs Act.

I have been informed that in Germany condensed milk has been prepared, into which foreign fat (margarine) has been incorporated, and some enterprising persons in Glasgow have taken out a patent for the following enticing preparation (English Patent 2081, 1896) :—"Milk products, condensed, improvements in the manufacture of," W. F. Maclaren and A. Smith Fleming, of Glasgow.

"The object of this invention is to prepare a wholesome condensed milk from separated milk. Forty gallons of milk are mixed with 28 lb. of sugar and condensed to about 100 lb. To this is then added an emulsive compound consisting of 12 lb. of refined beef oil (oleo oil), 8 lb. of lime water, 1 lb. of corn flour, and 12 lb. of sugar. The emulsifying is preferably carried out in a steam-jacketed pan provided with an agitator, the lime water being gradually added during the mixing operation." This pleasing mixture could not be sold as condensed milk without the vendor being liable under the Food and Drugs Act, nor if it were sold in this country would he escape detection for long.

A similar attempt to add a fat to separated milk is mentioned in a Victoria newspaper (1895), in which a Mr. Munro exhibited a "condensed milk," prepared by adding to separated condensed milk a "compound," presumably an emulsified fat. The report states that the inventor did not claim that this preparation was fit for feeding children, in fact, he proposed to state that it was not suitable for this purpose on the labels.

The addition of any foreign fat would be easy of detection; all that is required is to extract the fat from about 50 grains of the sample by ether, having first mixed the condensed milk up with sufficient anhydrous copper sulphate to produce a powder that can be treated with ether or gasolene in a Soxhlet. The fat so obtained, after being warmed till quite free from the solvent, can then be examined by the Valenta test, and will, if true butter fat, form a clear solution with an equal volume of glacial acetic acid at a temperature below 40 deg. Cent., while foreign fats under similar circumstances remain turbid, and do not become clear till a temperature of 70 deg. or 80 deg. Cent. is reached.

THE cost of feeding the American army and navy is estimated to be nearly 1,000,000 dols. per day. If the conflict is prolonged to the end of the year, and the U.S. army invades Cuba, this sum will be more than doubled. Add to this the loss through so large a body being non-productive, and some idea is gained of the awful costliness of war.

SANOSE: A NEW DIETETIC.

This preparation appears to fill a place which has long been unoccupied as a means of administering nitrogen in an easily assimilable form to persons who cannot tolerate meat, or cannot be allowed foods containing sugar. It consists of a mixture of albumose and the casein of milk, and forms a fine white powder, which is quite free from taste, and forms a very perfect emulsion with water. It is hardly necessary to state that mere chemical analysis alone cannot give us adequate information as to the dietetic value of such a substance as this without such confirmatory evidence as is afforded by feeding experiments. Chemically examined, our analyst tells us that it contains *over* 80 *per cent.* of nitrogenous matter, which fully bears out the statements as to its preparation. What little ash remains on ignition consists of phosphates of calcium and potassium.

This preparation has been tested in actual practice by German medical men of the highest reputation, and their published results leave no doubt as to its value.

The application to which this preparation appears most particularly suitable is its administration with milk, the nutrient value of which may be greatly enhanced by its admixture. We may safely prophesy a wide field of usefulness for this unique and valuable preparation.

Sanose is prepared by Messrs. E. Schering, of Berlin, and obtainable from Zimmerman, 9, St. Mary-at-Hill, London, E.C.

DAIRYMEN AND THEIR SERVANTS.

IMPORTANT DECISION.

The case of "Roper *v.* Knott," which was recently decided by eight judges in the Court for Crown Cases Reserved, and remitted to Mr. d'Eyncourt at North London for conviction, came before the Court on Saturday, the defendant, Charles Knott, surrendering to be dealt with.

Mr. Walter Windsor appeared for the prosecution.

Mr. Roper, a dairyman in a large way of business at South Hornsey and Stoke Newington, said that on January 11th last the prisoner was detected watering his master's milk. He was charged with wilful damage; but ultimately the magistrate, acting on the authority of the case of "Hall *v.* Richardson," dismissed the prosecution, holding that no wilful damage in law had been committed. That finding was indeed the only finding that the magistrate could arrive at while the case of "Hall *v.* Richardson" remained as the governing case. The Divisional Court took the same view; but Mr. Roper, not being satisfied with the existing state of the law, which gave the milk carrier so much opportunity of defrauding his master, carried the appeal to the Court for Crown Cases Reserved, where eight judges decided that wilful damage had been committed, and the case was ordered to be remitted to the magistrate for conviction.

Mr. d'Eyncourt said that he had dismissed the charge against the accused not because he believed the man innocent, but because of the state of the law which was brought about by the decision in the case of "Hall *v.* Richardson." He fined defendant £4, 10s. 8d. the damage, or a month's hard labour.

FOOD AND FINANCE.

DR. TIBBLES' VI-COCOA (1898), LIMITED.

The statutory meeting of the shareholders of the above company was recently held at the registered office, 60, 61, and 62, Bunhill-row, E.C., Mr. Alderman Treloar presiding.

The Chairman, in the course of a lengthy address, referred to the present satisfactory position of the company, paying a glowing tribute to Messrs. S. T. and C. H. Williamson, and to Mr. Smith and Mr. Osborne, the four gentlemen who had brought the enterprise to its present unique position—a position which, he ventured to say, was without parallel. The causes which contributed to the great increase of business were reviewed, and were classed by the speaker as due (1) to the intrinsic merits of Vi-Cocoa, and (2) to the large amount of advertising given gratuitously by certain other cocoa manufacturers. After refuting the malicious statement which had been made to the effect that the company had been fined for adulteration, the Chairman went on to say:—

"A more pleasant subject is that of another gratuitous and splendid advertisement we have received from no less a person than the Chancellor of the Exchequer, who is, I shrewdly suspect, a habitual drinker of Dr. Tibbles' Vi-Cocoa. At all events, he is not an opponent of our company. When introducing the Budget on the night of the 21st April, Sir Michael Hicks-Beach, speaking of the increased and increasing consumption of cocoa in the country, made special reference to Dr. Tibbles' Vi-Cocoa in the following terms:—'Cocoa did remarkably well. Of course the receipts from the duty on cocoa are small, only £183,000, but out of that sum no less than £39,000 was an increase over the previous year. We imported last year three times the amount of manufactured cocoa that we did two years before that time, and this increase, I may add, is due I hope to some extent to the fact that people are turning their attention to cocoa, which I believe to be an admirable beverage. Not a little of it is due to the remarkable success of a certain well-advertised article which in gratitude to the maker I am half tempted to name.' Undeniably, Dr. Tibbles' Vi-Cocoa can claim the credit of the reference.

"I do not think we can desire any better testimonial as to the growing demand for cocoa in general, and for Dr. Tibbles' Vi-Cocoa in particular."

COMALTANA WINE

The most NOURISHING & INVIGORATING Wine ever introduced.

COMALTANA is prepared carefully and scientifically from, amongst other ingredients, Coca Leaf, Extract of Malt, and well-matured Port Wine.

Invalids and those suffering from Mental and Bodily Exhaustion find it invaluable.

It is popular among athletes. Gives strength and tone to the system. Lady cyclists especially find it invigorating and a preventive of fatigue.

Price 3s. per Large Bottle.

Sold by Chemists, Wine Merchants, and Stores.

PREPARED ONLY BY THE

COMALTANA WINE CO., Heckmondwike

Sample Bottle sent free to Medical Men on application.

HAY'S FOODS.

HAY'S FRUMENTINE.

TO YOUTHS, ADULTS, and to all who wish to excel in athletic exercises, such as CYCLING, BOATING, CRICKET, FOOTBALL, &c. &c. Try, either in the form of Porridge, or as a thickening for SOUPS, GRAVIES, &c. &c., the delicious and invigorating qualities of HAY'S FRUMENTINE.

HAY'S INFANTS' FOOD

TO EXPECTANT MOTHERS.

It is of the highest importance that, in order to lay the foundation of a vigorous, mental, and bodily constitution in after life the infant should during its Ante-Natal Existence receive the best and most beneficial maternal impressions. The attainment of this desirable object will, therefore, best be accomplished by attention to your own health, moderate exercise, cheerful society proper care of the digestive organs, and by adopting a Porridge diet of HAY'S delicious and LIFE-IMPARTING FRUMENTINE.

HAY'S FRUMENTINE.

TO NURSING MOTHERS who can bring up their children in the natural way,

USE HAY'S FRUMENTINE,

which imparts Life, Stamina, and Nourishment of priceless value to both mother and infant.

PRICE 6D., IN 2 LB. PACKETS.

HAY'S INFANTS' FOOD

TO THOSE MOTHERS less favourably constituted and who desire to feed their Infants on a bone, muscle, and brain-forming Food that will produce

A VIGOROUS GROWTH OF THE BODY GIVEN THEM

HAY'S INFANTS' FOOD,

In Tins, price 8d. and 1s. 3d each.

HIGHEST TESTIMONIALS From all the Medical Journals.

STRICTLY MEDICAL

DR TIBBLES' Vi-Cocoa

DR TIBBLES' Vi-Cocoa

DR TIBBLES' Vi-Cocoa

DR TIBBLES' Vi-Cocoa

DR TIBBLES' Vi-Cocoa

DR TIBBLES' Vi-Cocoa

The "LANCET" says:

"Vi-Cocoa must be assigned a place in the front ranks of really valuable foods, since it is the embodiment of all the numerous principles contained in Malt, Hops, Kola and Cocoa . . . of distinct value as a restorative and stimulative food."

The "BRITISH MEDICAL JOURNAL" says:

"Vi-Cocoa is a very palatable beverage of great stimulating and sustaining properties."

The "MEDICAL MAGAZINE" says:

"Medical practitioners will find a valuable weapon in Dr. Tibbles' Vi-Cocoa in combating the various conditions of nervous exhaustion and enfeebled digestion. The ingredients of which it is composed are carefully selected, and of undoubted strength and purity."

The "POPULAR MEDICAL JOURNAL" says:

Dr. Tibbles' Vi-Cocoa is an excellent combination of Kola and Cocoa; and it not only gives the nutritious and sustaining properties, but, having Hops incorporated with it, acts as a tonic and is soothing, while the addition of Malt neutralises all the starchy matter, and so considerably assists weak digestions."

From EDMUND A. ELLIOTT, M.R.C.S., L.R.C.P.

"I have tried Dr. Tibbles' Vi-Cocoa, and my patients are very pleased with it."

From Dr. T. H. SMITH, Royal Colonial Institute, Northumberland Avenue, W.C.

"I have much pleasure in testifying to the superior qualities of your Vi-Cocoa over any similar preparation in the market. I do this willingly and unsolicited, as I consider it a great boon to the public. I have personally experimented with the cocoas in the market, and find that the great drawback to all of them was the slow process of digestion and assimilation. The diastase in the Malt not only assists digestion in your Vi-Cocoa, but it also accelerates the digestion of other foods that are taken with the Vi-Cocoa. This I have personally tested, and can therefore speak from actual experience. Its wonderful recuperative power after exhaustion from fatigue is marvellous."

Merit, and merit alone, is what is claimed for Dr. Tibbles' Vi-Cocoa, and the proprietors are prepared to send to any reader who names this paper (a postcard will do) a dainty sample tin of Dr. Tibbles' Vi-Cocoa free and post paid.

Dr. Tibbles' Vi-Cocoa, 6d., 9d. and 1s. 6d. Can be obtained from all Grocers, Chemists, and Stores, or from Dr. Tibbles' Vi-Cocoa (Limited), 60, 61 and 62, Bunhill Row, London, E.C.

Coming Municipal Men.

II.—MR. REGINALD BROWN, A.M.I.C.E., *Assistant Surveyor, Ealing.*

MR. REGINALD BROWN, the subject of the present sketch, was born in the ancient city of Peterborough, which contains one of the grandest cathedrals in England, and about which much controversy has recently been waged, owing to the restoration of the noble west front. He was educated in his native city, and on leaving school was placed under the Borough Surveyor, Mr. J. W. Walshaw. This gentleman took a great interest in him, and initiated him into the mysteries of official life, and it is largely owing to the substantial knowledge he gained at Peterborough that he has advanced to his present responsible position. He stayed with the Borough Surveyor of his native town for a period of six years, and during this period large and important municipal works were carried out, amongst which may be especially mentioned extension of main drainage system, paving the streets in the centre of the town with granite cubes, wood, stone, and tar macadam, erection of Cottage Hospital, construction of new roads and private improvement works, and construction of extensive carriers on the sewage irrigation farm of over 300 acres. He had much to do with the management of the office—an essential part of the education of every future municipal engineer—and learnt habits of methodicity which he has not forgotten. Official routine cannot be successfully carried out unless the Surveyor's motto is "Method." Mr. Brown often recalls a splendid motto given to him by the road surveyor or road foreman, viz., "The path of duty is the way of safety," and we would suggest that if every aspirant for municipal honours took this motto to heart, they would find it of some use to them.

MR. REGINALD BROWN, A.M.I.C.E.

In 1890 he was appointed as Assistant Surveyor to the Brentford Local Board, now District Council, his chief being the late respected Mr. J. H. Strachan, A.M.I.C.E. In conjunction with Mr. Strachan, he carried out the erection of a hospital for infectious diseases, and the Board was so pleased with the manner in which the work was carried out that an honorarium of £20 was voted to Mr. Brown as a recognition of his services in connection therewith. He also carried out large works of drainage and private improvements, besides the inspection of all buildings erected under the Building Bye-laws, and the measuring up and certifying the accounts of the various contractors. He also had experience in the working and maintenance of sewage pumping machinery and steam boilers; the treatment of sewage by the "chemical process" with alumino-ferric and lime, and the disposal of the sewage sludge by filter presses, worked by compressed air, the resultant cake being either disposed of by sale, given away, or digging into the surrounding land. Mr. Strachan always spoke very highly of his services. He was awarded the certificate of competency in sanitary knowledge of the Sanitary Institute in 1892.

About six years ago he was appointed to his present position, and during his term of office he has been engaged upon almost every duty which is likely to fall to the lot of a municipal engineer. Ealing is a favourite western suburb of London, and its growth is almost phenomenal. Its population now exceeds 33,000. It is considered one of the healthiest places around London, the death-rate last year being as low as 9·3 per 1000. The engineer's and surveyor's department of a rising town has always plenty to do to keep pace with the requirements of the district. Besides the usual routine inseparable from a public position, he has been engaged upon extensive works of sewerage and storm-water drainage, enlargement of sewage works, enlargement of electric installation buildings, the construction and management of refuse destructors, fixing Galloway and multitubular boilers, erection of hospital lodge, park-keeper's lodge, workmen's cottages, stabling accommodation, public baths; preparation of plans, specifications, and estimates for and superintending the making up of private streets and the apportionment of the expenses thereof; the examination of all plans for new streets and buildings, and the inspection of same during construction; also the drainage of new and old buildings, besides numerous

other works which require attention in a public office. Ealing, as a town, almost stands unique in the possession of municipal buildings. It has magnificent offices, of which any town might well be proud, public swimming baths and slipper baths, the swimming baths being utilised in the winter for gymnastics and other purposes, the swimming space being covered with strongly-constructed and movable wooden floors; large stabling accommodation for the horses belonging to the Authority, and mechanics' shops for the necessary repairs to plant; fire station, sewage farm, sewage-disposal works, electric lighting station, and refuse destructor works, where the sewage sludge is, and has been for years, burnt with the house refuse.

Mr. Brown obtained the certificate of competency to discharge the duties of a Municipal Engineer from the Incorporated Association of Municipal and County Engineers in 1894. This certificate is considered, and rightly too, to be a very valuable one to the younger members of the municipal engineering profession, as the subjects embrace levelling, surveying, hydraulics, sewerage, and sewage disposal works, water supply, road-making, building construction, Building Bye-Laws, Sanitary Science and Municipal and Local Government Law. He was elected a Member of the Sanitary Institute in 1895, and an Associate Member of the Institution of Civil Engineers in 1897. He has also been very successful as a professional coach for the examinations of the Sanitary Institute and the Municipal and County Engineers.

From the above sketch of Mr. Brown's career, it is apparent that he must be the possessor of great energy and perseverance, and when elected to a chieftainship, he will no doubt be able to give a good account of his stewardship. His promotion cannot be far off, as he has already been amongst the finally selected for the Surveyorship to the District Council of Southall-Norwood, Middlesex; the Borough Engineer and Surveyorship of Reigate, Surrey, and quite recently ran very close for the Vestry Surveyorship of Stoke Newington, out of fifty-three candidates.

THE MANCHESTER REPORT ON SYSTEMS OF SEWAGE PURIFICATION.

(Continued from page 508.)

BARKING OUTFALL WORKS.

Chemical Report.—The quantities of lime and iron sulphate (four grains of lime and one grain of sulphate of iron per gallon of sewage) added to the sewage are so small that this can scarcely be called a chemical precipitation. They merely assist clarification and subsidence. The effluent does not comply with the conditions one and three laid down as above.

The results obtained by the use of the coke breeze filter of one acre upon the effluent produced by the above treatment were very satisfactory, as stated by Mr. Dibdin in his printed report, and according to the information received from the officials present. The filter being in course of alteration, our chemist could not take samples. The purification is stated to be 78 per cent. removal of the organic matter, and also that the organic matter remaining in the filtrate "is in such a condition that no signs of after-putrefaction are exhibited however long the filtrate may be kept either diluted or undiluted, in open or closed bottles." The sample of tank effluent before filtration examined by our chemist is worse as regards organic impurities than the effluent from the Davyhulme Works.

Report as to Cost and General Working of Filters.—This filter created a very favourable impression on the deputation on account of the reported efficiency of its working and its apparent freedom from silting up. It is triangular in shape, having the brick structure of a disused culvert on one side, and the river wall on another. These two sides were banked and puddled with clay; the base of the triangle was then constructed with part of the excavated material from the centre, and also puddled with clay. The bed of the filter is a natural formation of peat and peaty clay, and as this material prevents the free passage of water it was found not to be necessary to puddle or concrete it. The bottom is covered to a depth of 3ft. with pan breeze; these cinders were obtained from the gas-works near at hand, at a cost of 3s. 3d. per ton. The proximity of the filtering medium, and the natural preparedness of the bottom and two of the sides of the filter, render it unreliable as a guide to cost for such filters in Manchester. Its area is one acre, and the cost of its construction was £1494 2s. 5d. Messrs. Worth and Crimp, who constructed it; Mr. W. J. Dibdin (late Chemist to the London County Council), who initiated it, and analysed the results of its action; and Mr. Thudichum (the Assistant Chemist), who personally carried out the experiments and measured the quantities, all agree that it is capable of filtering one million gallons of tank effluent per day, and that after five years' working it is free from clogging, and as capable of filtering that quantity as ever. There are reasons to think that the original holding capacity has been somewhat reduced, but its working capacity is not impaired. Its depth is now being doubled, in order to experiment as to whether an increase of power and effect will follow from added depth. Messrs. Worth and Crimp give valuable testimony concerning its power of endurance. They say "that this filter is apparently capable of continuing its function for an indefinite time." Mr. Dibdin affirms "that the lives of such filters are practically without limit." As to maintenance and management, Mr. Dibdin also states that "when such a filter is fairly started, and working systematically, little fear need be felt that it will go wrong; it does not require constant renewal or alteration, but, like a good engine, it wants watchful care to enable it to give the best results." When the power of the filter appears to be diminished, a short period of rest restores it to its original condition.

FRIERN BARNET SEWAGE WORKS.

The deputation visited these works on Wednesday afternoon, the 22nd December, 1897. The visit was not included in the original programme. The Committee were shown over the works by the foreman, and were subsequently met by Mr. E. J. Reynolds, the surveyor to the Friern Barnet Urban District Council, who kindly afforded every assistance and explanation to the Committee, and also supplied the accompanying plan of the works, which are situated on the south side of the district, and within 100 yards of a small brook, into which the effluent flows. The works were completed at the end of 1886. The district has a separate sys-

tem of drains for storm water, and almost all the houses have a dual system of drains. The works comprise three precipitation tanks, each of a capacity of 70,000 gallons. There is a penstock or valve opposite to each tank, so that one or more can be worked at pleasure. Four artificial filter beds are placed below the tanks, having a total area of 6976 yards super. These beds are 6ft. in depth, and are constructed as follows :—2ft. 6in. of coarse burnt clay, 3ft. of fine burnt clay, coke breeze, and sandy soil, mixed in equal proportions, and screened to pass through ¼in. mesh, the top being covered with 6in. of sandy soil. The dry weather flow of sewage is about 220,000 gallons per day, and the population contributing to the works, including Clerkenwell (detached), is about 10,000 persons. The sewage is first screened, and afterwards treated to four grains of Buxton lime per gallon. It is then thoroughly mixed, and receives a dose of one grain per gallon of sulphate of alumina. It is again mixed by passing through a salmon ladder, and in this condition it flows into the precipitation tanks, from whence it overflows through coke screens into an open channel, and thence to the filter beds before described. The filters are worked alternately four days each at a time. At present the filters treat about 126 gallons per super yard per day.

The surface of the filters is occasionally harrowed with hand harrows before the sewage is turned on. The sludge resulting from the precipitation is run by gravitation to a well, from which it is pumped upon the land. Sludge presses were provided, but are not now in use. The original cost of the works, including tanks, filters, and machinery, was £16,000.

Samples of sewage and tank effluent were obtained, and the following is the result of the analysis of same :—

Description of Samples.—Crude sewage, December 22nd, 3.20 p.m.—Considerable amount of brown suspended matter; sample taken shortly after stirring the sewage. Fœtid smell.

Tank Effluent, December 22nd, 3 p.m.—Turbid, with grey suspended matter. Sewage smell.

Filtered Effluent, December 22nd, 3.15.—Bright and clear. No smell.

Analytical Numbers.

Oxygen absorbed, 4 hours.	Grains per gallon.
Sewage (shaken	6·23
„ (settled)	5·28
Tank effluent	2·81
Filtered effluent	·30

Oxygen absorbed, 3 minutes (Incubator Test.)

	Grains per gallons. Before incubator.	After incubator.	Percentage increase.
Sewage (settled)	2·17	5·56	150
Tank effluent	1·27	3·43	170
Filtered effluent	·096	·075	—

Remarks.—Both the sewage and tank effluent become very foul in the incubator. The filtered effluent remains perfectly sweet.

Ammonia— Free and Saline.	Grains per gallon.
Sewage (shaken)	5·30
„ (settled)	5·40
Tank effluent	5·35
Filtered effluent	·025

Albuminoid.

Sewage (shaken)	1·16
„ (settled)	·82
Tank effluent	·56
Filtered effluent	·05

Chlorine—

Sewage	11·0
Tank effluent	7·2
Filtered effluent	7·4

Remarks.—The sewage is of a domestic character. The tank effluent is of a highly putrescible character, containing a large proportion of albuminoids. The filtered effluent is of an excellent quality, showing signs of active nitrification, nitrites being present in it, which are not shown in the tank effluent. The filtered effluent contained nitrogen as nitrates and nitrites to the extent of ·55 grain per gallon. The disappearance of the free ammonia is noteworthy, being due probably to the layer of soil on the filter, such a layer being shown by laboratory experience to be capable of retaining and possibly oxidising the free ammonia. A portion of the soil from the filter was examined, and found to be capable of yielding considerable quantities of albuminoid nitrogen.

Chemical Report.—The real purification is effected by the filter beds, but the sewage being exclusively of a domestic character, and the relative area of the filters to the flow of the sewage so great—namely, equal to about 150,000 gallons per acre per day, passing at the rate of 600,000 gallons per acre—no conclusion can fairly be drawn with the conditions prevailing in Manchester. The analytical figures show, however, what excellent results can be obtained from sewage mainly of a domestic character by the use of an ample area of biological filters.

Report as to Cost and General Working of Filters.—This filter is about 1½ acres in extent, and was built in four sections on sloping ground, which necessitated the building of a deep and strong wall at the end of each section. Its depth is 6ft. and the material is graded—two layers of burnt clay, one of coke breeze, and a top covering of soil 6in. in depth. Its cost was £2847, which is £1898 per acre. It is of larger area than is required at present, and only one section at a time is used. It is now filtering 126 gallons per square yard per twenty-four hours. It was completed in 1886, has worked without needing repair ever since, and is filtering an effluent from very strong domestic sewage.

(*To be continued.*)

TEDDINGTON.—At the last meeting of the Urban District Council a letter was received from the Local Government Board, stating that a complaint had been received from a ratepayer of the non-removal of house refuse. In the course of the reply ordered to be sent, it was stated that the refuse was now collected fortnightly instead of every three weeks as formerly. There were 2270 houses in the district, and complaints were under 2 per cent. One of the members suggested that the Council should adopt the system in force at Broadstairs and Kingston, by which householders put their refuse on to the kerbing every morning in pails, and thus had it removed every day. This, he asserted, would save a great deal of expense to the rates, and prove far more efficacious than the present method.

PRESENTATION.

An interesting gathering took place at the Guildhall, Hereford, on Saturday, when a number of the Corporation officials and friends met to present a testimonial to Mr. James Taylor, who has held the post of Sanitary Inspector for the city for eleven years, and who has resigned his official capacity in order to embark in business on his own account as an architect and sanitary engineer.

The presentation, which consisted of a gold watch and illuminated address, was made by the Town Clerk, who referred in the course of an appropriate speech to the excellent way in which Mr. Taylor had discharged his duties as Sanitary Inspector for the past eleven years.

The address was surmounted by the city arms, and bore views of the Old House and the Cathedral from the river. It was worded in the following terms :—"To Mr. James Taylor : We, the undersigned officials of the Hereford Corporation, ask your acceptance of the accompanying gold watch as a slight token of our esteem and regret upon the occasion of your resigning the position of Inspector of Nuisances for the city of Hereford. During the nearly eleven years that you have held this appointment and it has been our pleasure to associate with you, your unfailing courtesy and tact, accompanied by a conscientious discharge of your duties, have gained for you many friends, and it is with every wish for your future prosperity and happiness in your new sphere of work as an architect and sanitary engineer that we present you with this testimonial.—(Signed) C. B. Beddoe, Clerk of the Peace ; E. Bellerby, City Treasurer ; A. Bellingham, Hospital Matron ; Joseph Carless, Town Clerk ; James Cockcroft, Librarian ; James Davies, Clerk to the Justices ; J. B. Fitzsimons, Hospital Medical Officer ; John Lambe, City Coroner ; H. C. Moore, Assistant Medical Officer ; Daniel Ovens, Market Inspector ; John Parker, City Surveyor ; William Parlby, Gas Manager ; Frank Richardson, Chief Constable ; Richard Rogers, Slaughter-house Manager ; Samuel Rogers, School Attendance Officer ; H. V. Sandford, Medical Officer of Health ; A. B. Smith, Market Collector ; J. A. Spreckley, Surveyor's Accountant." The handsome gold watch bore the following inscription :—"Presented to Mr. James Tayor as a mark of esteem by his co-officials of the Hereford Corporation, March, 1898."

A NEW GAS BURNER FOR STREET AND DOMESTIC LIGHTING.

There is probably no other firm in existence who have done more to extend the value of gas for illuminating purposes, whether for public or private use, than the Incandescent Gas Light Company have done by the introduction and development of the Welsbach burner, which, with its special form of mantle, is superior in efficiency to that of any other gas burner for ordinary use. It will interest many of our readers, however, to know that the company have not been content to rest on their oars, but have still further improved their claim to be the pioneers in the development of gas lighting, by effecting further considerable improvements on the burner used in conjunction with a mantle.

Briefly, it may be stated that the old Welsbach burner had an efficiency of 17 candles per cubic foot on a consumption of 3½ cubic feet of gas per hour, but the new burner is claimed to give an efficiency of 30 candles per cubic foot whether a cubic foot or more is consumed, or with a consumption of 5 cubic feet per hour, such as given by ordinary burners, an illuminating power of 150 candles is produced, so that the efficiency of the new light is claimed to be almost double that of the old. There is also this difference in the new burner, and that is that no chimney is required to be used in conjunction with it.

We have had an opportunity of seeing the new light, and believe that the claim made for it by the company is quite justified, and exceeds the expectations of those engineers who had been apprised some months ago of its proposed introduction. The price of the new burner is to be similar, we understand, to that of the old, so that it behoves our readers who have control of street lighting to withhold the purchase of the old pattern for a few weeks, in order to take advantage of the improvement.

Incidentally, we may also mention that this company have also devoted their attention to improvements in oil lamps by the invention of a special burner with mantle applicable thereto, and have produced a light having an efficiency higher, we believe, for the same amount of consumption of oil than that of any other known type of oil-burner. In smaller towns and villages where gas is not obtainable for street lighting the introduction of this oil-lamp will be, we predict, very popular.

We may add that the new gas burner is to be offered for sale to the public during next month, and we venture to state that it will prove a formidable rival to the electric light. Those of our readers who require to make themselves *au fait* on the subject should communicate with the company, whose offices are in Palmer-street, Westminster, S.W.

ALLOA PUBLIC BATHS.

New public baths have just been erected at Alloa. The building contains the following departments, viz. :—Billiard and amusement-rooms, swimming pond and accessories, first and second-class plunge baths, Turkish baths, Russian bath, and gymnasium. On the ground floor, and immediately on each side of the main entrance, are the billiard and amusement-rooms, and beyond the entrances to these rooms is the booking and towel office. A wide corridor in front of this office gives access to the other departments of the building. The swimming-pond hall, extending from this corridor through a vestibule, is 98ft. by 50ft., having an open timber roof averaging 25ft. high from the floor. The pond is 75ft. by 32ft. On each side are dressing boxes. A dressing-room and washing-room for school children are provided at the entrance end, and a washing-room for adults, with the usual conveniences, is situated close to the club-room. The second-class plunge baths—seven in number, on a slightly lower level than the pond—are entered from the main corridor. The first-class baths are on an entresol floor immediately over the booking office, and are reached from the same corridor by a stair. The Turkish bath department, and the Russian bath adjoining, are at the far end of the swimming pond. The gymnasium, 76ft. by 28ft., having an open timber roof, with an average height of 22ft.,

occupies the whole of the first floor of the front building over the billiard and amusement-rooms, and is provided with the necessary dressing-rooms. A gallery is placed at the one end. The washing-house and laundry are placed behind the heating department. All the rooms have been fitted with lamps for electric lighting; this work has been carried out by Messrs. Mavor and Coulson, Limited, Glasgow. Messrs. Burnet, Son, and Campbell, of Glasgow, were the architects.

ADULTERATION IN MIDDLESEX.

FROM a return presented to the Middlesex County Council of the working of the Food and Drugs Act for the year ended March last it appears that 1844 samples of various articles were analysed during the year, of which only 87 were found adulterated, making a percentage of 4·6, as against 7·8 for the preceding year in Middlesex. The percentage throughout the country is 9·2. On this point it may be remarked that the percentage system is very misleading in some respects. For instance, salad oil is credited with 100 per cent. adulteration, the fact being that only one sample was taken, and that found impure. Similarly separated milk figures at 50 per cent., *i.e.*, two samples were taken and one found bad; and all will be interested to learn that though rhubarb pills have a report of 66·6 adulteration in Middlesex, there were only three samples, taken and one found wrong.

As usual the milk vendors came in for a large share of attention, 972 samples of the genuine article having been taken, of which fifty-two were found incorrect. Butter fared better, half that number being taken and only sixteen found adulterated. Beer comes out with a clean sheet, by reason probably of the fact that no one in authority is able to state what beer is. But brandy shows 50 per cent. adulteration, gin 25 per cent., rum 100 per cent., and whisky only 9·1. Rum evidently wants looking up again. The rising generation will learn with delight that liquorice, ginger bread, ginger beer, cocoa-nut chips, saveloys, and castor oil have all been found the pink of perfection. And Dr. Tibbles, whose name has been prominently before the public of late, will be pleased to learn that his Vi-Cocoa has passed through the analyst's crucible and stood the test with credit to itself and its maker's reputation.

Our old friend, hokey pokey, too, has secured a certificate, and, if not pleasant, may be held to be inocuous if taken in moderation. The cost of all this examination and analysis was £1588 3s. 4d., of which the analyst took £1073 2s. in fees, leaving the surplus to the smaller fry; £154 3s. 6d. was received back in the shape of fines from offenders, of whom 93 suffered out of 121 prosecuted. In the western district of Middlesex, where the energetic Mr. Walter H. Tyler holds sway, 124 samples were taken during the past year, of which seven were found adulterated and two inferior. Mr. Tyler took brandy and whisky for analysis, and it must be recorded that some of it was found bad. He also took milk to the extent of 62 samples, of which two were found adulterated.

THE SANITARY INSTITUTE.

At an examination in Practical Sanitary Science, held in London on May 6th and 7th, twelve candidates presented themselves. The following five candidates were granted certificates in Practical Sanitary Science:—A. S. E. Ackermann, H. Bates, W. C. Henley, J. Hipkin, G. T. I. Oliver.

At an examination for Inspectors of Nuisances, held in London on May 6th and 7th, 109 candidates presented themselves. The following 64 candidates were certified, as regards their sanitary knowledge, competent to discharge the duties of Inspectors of Nuisances:—

D. Bagshaw, W. Barker, W. J. Bates, G. Best, H. E. Brown, T. L. Burrell.

H. Callow, Miss E. H. Cordner.

G. E. J. Davis, S. N. Davy, J. E. Dowell, H. L. Dunkin. E. H. Faragher, E. Few.

E. D. Gedge, W. H. S. Gowen, W. J. Griggs, F. A. Gwillim.

H. R. Hardy, W. Hawke, T. W. Hull, H. L. Hyde. I. R. Jones, W. D. Jones, W. P. Jones.

A. E. Lang, A. J. Lester, C. M. Longden, P. W. Luke.

Miss A. Malone, S. S. Markham, Miss E. L. Maynard, S. J. Maynard, F. W. Melhuish, M.R.C.V.S., Miss C. Mennell, G. Mitchell.

Miss C. A. Nevile, E. A. Norman.

J. H. Pearson, Miss M. E. Piggott, Miss K. A. Platt, W. C. Portman, A. G. Potter, J. J. Pratt.

A. S. Quelch.

J. H. Reynolds, A. M. Robertson.

E. W. Sandford, E. E. Scott, Miss E. Stewart.

H. Taviner, C. R. Thomas, H. J. Toogood, H. S. Toogood, Mrs. E. C. Townsend, T. Tribe.

G. S. Walker, G. R. Weeks, J. Wells, J. West, T. W. Williams, C. N. Wilson, Miss T. F. Wilson, I. Worrow.

Improvement in Incandescent Light.—Although the superiority of the incandescent gaslight, both from an economical point of view and as an illuminant, over the ordinary gas jet is generally recognised, the fragile character of the incandescent mantles has hitherto proved a serious obstacle to the adoption of the incandescent system of gas-lighting in works or other situations subject to more than ordinary vibration. By a very simple device, which has been designed and patented by Mr. W. R. Clay, of Bolton, this serious objection to the use of the incandescent gaslight in engineering and other works is said to have been practically overcome, as by this arrangement the effect of shock or vibration upon the mantles of incandescent gas burners is altogether neutralised. The invention is quite novel, and consists simply in coiling a portion of the pipe supplying gas to the burner in such a manner as to form a resilient spring—an adaptation of the gas pipe that has never before been attempted. The usefulness of the arrangement will be apparent when it is stated that with a copper pipe coiled as above described, gas burners can be used in any situation, and the mantles preserved to more than their average length of life. Another special point is that as no india-rubber is used in its construction, the fitting does not come under the ban placed by the fire insurance companies upon anti-vibratory fittings other than those made entirely of metal.

Sanitary Inspectors' Associations.

YORKSHIRE.

THE members of this branch of the Sanitary Inspectors' Association met on Saturday afternoon in the Council Chamber of the Leeds Town Hall, Mr. D. Travis presiding. Dr. J. Spottiswoode Cameron delivered a lecture on "The Economic Measure of Sanitary Progress in Terms of Lives Lengthened during Years of Robust Manhood." Statistics, he said, proved that the child born in England had an expectation of forty-one years of life; the French child's expectation was forty years, and the child born in Sweden thirty-nine years. Figures showing the number of persons per 1000 of the population who died in various localities per annum could not be taken as a perfect criterion of the sanitary condition of such locality. If an exceptional proportion of the people in a certain place were between the ages of, say, sixteen and fifty, the death-rate in such a place ought to be less than amongst a population largely composed of young children and old people. The death-rate was higher in manufacturing towns than in rural districts. Taking a recent period, the Registrar-General's returns showed the death-rate in England and Wales to have been 19·1 per 1000 per annum. In the twenty-eight largest towns during this period the death-rate was over 21, whilst in rural districts it was only 17·6. Small-pox, measles, and scarlet fever were more fatal in towns than the country. There was not the same difference, however, in regard to typhoid, which depended so much on the quality of drinking water and milk supply. Although our towns were becoming more crowded every year, and although the average acreage of land per man in the country was gradually diminishing, yet the lives of the people were being more effectively preserved. Whilst the death-rate amongst old people was increasing, there were more people who lived to be old than was formerly the case. In other words, the death-rate amongst the young and middle-aged was gradually diminishing. Fewer deaths occurred to-day from consumption. The decline in this disease in women was particularly marked. This was no doubt due to the improved sanitary conditions of the homes of this country. The mortality tables showed a steady increase in the number of survivors at mature ages. A youth of twenty some forty years ago had an expectation of twenty years of further life, and a maiden of twenty-one years. These had now been increased to twenty-three and twenty-five years. The lives of weak people had been prolonged, and fewer people died in middle age. Improved sanitation had brought this very desirable change about.

A discussion followed, in which Mr. LINDLEY, Batley; Mr. DARLEY, Leeds; Mr. DENHAM, Tadcaster; and others took part.

A hearty vote of thanks to Dr. Cameron concluded the proceedings.

BARMOUTH.—The waterworks, which have been carried out at a cost of nearly £28,000, are now completed, and the formal opening will take place on Saturday, June 11th. The ceremony was to be performed by Mr. T. W. Russell, M.P., last week.

General News.

BRIGHTLINGSEA.—The Urban District Council is applying for sanction to purchase the local waterworks at a cost of £4500.

PUDSEY.—At a recent meeting of the Urban District Council, sketch plans for public baths, estimated to cost £4000, were considered, but it was decided that the present time was inopportune for such an outlay, and the whole project dropped.

ILFORD.—A Local Government Board inquiry has been held in reference to the Urban District Council's application for sanction to borrow £12,350 for public street improvements and surface water drainage; £1385 for private street improvements; and £700 for an underground convenience in the Broadway.

EAST SUSSEX.—The County Council has decided to appoint a Sub-Committee of the Sanitary Committee to consider what steps it is desirable to take in order to secure the provision of hospitals for infectious diseases throughout the administrative county, with authority to communicate and confer with the District Councils on the subject.

KEIGHLEY.—The Council has agreed to exercise the clause of the local Bill as to the closing of existing registered slaughter-houses, and providing compensation therefor, the reason given for this step being that the Tuberculosis Commission had reported in favour of increased powers being granted Local Authorities in this behalf.

LEITH.—The deaths registered within the burgh during the month of April numbered 119, being a decrease of 18 on the preceding month, and a decrease of 9 on the corresponding month last year, and showing a death-rate of 18·9 per 1000. Infectious disease accounted for 5 deaths, viz., small-pox, 1; scarlet fever, 1; diphtheria, 1, erysipelas, 2.

RICHMOND (SURREY).—The Town Council has unanimously passed a resolution in opposition to the proposed light railway from Kew to Hampton Court. A special meeting was held to consider the matter. There have also been meetings of the Richmond Select Vestry and tradesmen's organisations, all of which have decided to join in opposing the scheme.

KNARESBOROUGH.—The Sanitary Committee has been authorised to hold a local inquiry into the necessity for the establishment of an isolation hospital or hospitals for the use of the inhabitants of Knaresborough urban and rural districts. The Harrogate Corporation has expressed willingness to consider a scheme for combining with Knaresborough.

LANCASTER.—Dr. Parker, Medical Officer for the Lancaster Rural District Council, in his annual report, expresses pleasure that several matters which have long required attention are receiving consideration:—The provision of hospital accommodation for infectious diseases, the water supply of portions of the district, and the visitation of notified cases of infectious disease. The appointment of an assistant Sanitary Inspector is urgently required. Regulations under the Local Government Board Order have been adopted for dairies, cowsheds, &c. The time is ripe, he declares, for the legislative regulation of traffic in milk and flesh.

KELSO.—The Heatherhope water scheme has been postponed.

REDCAR.—New water mains are to be laid in a portion of High-street, at a cost of £72.

HALIFAX.—The Town Council has resolved to expend the sum of £250 on waterworks.

DONCASTER.—The Corporation hopes shortly to complete a satisfactory scheme for small-pox patients.

SUNDERLAND.—The surveyor has been instructed to prepare plans for a hospital at as early a date as possible.

BIRMINGHAM.—At a recent meeting of the Birmingham Association of Mechanical Engineers, Mr. E. A. Lees delivered his illustrated lecture on "The Welsh Water Scheme." The lucid explanation of the enterprise, and the numerous interesting particulars furnished by Mr. Lees, were much appreciated, and a hearty vote of thanks was accorded to him.

BELFAST.—A deputation from Belfast, consisting of Councillor Corr, Mr. F. C. Johnston, Mr. F. Robinson (Deputy Clerk to the markets), and Mr. J. Munce (Engineer to the Belfast Corporation), have been in England and Scotland recently, inspecting the public abattoirs. This visit of the deputation is in view of the large additions to the abattoirs which have been authorised by the Belfast Corporation.

DEVONPORT.—The Borough Council has referred to a Committee an offer which it has received to provide the town with one of Willoughby's refuse destructors, capable of dealing with from 70 to 100 tons of refuse per day, the Council to work the destructor for three months, and if it approved of it at the end of that time to purchase it for £2000. If the Council did not approve of the destructor it would be removed, and no claim made on the Council. The destructor could also be used for stonebreaking and for a supply of steam to a disinfectant apparatus.

EDMONTON.—Dr. Green, the Medical Officer of Health, in his annual report to the Urban District Council, again refers to the need for an isolation hospital:—"The need of adequate provision is felt every year, and the cost and difficulty of providing it will, I fear, increase with delay. During the year to which this report relates, the want of such provision was most keenly felt in dealing with the outbreak of diphtheria, there being absolutely no accommodation at the disposal of the Council."

HAMPTON.—At the last meeting of the Urban District Council the Medical Officer reported that he had examined five samples of well water, all of which were found to be bad and unfit for domestic use. Accompanied by the Inspector he had visited the dairies, cowsheds, slaughter-houses, and bakehouses in the district. He had reason to find fault in some instances, but he had since learnt that the defects had been made good. Numerous complaints, written and oral, had come to his knowledge as to the excessive amount of dense smoke emitted from the shafts of the water companies during the past month. The Inspector was taking notes of the occasions when this happened. It was resolved to serve the necessary notices on the companies to abate the nuisance. With the exception of a few cases of measles there was no notifiable disease in the district.

LOUGHBOROUGH.—A loan of £3000 is to be raised to meet the cost of a new filter, extension of mains, &c.

CASTLEFORD.—A special Committee has been appointed to give their immediate attention to the question of water storage.

LLANELLY.—The Borough Council has purchased certain lands at Ystradfai and Pandyfach required for the new waterworks, at over £2000.

MANCHESTER.—In reference to a statement which appeared in last week's issue that no cases of small-pox has been reported in Manchester for a little over a year, Mr. Geo. A. Stephenson writes:—"If you refer to the Manchester weekly health return for the week ending May 7th, 1898, you will find that no cases have been reported in Manchester since May, 1896."

Personal.

MR. H. R. BROWN has been appointed Medical Officer of Health for the borough of Maldon.

MR. R. BROWN has been appointed Medical Officer for the first district of Hackney union.

MR. W. H. COOPER has been appointed Medical Officer for the Stavely district of Kendal union.

MR. E. J. LEGG has been appointed Inspector of Nuisances for the borough of Christchurch.

DR. BURGESS has been reappointed Medical Officer for Hoole, at a salary of £35 per annum.

MR. D. FRASER has been appointed Medical Officer of Heath for the urban district of Buckley.

MR. G. B. SIMPSON has been appointed Medical Officer for the Lastingham district of Pickering union.

DR. R. J. SPEAKELING has been reappointed Medical Officer of Health for the borough of Bootle.

DR. C. J. VLIELAND has been appointed Medical Officer of Health for the urban district of St. Thomas.

MR. WM. OXTOBY, A.M.I.C.E., Poplar, has been appointed Surveyor for the Vestry of Camberwell.

MR. W. T. WOOLDRIDGE has been appointed Inspector of Nuisances for the rural district of Epsom.

MR. G. C. H. FULTON has been appointed Medical Officer of Health for the urban district of Eston.

MR. E. E. LLOYD has been appointed junior-assistant Medical Officer at the Fulham union infirmary.

MR. G. COLE has been appointed Medical Officer for the sixth district of the parish of Nottingham.

MR. ARTHUR F. TURNER has been appointed Medical Officer of Health for the borough of Tewkesbury.

DR. ARTHUR NEWSHOLME, Brighton Medical Officer of Health, has been invited to become one of the Examiners in Preventive Medicine at Oxford University. The examination is held once a year, in November, and lasts about two days.

MR. G. B. HILLMAN has been appointed Medical Officer of Health for the urban district of Whitwood.

MR. J. W. ROWLEY has been appointed Inspector of Nuisances for the urban district of Ashley Woulds.

MR. J. F. LAMB, of the Engineer-in-Chief's office of the General Post-office, has been elected an Associate of the Institution of Electrical Engineers.

MISS ALICE TREBAY has been appointed female Sanitary Inspector for the Hackney Vestry. This lady received her training at the National Health Society, and holds its diploma.

THE Local Government Board has sanctioned the appointment of Dr. W. Monckton as Medical Officer of Health, and of Mr. Moss Flower as Surveyor and Inspector for the district of Portishead.

MR. T. FENN, who for four years held the position of Surveyor and Inspector of Nuisances under the Soothill Upper District Council, has secured an appointment as Surveyor to the Belper District Council.

MR. ISAAC SMITH, for eighteen years Inspector of Nuisances for the borough of Lancaster, died at his residence on the 8th inst. Deceased retired from public life two years ago on account of ill-health. He was sixty-one years of age.

MR. WILLIAM LINDLEY CATLIN, M.W.W.A., late Clerk of Works of the Haverhill (Suffolk) Waterworks, has been appointed Engineer and Manager of the Faversham Water Company, Limited, in place of Mr. R. Dauney, resigned.

AT the recent London examination of the Municipal and County Engineers' Association, we are pleased to find among the successful candidates our old contributor, Mr. Ernest Worrall, now located as Surveyor to the Local Authority at Penmaenmawr, North Wales. We congratulate Mr. Worrall on his success.

MR. J. CORBEN, Sanitary Superintendent to the Corporation of the city of Cape Town, having received four months' leave of absence, is on his way for a visit to the old country. He has been in South Africa over six years; prior to his present appointment he was the Chief Sanitary Inspector at Southampton, at which place he will see a marvellous change upon his return.

Sewerage Schemes.

[TO MUNICIPAL ENGINEERS AND SURVEYORS.—The Editor will be pleased to receive items for publication relating to sewerage schemes projected or inaugurated, together with explanatory diagrams or photographs. The former should be drawn and lettered in black ink.]

THE Urban District Council of Portslade (Sussex) has decided to apply to the Local Government Board for sanction to borrow £19,500 for the drainage of the district.

THE Waterford Corporation has, we understand, adopted a city sewerage scheme at a cost of £40,000. The tender of Mr. Smith, of Belfast, for £10,000 for portion has been accepted.

A SUB-COMMITTEE of the Sanitary Committee of Stoke-on-Trent Town Council has been appointed to consider whether it is desirable to deal with the Trent Vale sewage in any other way than at present.

CARLISLE Town Council has decided to adopt a bacteriological filter on the Dibdin system for the sewage disposal of the city, and the Surveyor (Mr. Henry C. Marks) is to prepare plans for the necessary plant.

A LOCAL Government Board inquiry has been held at Cossal into the application of the Rural District Council of Basford for sanction to borrow £2300 for the purposes of sewerage and sewage disposal for the parish of Cossal.

THE Local Government Board has written the Portishead District Council with reference to the application of the Council to borrow £3000 for the purposes of sewerage, stating that before deciding upon the application the Board would direct a local inquiry on the subject.

PLANS of a new scheme of sewerage for the drainage of Dorchester (where the Frome is being polluted), on which so much depends for the effective treatment of extensive suburban districts, are about to be submitted to the Corporation. These out districts will then be, in all probability, taken in the borough.

THE Thorpe-le-Soken Parish Council recently had before it a new system of sewerage for the parish, prepared by Mr. T. H. Gold, surveyor to the Tendring Rural District Council. The Essex County Council is about to make up the main road through the parish, and wishes to have the drainage done first. Mr. Gold's estimate of the cost of his proposal is £750.

AT the Manchester County Police-court, on Thursday, the 12th inst., Mr. Yates, Q.C., the stipendiary magistrate, refused to sanction the application of the Manchester Corporation for a further extension of time to enable it to carry out the order made by the Court in September, 1896, for the completion of the sewage works.

THE Native Guano Company is endeavouring to comply with the new rules of the Thames Conservancy Board and produce a better effluent at the Kingston works. By way of experiment the company has recently constructed a small coke filter, the effect of which is considered so satisfactory that the directors have decided to construct two others on a larger scale, each 20ft. by 11ft. The one will be filled with panned breeze, *i.e.*, actual ashes, as a filtering medium, and the other with coke breeze, *i.e.*, made-up coke, so as to compare the results. It has been found that in the effluent passed through the small experimental filter already mentioned the amount of ammonia albuminoid was reduced by one-half. Even better results are anticipated from the larger filters. Similar filters are used at the Aylesbury works.

THE Local Government Board has sanctioned a loan to the Tring Urban District Council of £5000 for sewerage and sewage disposal works.

THE Woolwich Local Board has decided to support the application of the Lee District Board for the construction of a proper system of main drainage for Charlton on the north side of the Woolwich-road.

THE Town Council of Canterbury has adopted reports recommending application to the Local Government Board for £20,000 for sewerage improvements, £3000 for works at the sanatorium, and £1000 for the erection of workmen's cottages at the sewage farm.

THE ceremony of cutting the first sod in connection with the new drainage scheme to be carried out at Popesdown, a suburb of Bournemouth, took place on Thursday afternoon, the 12th inst. The works are to cost about £20,000, and the ceremony was performed by Mr. W. Bolton, ex-chairman of the Urban District Council. A public luncheon followed.

AT the last meeting of the Enderby Sanitary Authority a communication from the Local Government Board in reference to the proposed sewerage scheme, and the desire of the Local Authority to adopt the Birches system of sewage disposal, was well discussed, and eventually a deputation, consisting of Messrs. W. H. Key, W. Young, T. Salt, and G. Gilliver, was appointed to visit and inspect the sewage works at Birstall, Yorkshire, where the Birches system has been in operation for about three years. Mr. W. Battersby, a member of the Sanitary Authority, who had previously reported on a visit to the works in question, will accompany the deputation.

A LOCAL Government Board inquiry has been held at Caerphilly with reference to the proposed scheme of the Urban District Council for the drainage of Caerphilly, Llanbradach, Aber, and Senghenydd, in respect of which it was proposed to borrow £36,000. The district proposed to be drained under this scheme is about 17,000 acres, and the scheme is in two sections, viz, the Rhymney Valley and the Aber Valley. Future requirements were looked to in the arrangement of the scheme. Both mains would fall into a farm called Gwain-y-Bara, in the hamlet of Van, about a mile from Rudry. This farm had been purchased under a Provisional Order, and the sewage disposal scheme adopted was the intermittent and broad irrigation system. The present state of affairs in the four centres proposed to be drained was very serious. At Llanbradach and Caerphilly and in the Aber Valley houses were drained into cesspools, and the whole was eventually drained into the Aber Stream and Rhymney River, causing most serious and scandalous pollution. The Council had passed plans for over 2000 houses to be built in about two years, and the new colliery districts were increasing month by month, so that the Council felt it was a necessity to adopt some such scheme as would cope with the future development of the various centres in the districts.

ON Friday, May 13th, Major-General H. D. Crozier, R.E., an Inspector of the Local Government Board, attended at the Hampton District Council offices to inquire into the application of the Council for power to borrow the sum of £6000 for purposes of sewerage and sewage disposal. The Surveyor showed how the amount was made up, viz., by an additional ejector station, and various works connected therewith. The additional ejector was rendered necessary on account of the difficulty of making a sewer from three houses on the Hampton Court-road, where the large mains of the water companies would necessitate the sewers being laid at a great depth. In the course of the inquiry, which lasted nearly three hours, and in which the minutest details were entered into, the Inspector said it seemed to him that the Committee with a very light heart spent £6000 more than their estimate. In his opinion a fuller explanation was necessary before official sanction was given. Mr. Kemp said he had not prepared the estimate, and it was a very difficult district to estimate for. The Inspector said there was then all the more reason why an amount for contingencies should have been included. He was quite tired of these excesses of estimates in various parts of the country. He considered that Mr. Shone, who was largely responsible for the scheme, ought to have been present.

Lighting.

THE Urban District Council of Prestwich has decided to advertise its intention to apply for a Provisional Order for the electric lighting of the district.

IT is under contemplation by the Director-General of Telegraphs to apply to the Government of India for sanction to appoint an Inspector of Electricity for the city of Madras.

THE Ossett Town Council has decided to visit and inspect the electric lighting plant and refuse destructor at Shoreditch, with a view to ascertaining the practicability of combining the two objects in Ossett.

THE St. Annes-on-Sea Gas Bill, which had already passed the Commons, has gone through a Committee of the Lords unopposed. The Bill provides for the incorporation of the gas company with a capital of £45,000.

AT a recent meeting of the Gas Committee of the Aberdeen Town Council tenders for laying an electric cable for the harbour and west end of the city were opened. The offer of Messrs. Siemens Brothers, amounting to £12,138, was accepted.

THE Hampstead Vestry has just completed the electric lighting by arc lamps of Haverstock-hill and High-street, Hampstead, and as the St. Pancras Vestry has also completed its installation from Oxford-street to Haverstock-hill, there is now an unbroken line of public municipal lamps from Oxford-street to Heath-street, Hampstead.

THE Waterloo District Council has sealed the contract with Messrs. Wareing and Gillow, Limited, of Liverpool, for an electric light installation at the Town Hall.

THE Town Council of Port Glasgow has agreed to accept the offer of Messrs. Hanna, Donald, and Wilson for the extension of the gasworks. The work is estimated to cost over £1000.

AT a recent meeting of the Buckie Police Commissioners it was recommended by the Gas Committee that the Commissioners light the burgh of Portsoy with acetylene gas. This resolution was adopted. Portsoy is the first place in Scotland to adopt the new light.

THE Committee of Selection in the House of Lords has appointed the following peers to consider the Filey Water and Gas Bill among other private Bills. The Earl of Kintore (chairman), Lord Zouche of Haryngworth, Lord de Mauley, Lord Wolverton, and the Earl of Normanton.

THE negotiations between the General Purposes Committee of the Birmingham City Council and the Birmingham Electric Supply Company for the purchase of the concern by the municipality have resulted in a provisional agreement to be submitted to the Council and the company's shareholders. The terms are on the basis of £10 10s. per £5 share, which represents about their Stock Exchange value on the basis of the 5 per cent. dividend paid last year. The authorised capital of the company is £200,000 in £5 shares, and at the last valuation the total assets were set down at £244,504. Among the public buildings supplied by the company with electric light are the Market Hall, the Town Hall, the Victoria Courts, and the new General Hospital.

THE ordinary general meeting of the Bombay Gas Company, Limited, was held recently at the Offices, Drapers' Gardens. Mr. Robert Davidson presided, and in moving the adoption of the report, stated that throughout 1897 all the public lamps were lighted on the incandescent system, and had given the greatest satisfaction to the municipality and the public. There had been a diminution in the receipts from public lighting in the year amounting to £5015, and the falling off in the receipts from private lighting had been £3834. In the latter part of the year, however, the company was making progress in regard to the private lighting. They had anticipated a decrease in the revenue from public lighting, owing to the cost of maintaining the Welsbach mantles, but they had also expected an increase in the private lighting, and had hoped that the one would meet the other. That, however, had not been the case in consequence of the continued prevalence of the plague, which had disastrously affected the condition and industries of Bombay, causing a considerable falling off in the consumption of gas for private consumers. They proposed to pay a further dividend of 3 per cent., making 6 per cent. for the year, and to do this they had taken £1255 from the reserve fund, which had been accumulating for many years. The motion was seconded and adopted.

THE Tottenham Urban District Council has received a communication from the Local Government Board stating that, owing to varying opinions on the subject of the danger accruing from the manufacture and supply of water gas, a departmental inquiry was to be held, and this Council was asked to send a representative to afford any information on the subjec possible.

AT a recent meeting of the Electric Lighting Committee of the City Corporation of Leeds, the Chairman (Mr. Skinner) submitted the statement of the working of the installation in the city during the past year. The Committee commenced the year just ended with the carrying out of a large extension of the electric system to the west and north of the port, estimated to cost £40,690. These works were now well in hand, the buildings were near completion, and the equipment was being carried on with despatch. The total expenditure on capital account was now £61,738, of which £14,153 had been spent during the year. The total revenue was £10,453; expenditure, £5450; balance, £5003. The interest on loans amounted to £1496; contributions to sinking fund, £1467; leaving a net profit on the year's working, £2040. The increasing demands being made for current, even at this season of the year, and the pledge made to the residents in East Hull, rendered it necessary that the Committee should take in hand very shortly a further extension. The report, which was considered very satisfactory, was unanimously adopted.

THE Special Sub-committee of the Birkenhead Gas, Water, and Electrical Committee, appointed to report upon the manufacture and supply of carburetted water gas by the Corporation, now report that investigations have been made by the borough gas engineer, Mr. T. O. Paterson, M. Inst. C.E., with the result that of the 241 persons who petitioned the Council, complaining of badly-lighted houses and streets, and noxious smells, and alleging serious injury to health from the gas supply, 177 replied to a circular requesting a definite complaint. In 129 cases a special inspection was made, and in 38 cases the defect was remedied, 51 were satisfied without anything being done, and 30 persons remain dissatisfied. Statistics are given showing that the average illuminating power of the gas during the year was higher than the preceding four years, when water gas was not mixed with the coal gas. The report also states that the number of complaints fell from 3914 in 1896 to 1539 last year, and police complaints of street lamps were likewise reduced in a marked degree, while the utter absence now of naphthaline deposits in the services has removed a fruitful cause of complaint. As to the bad smells alleged, the Committee state that every precaution is taken to prevent the emission of bad smells at the works, and quote from a special report by Sir Henry Roscoe, "The products of combustion of carburetted water gas are not more injurious to health than are those of coal gas;" and a somewhat similar opinion given by Professor Lewis, F.I.C. If the same care and attention were paid to pipes and fittings as has been given when coal gas only was supplied, there can be no reasonable or valid objection to the supply and use of their new gas.

Notes and Queries.

Subscribers have the privilege of obtaining advice in this column on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed to THE EDITOR, "Notes and Queries," THE SANITARY RECORD, 5, Fetter-lane, London, E.C.

NOTE.—If an answer be required immediately, a stamped addressed envelope must be enclosed, when we will endeavour to furnish a copy of the answer by post, as owing to the large number of queries received we cannot guarantee the insertion of a reply in the succeeding issue.

1079. — FORMALIN DISINFECTANT FOR ROOMS.—"Sanitas Sanitatum" writes:—"May I trouble you for information as to the disinfectant called 'Formalin,' as to its chemical characteristics, mode of manufacture, and effects?"

Answer.—The disinfectant "Formalin" is a powerful one, and is described as a preservative and deodorising liquid of 40 per cent. Formic Aldehyde. Technically, an aldehyde is an alcohol de-hydrogenated, and, as a rule, an alcohol is transformed into aldehyde when it loses two atoms of its hydrogen. Thus, wood spirit (methyl alcohol) (CH_3OH), when deprived of H_2, becomes CHOH, called formic aldehyde, because it very readily changes to formic acid (CHOOH). The aldehyde vapours are irritating to the eyes and throat, and are a most effective disinfectant for the surface disinfection of rooms. Dr. Kenwood, Assistant-Professor of Public Health, University College, London, who has carried out numerous experiments to test its efficacy, states that the following conclusions are amply warranted:—(1) That when the atmosphere is charged with less than 1 per cent. of the vapour, the disinfection of all surfaces is complete and rapid. (2) That the vapours possess a certain and variable amount of penetrating power into loose fabrics, especially when these are dry. (This has been proved by numerous independent workers). (3) That the vapours do not affect the colours of textile materials nor (with the exception of iron or steel) metallic surfaces. (4) That the rooms and articles exposed can be cleared of the vapours readily by sufficient aëration, and the vapours are not so irritating, but one can always enter the room and unseal at the first attempt. (5) That the disinfecting properties of the aldehyde are greater than those of sulphurous acid or chlorine. (6) That there is no danger in entering the room, either from the aldehyde or from the CO, which is formed at the same time. The aldehyde is generated by a lamp, specially devised for the purpose, illustrations of which are furnished by the patentees, the Formalin Hygienic Company, Ltd., 9 and 10, St. Mary-at-Hill, London, E.C. Our correspondent should obtain Dr. Rideal's excellent book, "Disinfection and Disinfectants," price 12s. 6d. (or if subscription copy is obtained, 10s.), as to which see advertisement in our pages.

1080.—NUMBERING HOUSES AND NAMING STREETS IN RURAL DISTRICTS.—"J. G." writes:—"In several of the larger villages in this rural sanitary district considerable inconvenience is caused by reason of the houses not being numbered, nor the streets named. What steps can be taken by the Rural Council to obtain powers to do the work?"

Answer.—By Section 25 (5) of the Local Government Act, 1894, Rural District Councils are to have such powers, duties, and liabilities of Urban Sanitary Authorities under the Public Health Acts, as the Local Government Board may by order direct. Sec. 160 of the Public Health Act, 1875, confers upon Urban Authorities the power to name streets and number houses, as prescribed by Secs. 54 and 55 of the Towns Improvement Clauses Act, 1847. The Authority may cause to be put up or painted on a conspicuous part of any house, building, or place near or at the end of every street, the name by which such street is to be known, and they may require the occupiers of houses to mark their houses with such numbers as the Authority approve of, and to renew them as often as they become obliterated or defaced.

1081.—DISINFECTANT FOR FLUSHING DRAINS.—"F. W. S." writes:—"I am about to engage a man to daily disinfect the drains of houses where infectious disease exists. Will you please tell me the best disinfectant for the purpose? I had thought of perchloride of mercury. If that, what is the best mixture to make?"

Answer.—We are of opinion that good results will be obtained by using almost any disinfectant if manufactured by a firm of repute. A reference to our advertising pages will give the names of some reliable firms; and if their instructions be followed as to the method and proportions of the mixture, which should be obtained from them, satisfactory results may with confidence be apprehended. If it be desired to use perchloride of mercury (corrosive sublimate), we should advise that it be obtained in block form, as manufactured by the St. Bede Chemical Company, Limited, Newcastle-on-Tyne. This company make it up in small blocks, costing about 3d. each, which are dissolved in either hot or cold water, and which give about one quart of strong disinfectant. In this form it is convenient and safer to use than is otherwise the case.

1082.—FOOTPATH: STILE DEFECTIVE.—"Surveyor" writes:—"In a parish in a rural district there is a stile across a footpath which is in a bad state of repair and dangerous for foot-passengers. Notices have been served on the owner and occupier to repair it, but neither of them take any notice. Will you please advise what steps we can take in the matter?"

Answer.—If a person while passing over the stile were to receive an injury owing to the dangerous condition or non-repair of the said stile, the person whose duty it is to repair the stile would be liable. The District Council as the Highway Authority may remove the stile or institute proceedings against the occupier as for a nuisance. The Parish Council may, however, undertake its repair and maintenance under Sec. 13, Sub.-sec. 2, of the Local Government Act, 1894.

1083. — DISINFECTANT FOR STREET WATERING RECOMMENDED.—"Surveyor" writes:—"It is desired to use a disinfectant which may be mixed with the water in the street-watering vans so as to disinfect the roads and streets, which is, it is considered, a sanitary measure, and carried out in many towns. Will you please advise me as to the most convenient method in which the disinfectant may be applied?"

Answer.—We are informed by those who have practical experience in the superintendence of street watering that the disinfectants described as Carberzone and Pynerzone, and manufactured by Messrs. Hope and Sons, Oaklane Chemical Works, Limehouse, London, E., are probably the most convenient and popular disinfectants in use for street watering. They are both put up in the form of soluble blocks, weighing about 3 lb. each. One of the blocks is placed in the watering van, and gradually dissolving, is sufficient to disinfect about eighteen van loads of water, and will last a whole day. Pynerzone is claimed to be a complete disinfectant, being an extract of pine, eucalyptus, and purified thymol; and Carberzone is an extract of carbolic acid, cresylic acid, and naphthaline. A result of using these disinfectants is that a very agreeable, fresh, and healthy odour is given to the atmosphere of the streets. The blocks are comparatively inexpensive, twenty-five of them costing about £1 15s. This system of disinfecting the roads is a commendable one.

1084.—CONSTRUCTING NEW BAY WINDOW: CONSENT OF URBAN AUTHORITY NECESSARY.—"G. H." writes:—

"Can the owner of a building bring out a bay window beyond the front main wall of his house without obtaining the consent of the Urban Authority?"

Answer.—No. By Sec. 3 of the Public Health (Buildings in Streets) Act, 1888, it is enacted that "it shall not be lawful in any urban district without the written consent of the Urban Authority to erect or bring forward any house or building in any street, or any part of such house or building, beyond the front main wall of the house or building on either side thereof in the same street, nor to build any addition to any house or building beyond the front main wall of the house or building on either side of the same." The erection of a bay window under the circumstances named by our correspondent would render the offender liable to the penalties prescribed by the Act.

1085.—SHOP HOURS ACT INSPECTORS: DUTIES OF.—"R. C. U." writes:—"Will you kindly inform me what are the duties of an Inspector appointed under the Shop Hours Act? Also if you know of any book having reference to such duties?"

Answer.—We answered a similar query (No. 1018) in our issue of April 1st, to which our correspondent should refer.

1086.—NUISANCE FROM DRAIN: PROCEDURE.—"C. G." writes:—"A. has a drain passing under the kitchen of another house belonging to a different owner, B. The drain was constructed before the kitchen was erected. A nuisance now arises in the basement of B.'s house, owing to moisture soaking through the walls, presumably from the drain. The probabilities are that B. has, during some repairs, choked the drain at the farther end of his premises. B. now lays a complaint against A. We have no system of sewerage, neither have we any bye-laws. I have served a notice on B. to abate the nuisance on his premises, but he refuses to do so. Do you think I should have any difficulty in getting an order made on B. to abate the nuisance?"

Answer.—We should advise our correspondent to get more definitely at the facts of the case. It is not sufficient to presume that the moisture arises from A.'s drain, or *conjecture* that the drain is blocked. It would be useless to go before a court of summary jurisdiction for an order with such evidence. The Inspector of Nuisances must proceed under Sec. 41 of the Public Health Act, 1875, and obtain the authority of his Council to enter the premises whereon the alleged nuisance exists, open the ground, and examine the drain; and if the drain appears to be in bad condition, the Local Authority, as prescribed by the section, should forthwith give notice to the owner, B., of the premises, to do the necessary work of repair or relaying. We presume that the drain receives the drainage of one house only. If it be otherwise, and receives the drainage of two or more houses, it may be a sewer vested in and repairable by the Local Authority. We do not know what our correspondent means by stating that they have no system of sewerage and no bye-laws. The absence of either of these does not affect the question.

1087.—BUILDING BYE-LAWS: ERECTION OF NEW BUILDING.—"W. C. C." writes:—"I beg to thank you for your reply to Query 1077, and now send you the plan as requested, also copy of Building Bye-laws."

Answer.—It is provided by Bye-law 55 of this Council's Bye-laws that every person who shall erect a new domestic building shall provide in front of such building an open space, which measured to the boundary of any lands or premises immediately opposite or to the opposite side of any street which such building may front, shall throughout the whole line of frontage of such building extend to a distance of 24ft. at the least. From the plan submitted to us it appears that the distance from the front of the proposed club-room to the opposite side of the street on which it abuts is only 15ft. If the proposed club-room can be held to be a domestic building, it therefore follows that its erection as proposed would be a contravention of the Bye-laws. But on referring to Clause 1 of the Bye-laws for an interpretation of the term "domestic building," we find the term "domestic building" defined as "a dwelling-house, or an office, building, or other out-building appurtenant to a dwelling-house, whether attached thereto or not, or a shop or any other building not being a public building or of the warehouse class." We are of opinion that the proposed club-room cannot be held to be a domestic building, but that it falls within the definition of a "public building" which is interpreted in Clause 1. There may, however, be some circumstances in connection with the proposed club-room which may bring it within the definition of a "domestic building," such as the use of any part of it for the purposes of a dwelling-house for a caretaker, and if so the bye-law will apply. If, however, the circumstances do not show that the building can be held to be a "domestic building," the Local Authority should consider whether the owner is not commencing to lay out a new street, and if such be the case, he should be required to set back 18ft. from the centre of the existing road, as the bye-laws require new streets to be of a width of 36ft. For it has been held over and over again that an old road may become a new street by the erection of houses alongside it. See Robinson *v.* Barton Local Board, 48 J.P. 276, &c. &c. We think the Local Authority would be justified in requiring the proposed building and the street widened, in so far as the building must be set back 18ft. from the centre of the existing road.

ANTISEPTIC

DISINFECTANT. **DEODORANT.**

INODOROUS **DISINFECTION.**

Absolutely Non-Poisonous, Non-Corrosive, Non-Volatile, and does not Stain.

See published Bacteriological Report by Dr. E. KLEIN, St. Bartholomew's Hospital, London.

CHINOSOL SANITARY TABLETS are the most convenient, most effective, and most economic for the immediate production of Disinfecting Fluids. **12 Tablets**, packed in one tin to carry in waistcoat pocket, price **2s.** One Tablet in warm or cold water produces in **less than one minute**:—

3 Quarts of a strong Deodorant and Disinfectant, sufficient to spray one infected room of 1000 cubic feet; or

3 Gallons of a strong Disinfectant for flushing drains, walls, floors, &c.

Literature (Dr. Klein's Report) and Samples free to the Profession.

Contracts Open.

The dates given below are the latest up to which tenders can be received.

HUNSLET (LEEDS).—May 21st.—Scavenging.—Mr. W. B. Pindar, clerk, Leek-street, Hunslet.

SALE.—May 21st.—Draining.—The Cemetery Committee, 4, School-road, Sale.

ALNWICK.—May 23rd.—Cleaning out, &c., Sewage Ditch.—Mr. H. W. Walton, Alnwick.

CLAYTON-LE-MOORS (LANCS.).—May 23rd.—Sewer, &c.—Mr. Arthur Dodgeon, surveyor.

BANGOR (IRELAND). — May 24th. — Sewer. — The Town Commissioner's Office.

KNUTSFORD. — May 24th. — Sewage Works. — Mr. Walter J. Downs, surveyor, Knutsford.

PONTEFRACT.—May 24th.—Sewers.—Mr. A. Oddy, borough surveyor, Town Hall, Pontefract.

GREENWICH.—May 25th.—Sewer.—The offices of the Board, 141, Greenwich-road, Greenwich.

WEST ARDSLEY (YORKS).—May 25th–June 3rd.—Sewers.—Mr. Frank Massie, A.M.I.C.E., Tetley House, Kirkgate.

WIGAN. — May 25th. — Scavenging. — Mr. Henry Ackerley, 9, Victoria-buildings, King-street, Wigan.

HULL.—May 26th.—Nightsoil Collection.—Inspector of Nuisances, Lowgate.

TURTON (LANCS).—May 26th.—Sewage Purification Works.—Mr. V. W. Laithwaite, surveyor to the Council, Public Offices, Bromley Cross, near Bolton.

WESTHOUGHTON (LANCS).—May 23rd.—Sewers.—Mr. Thos. Partington, clerk and surveyor.

BURY ST. EDMUNDS.—June 13th.—Plant.—Mr. F. Hastings Medhurst, B.Sc., M.I.E.E., consulting engineer to the Corporation, Westminster-chambers, 13, Victoria-street, S.W.

Vacancies.

ASSISTANT ENGINEER, &c. (WATERFORD, May 26th).—For the Public Health Committee. Salary £4 a week. Mr. James J. Feely, town clerk, Waterford.

BUILDING FOREMAN (WALTHAMSTOW, May 27th).—For the Urban District Council. Salary £3 10s. per week. Mr. E. J. Gowen, clerk, Town Hall, Walthamstow.

CLERK OF WORKS (BRISTOL, May 20th).—For the Bristol School Board. Remuneration £3 3s. per week. Mr. Wm. Avery Adams, clerk, Guildhall, Bristol.

CLERK OF WORKS (TRING, HERTS, June 4th).—For the Urban District Council. Salary £3 3s. per week. Mr. A. W. Vaisey, clerk, Council Offices, Tring.

REYNOLDS & BRANSON, 14, Commercial Street, LEEDS.

CITY ENGINEER (CAPE TOWN, June 15th).—For the Corporation of the City of Cape Town. Commencing salary £800 per annum. Messrs. Davis and Soper, 54, St. Mary-axe, London, E.C.

DRAUGHTSMAN (May 23rd).—Salary £3 3s. per week. H. H., care of Brown's, 17, Tothill-street, Westminster, S.W.

DEPUTY CITY SURVEYOR (CARLISLE, May 23rd).—For the Corporation. Salary £150 per annum, rising by annual increments of £10 to a maximum of £200 per annum. Mr. Henry C. Marks, A.M.I.C.E., city surveyor, 36, Fisher-street, Carlisle.

ENGINEER, &c. (HARTLEPOOL, May 24th).—For the Hartlepool Port and Harbour Commissioners. Salary £400 per annum. Mr. S. Herbert Belk, law clerk to the Commissioners, West Hartlepool.

ENGINEER AND SURVEYOR (SUTTON COLDFIELD, May 23rd).—For the Corporation. Salary £300 per annum. Mr. Thos. V. Holbeche, town clerk, Sutton Coldfield.

HIGHWAYS SURVEYOR (HAVERFORDWEST, May 24th).—For the Rural District Council. Salary, £110 per annum. Mr. John James, clerk, Haverfordwest.

SANITARY INSPECTOR (LONDON, S.E., June 2nd.—For the Vestry of Lambeth. Salary, £120, rising £5 yearly to £170. Application forms to be obtained at the Vestry Hall, and sent to Mr. Henry J. Smith, clerk, Lambeth Vestry Hall, Kennington Green, S.E.

SANITARY INSPECTOR (WARWICK, June 4th).—For the Town Council. Mr. Brabazon Campbell, town clerk, Jury-street, Warwick. The inclusive salary will be £62 per annum.

SURVEYOR (BEXLEY, May 25th).—For the Urban District Council. Salary, £200 per annum. Mr. Thos. G. Baines, clerk, Council Offices, Bexley Heath.

SURVEYOR (THAKEHAM, May 20th).—For the Rural District Council. Salary £100 per annum. Mr. Herbert Parsons, clerk, Storrington, Sussex.

WATER INSPECTOR (LLANDUDNO, May 28th).—For the Urban District Council. Wages, 30s. weekly. Mr. E. Paley Stephenson, A.M.I.C.E, engineer, Council Offices, Llandudno.

COMPETITIONS.

FORMBY (LANCS), July 1st.—Sewerage Scheme.—The Formby Parochial Committee invite competitive schemes for the sewerage of a portion of the township of Formby. Premiums are offered amounting to £100 for the scheme considered first in order of merit, £50 for the second, and £25 for the third. Mr. J. H. Havelock Sutton, Piercefield-road, Formby. A professional assessor will be appointed to adjudicate upon the plans.

To Medical Officers, Surveyors, Sanitary Inspectors, &c.—High-grade Cycles at reasonable prices for prompt cash and on the GRADUAL PAYMENT SYSTEM. Catalogue post free.—MELROSE CYCLE COMPANY, Coventry.

SANITARY ASSOCIATION OF SCOTLAND.

EXAMINATIONS IN SANITARY SCIENCE.

Examinations for Certificates of Competency in Sanitary Science are held each year as follows, viz.:—In Glasgow in April, in Edinburgh in October, and at such other time and place as the Board of Examiners may determine.

Entrance Fee £2 2s.

For further particulars apply to

GEORGE MIDDLETON, M.A., LL.B.,
Writer, 92, Bath Street, Glasgow,
Secretary to the Board of Examiners.

A Stamped Addressed Envelope must accompany all letters requiring an answer.

SANITARY INSTITUTE EXAMINATIONS.

TUITION BY CORRESPONDENCE.

An Engineer and Surveyor (Mem. San. Inst.), Certificated Surveyor and Inspector, prepares students for these Exams. by Correspondence through the post.

Fees strictly moderate. Cramming studiously avoided.

The course of tuition is arranged so as not only to qualify the student for passing the exams., but what is of equal importance, viz., that he may become a thoroughly efficient Inspector.

On successfully passing the exams., all possible assistance and advice is given to help forward intending candidates for public offices.

Many of my old pupils are now filling positions with salaries of over £120 a year.

For terms, &c., address "C. E.," care SANITARY RECORD, 5. Fetter-lane, London, E.C.

OFFICIAL ADVERTISEMENTS.

THAKEHAM RURAL DISTRICT.

INSPECTOR OF NUISANCES.

The Rural District Council of Thakeham are prepared to receive APPLICATIONS for the appointment of an INSPECTOR of NUISANCES for the whole of their District, which comprises an area of 40,635 acres, with a population of about 8100.

The appointment is an annual one, and the salary, subject to the approval of the Local Government Board, will be £70 per annum, to include all travelling expenses.

The person appointed will be required to commence his duties at Midsummer-day next, or as soon thereafter as possible.

Candidates must hold the certificate of the Sanitary Institute.

Application, which must be in the handwriting of the candidate, and state age and present and previous occupation, and which may be accompanied by copies of not more than three testimonials, must be sent (endorsed "Inspector"), addressed to "The Clerk to the R.D. Council of Thakeham," at the undermentioned address, so as to be received not later than Saturday, the 28th instant.

Any candidate canvassing any member of the Council, whether personally or by letter, will be disqualified.

By order of the Council,
HERBERT PARSONS,
Clerk to the Council.

Clerk's Office, Storrington, Sussex,
May 11th, 1898.

Silver Medal. Edinburgh, 1889. Gold Medal. Jamaica, 1891. Gold Medal, Derby, 1891. Highest Award at Chicago Exhibition. Altogether Six Gold Medals received.

COLEMAN'S WINCARNIS

Is a delicious beverage and tonic made from Port Wine, Liebig's Extract of Meat, and Extract of Malt.

WINCARNIS is a name registered to prevent fraudulent imitations.

OVER FIVE THOUSAND

Unsolicited Testimonials have been received from Medical Men.

The following Important Testimonial has been received from Dr. FLETCHER.

Applecross, Rosshire, N.B, July 2nd, 1897.

Dear Sirs,—Please forward quarter-of-a-dozen "Wincarnis" immediately, as my patient's supply is about done.

I trust there will be no delay, as he takes no other nourishment, and has been sustained and gained strength by "Wincarnis" for twelve weeks.—Yours faithfully, DUNCAN FLETCHER, L.R.C.P.

WINCARNIS is sold by all Druggists, Wine Merchants and Patent Medicine Vendors. Ask for Coleman's "Wincarnis," and see that the word "Wincarnis" is on the shoulder of the bottle. Sold in bottle, 2s 9d & 4s. 6d. everywhere.

Sole Proprietors and Manufacturers of the above,

The New Prison Rules.

To those who believe that prison treatment should have for its object the working of a true reform in the character of criminals, the proposed new prison rules will give considerable satisfaction. On Friday last the Home Secretary caused copies of two drafts to be distributed to the members of the Grand Committee on Law. In one of these local prisons are dealt with, and the other refers to convict establishments. The harsh treatment hitherto prevailing in the case of prisoners awaiting trial is to be modified. "Searching" is to be carried out with "due regard to decency and self-respect." In penal servitude

cases the use of the plank-bed is to be practically discontinued, except as punishment for incorrigibles. Physical and mental weakness is not to prevent the giving of marks by which a partial remission of the sentence may be obtained. Unproductive labour—"the mill" and "the crank"—are to be abolished. Women are to be put to such work as may be of use to them when their term of punishment ceases; and illiterate prisoners are to have schooling at least two days per week. Outdoor exercise is to be given with greater regularity than in the past, for where hitherto it has not been possible to grant this on wet days, covered walks are to be provided. Other rules refer to granting the use of books from the prison library; the modification of the "silent" system, letter writing, &c. The consideration of these proposed rules by the Grand Committee is postponed until after the Whitsuntide recess.

Sewage Bacteriology at the Chemical Society.

The paper recently read by Messrs. Dibdin and Thudicum before the Chemical Society continues to excite the interest of all engaged in watching the development of the latest experiments in sewage treatment. That bacteriological methods are successful in comparatively small systems has long been demonstrated beyond disproof; yet many have expressed doubts as to their power to successfully meet the requirements of large manufacturing towns and cities. But even these doubts are now set at rest, for, as the writers of the paper showed, the trial bacteria bed at Knostrop has more than accomplished what it was expected to. Over 200,000 gallons of sewage from Leeds (which included the waste products from copper precipitation and galvanising works, tanneries, and any amount of shoddy waste) daily pass through the coke filters, the effluent therefrom being so pure that fish live in it. At Maidstone, with its numerous breweries, and West Bromwich, with "waste pickle liquors from galvanising works," similar satisfactory results have been obtained, thus conclusively proving that, even under the most trying conditions, the "truly scientific system" surpasses all others in its efficacy and efficiency. The publication of this paper is exceedingly opportune, and the facts therein related will no doubt provide excellent evidence for the recently-appointed Royal Commission.

A Woman Inspector for the Potteries.

It is hard to break through the prejudices and practices of a great Government Department. For years the Home-office fought against the appointment of women to inspectorships of any kind, and to-day it is equally zealous in contesting any suggestions for further departures from the administrative path it has itself marked out. Take, for instance, the reply given by the Home Secretary to the deputation which waited on him last week, asking for the appointment of a woman Inspector for the Potteries district. The facts brought forward showed there was an average—according to Government returns—of 400 deaths every year from lead poisoning, most of the victims being women and young people. In addition cases of blindness were numerous in the particular district known as the "Potteries." It is stated that upwards of 20,000 women are employed in the "potting" industry. For this reason it was urged that a woman Inspector should be appointed to inquire and report where so large a number of women and young children were employed in what was admitted to be a dangerous trade. The Home Secretary in the course of his reply admitted the truth of the facts put forth; and said experts were at present in the district making inquiries into the effect of certain glazes and pigments upon the workers. New rules were also being printed enforcing the periodical inspection of women and children, and the provision of better arrangements for washing and for taking meals. But he could not consent to this inspection being carried out by "a special lady Inspector," because he thought that touched "a difficult administrative question." Are decency and humanity to be sacrificed for "red-tape"? The time for such antiquated ideas has long since passed away. If the inspection of women is to be carried out, for common decency's sake let a woman be appointed to do it. The members of the deputation who are members of Parliament must bring the question before the House of Commons, and ask it to do what the Home-office declines. We are sure the country will support them in their demand.

The Responsibility of Employers.

An important judgment was recently delivered in the Court of Queen's Bench as to the responsibility of employers for the conduct of their servants. The case arose out of the Merchandise Marks Act, 1887. A shop assistant had sold a ham as "Scotch," but which in reality was of foreign origin. A summons was taken out against the firm, and the borough magistrates convicted. A case was ordered to be stated, and it was argued before Mr. Justice Wright and Mr. Justice Darling, who sustained the decision of the bench. But the firm was not satisfied, and appealed to the Queen's Bench. A long judgment was given by the Lord Chief Justice, in which he carefully analysed the case in all its bearings. Concluding, he said, "The appellant carries on an extensive business as grocer and provision dealer, having, it appears, six shops or branch establishments, and having also a wholesale warehouse. It is obvious that if sales with false trade descriptions could be carried out in these establishments with impunity so far as the principal is concerned, the Act would, to a large extent, be nugatory. I conceive the effect of the Act to be to make the master or principal liable criminally (as he is already by law civilly) for the acts of his agents and servants in all cases within the sections with which we are dealing, where the conduct constituting the offence was pursued by such servants and agents within the scope or in the course of their employment, subject to this—that the master or principal may be relieved from criminal responsibility, where he can prove that he had acted in good faith and had done all that was reasonably possible to do to prevent the commission by his agents and servants of offences against the Act. The result therefore is that the conviction will be affirmed, and with costs." If the judgment had

been otherwise, it would have made it almost impossible for Food and similar Inspectors to have obtained convictions—at any rate, of the really responsible parties.

Edward Bellamy.

Few books of a socialistic character have created more interest than "Looking Backward," the production of Edward Bellamy, who died on Sunday last in his home at Chicopsee Falls, Massachusetts. Mr. Bellamy wrote other books, but the one we have named made him famous. In the form of a dream he endeavoured to depict what the world would be a hundred years hence. Those who have read the work will recollect the vast improvements he predicted would be experienced in the hygienic conditions in which men would be living. To some, much that he wrote may appear nothing more than the fancies of an idealist; but, judging by comparisons, his predictions may prove much nearer truth than we at present imagine. Think of the condition of the world at the commencement of the present century; then count up what has been discovered and invented in the intervening years, and the transformation to-day is no less marvellous than anything set forth in "Looking Backward." Edward Bellamy may have been a "dreamer;" but such men by their parables inspire their fellows to noble thoughts and grand accomplishments, and the hope for better days and happier conditions gives zest to the endeavour to win them; if not for themselves, for their children.

Municipal and County Engineers.

Not the least important feature in connection with the work of the Incorporated Association of Municipal and County Engineers is the holding of district meetings in various important centres. Many are able to attend these gatherings who, for obvious reasons, are prevented from taking part in the larger or national meetings. A few weeks ago we reported the proceedings of one of these meetings at Wimbledon, and we now have before us the programme of another, viz., the Yorkshire district meeting, which is to be held at Harrogate on Saturday, June 4th. The formal business of the meeting will be the election of a district secretary. The attraction to many, however, will be the visit to the Gouthwaite Compensation Reservoir. The members are to meet at Harrogate station at 9 o'clock, travelling from there to Pateley Bridge Station, where brakes will be in waiting to convey them to the reservoir, about three miles from the station. Every facility will be given for a thorough inspection of the works, which possess many features of special interest. At noon light refreshments will be provided by the Waterworks Committee, and at 5.30 the same Committee will entertain the visitors to dinner at the King's Arms Hotel. Members intending to be present should at once send on their names to Hon. District Secretary, T. W. Stainthorpe, A.M.I.C.E., Council Offices, Grangetown, Yorks.

Nuisances by Noise.

There are no provisions in the Public Health Act, 1875, which bring nuisances by noise within the purview of Local Authorities who have to administer the Act. Such could only be removed by an action at common law, by a private individual who suffered from their continuance With regard to most nuisances of this character, such as those from engines, factories, &c., redress will continue to be obtainable only by a private action. In the case, however, of nuisances by noise, such as from playing instruments, &c., to the annoyance of the inmate of any house, we think the decision of the High Court on the 14th inst., in Kruse *v.* Johnson, will have a most important effect. The case was an appeal from the Justices of the Bearsted Division of the county of Kent, raising the question of whether a bye-law made by the County Council of Kent was valid, and was stated in the Queen's Bench Division before the Lord Chief Justice of England and numerous other judges. The facts of the case were that the appellant on October 17th, 1897, persisted in singing in a public highway within fifty yards of a dwelling-house after having been required by a constable to desist, and that he was, on the occasion in question, conducting an open-air religious service, and that in so doing he contravened one of the bye-laws of the County Council, which was as follows:—"Playing musical instruments. No person shall sound or play upon any musical or noisy instrument or sing in any public place or highway within fifty yards of any dwelling-house after being requested by any constable or by any inmate of such house personally or by his or her servant to desist," &c. On behalf of the appellant it was contended that the bye-law was *ultra vires* on the ground that it was unreasonable, and therefore bad. The bye-law was made in pursuance of powers conferred on the County Council by Sec. 16 of the Local Government Act, 1888. The Lord Chief Justice delivered a lengthy judgment, in which all the other judges—with the exception of Mr. Justice Mathew—concurred, and was, shortly, to the effect that the bye-law in question was reasonable and valid, and that the appellant was rightly convicted. The result of this decision will be, we predict, that other County Councils will follow the example of the Kent County Council, and adopt bye-laws of a similar purport to restrict nuisances by noise of the character described in the Kent County Council bye-law.

Lady Cyclists and Publicans.

According to our esteemed contemporary *Justice of the Peace*, it would appear that a publican who refuses to admit lady cyclists in "rational dress" as guests in his coffee-room is, it is believed, acting within his legal rights. Under the Licensing Acts a publican, it seems, has a right to turn out persons who are drunken, violent, quarrelsome, or disorderly, or whose presence on his premises would subject him to a penalty. He may also, it is stated, at common law exclude persons whose presence might be reasonably objectionable to other guests in his house, as a chimney-sweep in his working attire, or a person accompanied by a large dog which causes alarm, and so it is deduced that a publican may legally exclude the lady in "bloomers" so long as such costume is reasonably objectionable to other guests. While we have very considerable respect for the opinions given by the legal editors of our contemporary, we venture to think it is very desirable that a "test case" should be taken

to determine whether a publican is to be allowed to exclude lady cyclists to suit his whims, for in the case referred to there does not appear to have been any evidence that the presence of the lady in rational dress was objectionable. If the representatives of John Barleycorn are to be permitted to exercise such extensive powers as to set themselves up to be judges of male and female attire the privileges of the public are likely to be considerably infringed.

The Suppression of Rabies.

The parliamentary return of proceedings under the Diseases of Animals Act during the past year, which has now been issued by the Board of Agriculture, contains much interesting information regarding the areas in England and Wales where muzzling orders are in force, and the districts where rabies has been prevalent, and other miscellaneous matters. But the chief element of interest in the report is that part of it which makes review of the past, and looks forward to the future. Mr. Alexander C. Cope, the Chief Veterinary Officer, says that "the returns for the year 1897 show such a satisfactory diminution in the number of cases in Great Britain as to encourage the hope that rabies, which has existed in this country from time immemorial, will be entirely eradicated." That is a most encouraging prospect, and fully justifies the policy of muzzling that has been so much attacked, on account of the discomfort it occasions to dogs. When the total extinction of rabies is an accomplished fact, we may then hope to do away with the necessity for muzzling orders.

Work at the Pasteur Institute.

From this interesting record of the successful results of the policy pursued by our own Board of Agriculture, it is instructive to turn to the annual report of the Pasteur Institute for 1897, which shows that of 1521 persons who underwent the preventive treatment at the Institute last year, six died, the mortality being at the rate of nearly ·40 per cent. The returns of the past eleven years, since the work of the Institute commenced, show that by far the largest number of cases was treated in the first year. In that year there were 2671 patients treated, and the rate of mortality was ·94 per cent. Since then the number of patients treated every year has fluctuated considerably, the lowest number being in 1896, when there were only 1308 cases. The mortality rate also underwent a steady decrease for a number of years. In 1892 it was only ·22 per cent., which is the lowest that has yet been attained; but since then it has been somewhat higher. From which it would appear that, while the Institute still continues to attract large numbers of patients from all parts of the world, its popularity has not been so marked during the past half-dozen years as it was during the earlier period of its existence.

The Sanitary Condition of Potato-diggers.

We are indebted to Dr. McVail, Medical Officer for the counties of Stirling and Dumbarton, for directing public attention to the lamentable condition of a class of the population of whose very existence note is seldom taken. We refer to the migratory class known as potato-diggers. They come for the most part from Ireland, scattering themselves over the face of the country in gangs, and moving from farm to farm as their services may be required. The character of the accommodation to which they are accustomed during their wanderings may be judged from the facts which Dr. McVail elicited regarding a particular gang in Stirlingshire, whose experience is stated to be by no means exceptional. The gang, of twenty-one men and women, were all lodged in a bothy, consisting of a single apartment, 17ft. square, without the faintest suggestion of any sanitary conveniences, the surroundings being, on the contrary, as insanitary as it is well possible to conceive. Small wonder that the Medical Officer should have declared that never before had he seen human beings lodged under conditions so utterly indefensible as regards both health and decency, and still less wonder that such a deplorable condition of affairs should have been followed by an outbreak of enteric fever. And yet the poor people were not sufficiently educated to be even discontented with their wretched surroundings. But what must we think of the farmers who have so little regard for the well-being of their employés as to suffer the continuance of such a state of things, allowing human beings to herd together like cattle, to the danger, not merely of their own health and lives, but also of those of the whole neighbourhood?

A Case of Ptomaine Poisoning.

Many of our readers will doubtless read with interest the report which appears elsewhere in our columns, of the action which was tried last week, before Mr. Justice Hawkins and a special jury, in the Queen's Bench Division, and in which damages were claimed from a firm of butchers for the sale of what was alleged to be unsound meat. The beef was cooked immediately after purchase, but was not consumed till a couple of days later, having in the interval been kept in the household meat safe. All the members of the family who partook of the meat were afterwards attacked by sickness, and they were all pronounced to be suffering from ptomaine poisoning. The plaintiff jumped to the conclusion that the meat must have been unsound when sold, and brought his action of damages against the butchers accordingly, but the facts which were brought to light, in the course of the evidence, put a very different complexion on the case. Briefly, the line of evidence was this—the meat safe was shown to be one which projected into the well of the tenement, and in the bottom of the well the refuse of the various tenants of the building was daily gathered for removal. It was also proved by the medical witnesses that the poisonous character of ptomaines is due to the agency of certain bacteria, which may be derived from various sources, and which may be developed after cooking in meat which was at first perfectly sound. Now the nature of the place where the meat was kept was one which was favourable to the development of such bacteria, and it was not, therefore, surprising that the jury should have inferred that the meat must have become unsound while in the plaintiff's possession, especially as it appeared that other persons who bought and consumed portions of the same meat were in nowise affected.

What Constitutes a Guarantee?

An interesting case under the Food and Drugs Act, raising a question as to the legal effect of guarantees, has just been decided in the Sheriff Court of Aberdeen; and as it is understood to be the first case of the kind in Scotland, considerable importance attaches to the decision. The article in question was a bottle of vinegar, to which was attached a printed label bearing the words, "Finest Malt Vinegar —Guaranteed Genuine." Notwithstanding this guarantee the vinegar was proved on analysis to be deficient in acetic acid to the extent of not less than 50 per cent. compared with vinegar of good quality, and not less than 25 per cent. compared with the lowest class of vinegar. In defence it was pleaded that the accused purchased the article as of the same nature, substance, and quality as that demanded by the prosecutor, and he had no reason to believe that it was otherwise when he sold it. He sold it in the same state in which he purchased it, in the belief that it was pure, and in accordance with the warranty given on the label affixed to the bottle. The question was, whether this was enough to protect the seller from the penalties provided in the Act, and especially whether the guarantee on the label was sufficient to secure him immunity. The Sheriff held that it was not; that the label was a mere manufacturer's label, which must be taken for what it was worth, and that such a warranty as was necessary to satisfy the requirements of the statute must be a written warranty.

THE CHEMICAL AND BIOLOGICAL ANALYSIS OF WATER.

By T. H. Pearmain and C. G. Moor, M.A. (Cantab).

Members of the Society of Public Analysts. Authors of "Applied Bacteriology;" "The Analysis of Food and Drugs," &c.

(*Continued from page* 532.)

THE COLLECTION OF SAMPLES OF WATER FOR ANALYSIS.

The greatest care should be taken in collecting samples of water for the purpose of analysis, in order to secure average and representative samples of the supply under examination. The amount of water required for an ordinary sanitary analysis of water is half a gallon, and the most convenient receptacle for containing the samples are the stoppered 80 oz., "Winchester Quart" bottles, which are readily to be obtained at any chemist's shop. Corked bottles should never under any circumstances be used. If a full analysis is required, as, for instance, in the case of judging the suitability of water for brewing or boiler purposes, a larger quantity of water is required, say, from one to two gallons. The bottles used for collecting the samples must first be thoroughly cleansed by washing with hot soda to remove traces of grease, and then with a little dilute hydrochloric or sulphuric acid, and then well rinsed with water until the last traces of acid are completely removed. It is preferable whenever possible to use new bottles, but whether the bottle is new or not it must be well rinsed with water several times, and lastly with distilled water and well drained. It is safest never to use bottles which have contained organic fluids.

If the sample of water to be examined is to be taken from a pump, it should be allowed to run to waste for a short time before collecting. In the case of tap water, it should also be allowed to run for a time before taking a sample, unless it is desired to examine the water for the presence of lead, in which case it may be advisable to take the first runnings, so as to see whether it is able to dissolve the metal through standing in the pipes. In taking samples from a river, streams, or lakes, care should be taken to avoid any floating scum, or the stirring up of mud from the bottom, and the sample should be always taken away from the banks. In taking samples from public supplies they should be collected from a hydrant in direct connection with the main, and not from cisterns or other storage receptacles.

No sealing-wax, linseed paste, or other form of sealing material should be put on the stoppers of water samples, owing to the danger of contaminating the samples, but the stopper should always be covered with a clean piece of parchment paper, the string used in fastening this can be sealed with sealing wax if desired. The bottles after labelling can then be packed in straw or other suitable packing material, and contained in hampers or boxes for carriage. Water samples should be sent off to the analyst with the least possible delay, so that the analysis can be put in hand as soon as possible. This is very important, as waters, particularly polluted ones, are liable to undergo chemical changes on keeping. It is also of the greatest importance that a proper record should be sent of the date of collection, preferably upon a label upon the bottle itself, of the source of the water, whether derived from pump, river, &c., particulars in reference to sources of possible pollution, such as proximity to cesspools, stables, sewers, or manufacturing establishments. In the case of wells the depth should given, and also the character of the local geological conditions should be given whenever possible.

Since the object of a water analysis is most frequently to determine as to whether it is fit for domestic purposes, too much importance cannot be insisted upon as to the necessity of supplying the analyst with these particulars as to its history. It is often difficult to give a correct opinion as to the purity or safety of a water without the knowledge of these facts.

When a bacteriological examination is needed upon a sample of water, special conditions and precautions have to be adopted for its collection; these will, however, be dealt with under the section dealing with the biological examination of water. For the ordinary chemical examination of a sample of water for sanitary purposes, it is necessary to have the following data, for expressing an opinion as to its freedom or otherwise from pollution with sewage, or other dangerous putrescible matter, and general suitability for domestic purposes:—

Physical characters and nature of sediment, if any.
Free or saline ammonia.
Albuminoid ammonia.
Amount of oxygen consumed for oxidation of contained organic matter.
Nitrogen present as nitrates and nitrites.

Total solid matter. Loss of same on ignition.
Chlorine.
Hardness.
Phosphates and poisonous metals.

STATEMENT OF THE RESULTS OF ANALYSIS.

Much confusion is caused owing to the fact that there is no uniformity in the numerical statement of analytical results. Owing to the fact that the difference between a pure water and a badly-polluted one, may only be the difference of a few parts or fractions of parts of the various constituents, say, in 100,000 parts of the sample, it becomes exceedingly difficult for the analyst to attempt to make the lay mind to realise the true significance of analytical data in water analysis.

The results of analysis are still commonly expressed in grains per gallon, *i.e.*, in parts per 70,000, since there are this number of grains in the gallon. Some analysts prefer to report the solid constituents as grains per gallon, and those representing the organic impurity in terms of parts per million (= milligrammes per litre).

The method of reporting in parts per 100,000 (= milligrammes per 100 c.c.) is undoubtedly the best, as, being founded upon a decimal system, they are at once comparable with analyses made abroad. This method of stating analytical data in connection with water analysis is in common use on the Continent, and is rapidly coming into use in this country. Results expressed as grains per gallon can be converted into parts per 100,000 by dividing by 7 and multiplying by 10, whilst multiplying by 7 and dividing by 10 converts parts per 100,000 into grains per gallon (= parts per 70,000).

When the results are desired in terms of grains per gallon, it is convenient to measure 70 c.c. for each estimation or a multiple of this quantity by means of a special pipette. This quantity (70 c.c.) represents a "miniature gallon," and the results obtained can at once be expressed in terms of grains per Imperial gallon. Since 1 c.c. weighs 1 gramme at the ordinary temperature, therefore 70 c.c., the miniature gallon, weighs 70 grammes or 70,000 milligrammes. Therefore milligrammes per 70,000 is equivalent to parts per 70,000 or grains per gallon. In the same way if 100 c.c. is taken for each estimation, each milligramme of constituent found represents directly parts per 100,000, since 100 c.c. = 100,000 milligrammes.

THE PHYSICAL CHARACTERS.

The sample is shaken up and poured out into a colourless glass tube 2ft. long and 2in. in diameter, which has been ground flat at the closed end, and the clearness, presence of suspended matter, colour, &c., observed.

Clearness.—The degrees of turbidity may be expressed as "faintly opalescent," "very slightly turbid," "slightly turbid," "turbid," &c. The turbidity or haziness in water is caused by the minute particles of suspended matter, the nature of which is subsequently determined by a microscopical examination. The best quality waters are, of course, brilliant and clear, but these qualities cannot be considered as any evidence of purity, for the most grossly contaminated waters may be both bright and clear.

Colour.—This is best observed by looking down the tube upon a white porcelain slab. Good waters possess but little, if any, colour when thus examined, at the most only a faint greyish-blue or greenish tint. If any yellow or brownish tinge is seen it will probably be due to the presence of a large amount of sewage pollution, or vegetable contamination in the form of peat, which frequently occurs in upland surface waters. Finely-divided oxide of iron and clay may also give rise to brown tints in water.

A marked greenish tinge may be communicated to water by chlorophyll—containing algæ. Water from rivers that receive the waste waters discharged from various manufactories may be variously coloured, particularly those from dye-works.

If considered necessary, a permanent record of the colour of a water, although comparatively unimportant, and seldom required in practice, can be made by means of the apparatus devised by Messrs. Crookes, Odling, and Tidy. In this apparatus the water is compared against dilute standard solutions of copper sulphate, cobalt chloride and ferric chloride. These are contained in hollow prisms, which are made to slide across one another in front of a circular hole in a metal shield. Thus, any desired combination of blue and brown tints can be obtained, and the colour of the water under examination is stated in so many millimetres thick of blue, and so many of brown. The valuable instrument known as Lovibond's Tintometer would be a more ready means of permanently registering the colour of a water.

Smell.—The odour of a water can be best ascertained by placing about 200 c.c. of the sample in a chemically clean stoppered bottle of about 250 c.c. capacity, and immersing this in warm water, at about 65 deg. Cent., for a few minutes. The stopper is then removed and deep sniffs taken at its contents. Any sewage or urinous odour, or any contamination with coal gas, sulphuretted hydrogen, &c., is thus easily detected.

A more delicate method than this is that of M. Boudriment, who shakes 100 c.c. of the suspected water with an equal volume of ether, which is then separated off and allowed to evaporate at the temperature of the room; the residue left after the evaporation of the ether is then carefully smelt. The test may be rendered yet more delicate by distilling a litre and collecting the first 50 c.c. that come over, and treating them with ether as above described.

Many natural waters, *e.g.*, peaty waters, give off peculiar and characteristic odours, which are very difficult to describe. The test of smell is, however, very unreliable, and is one into which a great deal of personal equation enters. Absolutely pure water is quite free from odour, but waters from some geological formations occasionally have a faint odour of sulphuretted hydrogen, particularly those from some sandy and clay formations.

It must not be overlooked that certain "mineral" waters contain large amounts of sulphuretted hydrogen.

Certain infusoria and algæ may be the cause of bad odours in water supplies.

The *Uroglena Americana* is frequently the source of a "fishy" odour, and is a frequent source of trouble in certain water supplies in the United States. Others give rise to an odour recalling cucumbers. The *Volvox globator* also gives rise to a fishy odour and taste. *Busaria gastris* gives rise to a seaweed-like odour, and the diatoms

Asterionella and *Tabellaria* sometimes give rise to an "aromatic" odour in water supplies. Recently the Cheltenham public water supply suddenly acquired a fishy odour and flavour, which was found to be due to a copious growth of *Chara fœtida* upon the walls of the reservoirs.

Taste.—The pleasant taste of a good water is due to the dissolved gases, such as carbon dioxide and air, contained therein. The flat taste of rain and distilled water is due to the absence of these gases. The sense of taste is practically useless as an indication of the purity or otherwise of a sample of water. Common salt can be present in amounts as large as 60 grains to the gallon, without causing a brackish taste. Iron salts, however, in very small amounts (as little as 0·2 grains per gallon) will give rise to a very decided chalybeate taste.

As stated above, various infusoria and algæ may be the cause of various peculiar and unpleasant flavours in waters.

A certain amount of discretion should always be exercised by the analyst before tasting samples the history and origin of which is unknown, as, for obvious reasons, the safety of such a procedure may be very questionable.

Reaction.—The degree of alkalinity or acidity possessed by a sample of water is not infrequently a factor of great importance. Most natural waters will be found to be faintly alkaline owing to the presence of calcium bicarbonate, and less frequently to sodium carbonate. Many waters are quite neutral in reaction. Badly-polluted waters may be alkaline due to the presence of ammonium carbonate resulting from the decomposition of the urea contained in urine. Many upland surface waters are decidedly acid, due to humic, ulmic, geic, and other organic acids, derived from peat. The waste waters of factories may be excessively acid or alkaline, and these may thus contaminate a large body of water. When necessary, the reaction of a sample of water is determined in terms of centi-normal acid or alkali, as the case may be, using dilute solutions of methyl-orange, phenol-pthalein, or lacmoid, as indicator. If the acidity disappears on boiling, it is due to carbon dioxide. Lacmoid possesses the advantage over phenol-pthalein that it is unaffected by carbon dioxide.

Aëration.—A good water, to be palatable, must be well aërated. The highest-class waters are invariably well aërated. Waters from deep wells, from the chalk and limestone, are frequently highly charged with carbon dioxide. Evidence of this is frequently afforded by minute gas bubbles collecting upon the sides of the bottle containing the sample. The estimation of the dissolved gases in water, which is sometimes required, will be dealt with later.

(*To be continued.*)

TO OUR READERS.

The Editor solicits the co-operation of readers in making THE SANITARY RECORD *more attractive by means of pen-and-ink sketches, photographs, and diagrams. There are many phases of sanitary work which lend themselves admirably to illustration. By this means not only individual articles, but the journal as a whole will be brightened.*

LIME, MORTAR, AND CEMENT: THEIR COMPOSITION AND ANALYSES.

By W. J. DIBDIN, F.I.C., F.C.S., &c.

(*Continued from page* 531.)

CHAPTER IV.

EARLY ART OF MANUFACTURING CEMENT AND MORTAR.

When we consider the question of the early use of artificial mortar and cement, it soon becomes clear that either moistened clay or the natural bitumen was employed by the ancients to cement the stones of the masonry together, but it is an open question as to what artificial mortar was first employed. It is clear that the Egyptians used mortar in their construction of the Pyramids, and from an analysis of that used in the Pyramid of Cheops is given by Mr. Cresy ("Theory and Practice of Engineering," pages 717 and 718), it would appear that in this respect they probably had not much to learn from our present-day knowledge.

The Greeks, as might be expected, used mortars with a lime base at a very early date, to cover walls constructed of unburnt bricks. According to Plinius and Vitruvius, the Palace of Crœsus, the Mausoleum, and the Palace of Attalus were thus protected, or ornamented in this manner. According to Strabo, the walls of Tyre were built of stone set with gypsum. (Burnell, "Limes, Cements, and Mortars.")

In Italy, the first people to employ mortar in their buildings were the Etruscans. The Romans, as is well known, derived all their knowledge of the arts from either the Etruscans or the Greeks. They added little to the general stock of knowledge as to the use of limes, but Vitruvius is the first author upon the subject whose works have descended to us, and according to him the ancients were by no means ignorant of many of the laws governing this matter; and, according to Burnell, Vitruvius was, in his opinion, as safe a guide as most of the authors who have treated of the subject until M. Vicat, whose work in the early days of the present century is even now quoted as classic.

Plinius and St. Augustine, continues Burnell, treat occasionally about limes and cements, the former principally to complain of the malpractices of the builders; the latter, to seek metaphysical comparisons. On the revival of literature, after the Cimmerian darkness of the Middle Ages, the authors who treated upon the art of building did little more than follow in the traces of Vitruvius. There was a difference of opinion, it is true, as to the quantity of sand which it was most advisable to use, some new limes, some puzzolanos, terrass, and ashes were employed to give certain other limes the faculty of setting under water; but until about the middle of the last century no advance seems to have been made towards ascertaining the principles which regulate this branch of chemistry.

It is, indeed, worthy of remark, our author wisely continues, that the more useful arts appear to be carefully studied until the practical results they are capable of producing are ascertained; then the rules drawn from such results are received implicitly for long periods, and any attempt to ascertain the laws which regulate them

is regarded as useless. We (the human race) appear to attain empirical knowledge quickly; scientific knowledge arrives at a much later period. So it was with limes, so it is with the casting and puddling of iron—a subject equally, if not more, interesting.

The first serious attempt (according to Burnell, page 4, *et seq.*) made to ascertain the causes which gave some limes the power of setting under water, and which modified their rates of hardening, was made by John Smeaton in 1756, in connection with the construction of the Eddystone Lighthouse. The results of his experiments are detailed in his account of the building of that work; Book III., Chap. III. The results he arrived at were very remarkable, not only for their practical utility, but also as an illustration of the ease with which a very acute observer may stop short on this side of the attainment of a great truth. Smeaton found that the commonly-received opinion that the hardest stones gave the best limes was only true as far as regarded each quality considered by itself. That is to say, that of limes not fit to be used as "water cements" those made of the hardest stones were the best for certain uses in the air; but that, whether obtained from the hardest marble or the softest chalk, such limes were equally useless when employed under water. He found that all limes which could set under water were obtained from the calcination of such limestones as contained a large portion of clay in their composition. His experiments led him to use, for the important work of the lighthouse, a cement compounded of blue lias lime from Abershaw, and of puzzolano brought from Civita Vecchia, near Rome. Smeaton, after giving a table showing that all the water limes were obtained from limestones containing clay in chemical combination in proportions varying from $\frac{3}{14}$ to $\frac{1}{17}$, goes on to say:—"That it remains a curious question, which I must leave to the learned naturalist and chemist, why an intermediate mixture of clay in the composition of limestone of any kind, either hard or soft, should render it capable of setting in water in a manner no pure lime I have yet seen, from any kind of stone whatsoever, has been capable of doing. It is easy to add clay in any proportion to a pure lime, but it produces no such effect. It is easy to add brick-dust, either finely or coarsely powdered, to such a lime in any proportion also, but this seems unattended with any other effect than what arises from other bodies, becomes porous and spongy, and therefore absorbent of water, as already hinted, and excepting what may reasonably be attributed to the irony particles that red brick-dust may contain. In short, I have as yet found no treatment of pure calcareous lime that rendered it more fit to set in water than it is in nature, except what is to be derived from the admixture of brass, puzzolano, and some ferruginous substance of a similar nature." Had Smeaton submitted the mixture of clay and lime to heat, and then ground the resulting clinker, he would have had "Portland Cement."

It was not until 1813, when Colets Descotils, on analysing the compact marl of Senouches which yields on calcination a lime capable of setting rapidly under water, found it nearly one quarter silica, which led him to the conclusion that the cause of the phenomenon consisted in the presence of a large quantity of siliceous matter, disseminated in very fine particles in the tissues of the stone itself. This view was confirmed by Vicat, who, in the course of a series of experiments carried out in Paris in 1817, composed hydraulic limes entirely by burning different mixtures of common lime, slacked spontaneously with clay; and the view that the cause of the setting of lime is due to the action set up by, or favoured by the presence of the silica, is now generally accepted.

There is, however, another factor which comes into play, and that is the alumina, which is always present in clay. In fact, as already shown, this substance is an essential element in its constitution, and the precise part which it plays in the molecular rearrangement yet remains to be ascertained.

NOTES ON
PRACTICAL SANITARY SCIENCE.

By WILLIAM H. MAXWELL.

(*Concluded from page* 534.)

GENERAL OBSERVATIONS ON REFUSE DESTRUCTORS.

The Question of Alleged Nuisance from Destructors.—Owing to defects both in the design and management of many of the early destructors, complaints of nuisance have frequently arisen, and have thereby brought all refuse destructor installations, both ancient and modern, into popular disrepute. When it becomes known that it is intended to erect a destructor upon any given site in a town, the case of its efficiency or otherwise is invariably prejudged, and numerous objections on the ground of its being a source of nuisance are at once conjured up by popular prejudice. It cannot be denied, however, that some of the old furnaces have been decided offenders in the direction indicated; but such is not the case with the modern improved type of high-temperature furnace, and oftentimes, were it not for the great prominence in the landscape of a tall chimney shaft, the existence of a refuse destructor in a neighbourhood would not be generally known by the inhabitants. At the present time there is no reason whatever why a destructor, properly designed and managed, should be a source of the slightest nuisance.

The nearness of inhabited houses to a destructor is not a matter of any great significance in regard to the question of the satisfactory working of the furnaces, as where there is a shaft of average height experience shows that when complaints of nuisance have been made, they usually originate from inhabitants who live some considerable distance from the site of the works, and especially from those residing in portions of the district approximately on a level with the top of the chimney shaft.

In the course of the inquiries made by the Engineer and Medical Officer of the London County Council, in connection with their joint report on "Dust Destructors," these officers, in several instances, were informed that there was much local opposition to the establishment of a destructor

when the scheme was in contemplation, and in some cases complaints of dust and smoke seem to have come to hand before any refuse was burnt in the furnaces.

It is a much more difficult matter than might at first sight appear to localise and trace to its source a given nuisance, and it is quite possible that in some instances the destructor has been accused of producing a smell which was really attributable to some other cause. The manager of a gas factory who complained that the neighbouring destructor brought the gasworks into discredit is certainly to be complimented on his ingenuity.

Any nuisances which may arise from destructor dust or pieces of charred paper are of a much more unmistakeable character than that of smells, as will be shown later, and, where these occur, must constitute a serious charge against the destructors concerned.

The use of forced draught, either by dry air or steam jets, is an effective means of preventing nuisance, and substantially increases the temperature of the furnace. Dr. Cameron writes in regard to the results of experiments carried out at one of the Leeds destructors that "the observed temperatures with the jets were 346 deg. Fah. above those without; but taking into account the fact that upon seventeen occasions in the one case against three in the other the temperature was too high to be registered, the real difference would be nearer 500 deg. Fah."

Out of forty-three towns included in the inquiries of the Borough Engineer of Ipswich, for the purposes of his report[1] on "Town Refuse Destructors," it appears that nineteen have on certain occasions had complaints of nuisances arising from the burning of refuse, which seem to have arisen from the escape of fine dust, small particles of burnt paper, and occasional smells, with the wind in a certain direction. These have been remedied by a screen fixed in the flue to intercept paper and fine dust, and the unconsumed gases destroyed by the application either of the Jones' cremator, which is fixed between the furnaces and the chimney, and maintained at a high temperature, or by steam jets for effecting the same end.

The Vestry of Paddington, in 1895, undertook investigations upon the destructor question, and, as the result of their inquiries, which extended to some thirty installations in various parts of the country, they conclude generally that the creation of nuisance in the process of burning is avoidable, and must be attributed to improper working of the destructor rather than to defects in the system. The nuisances that have been alleged to occur are dust from the tipping sheds and smoke shaft, and fumes from the furnaces and shaft. The scattering of dust from tipping sheds, they consider, can be obviated by the construction of suitably designed buildings, and dust and fumes from the shaft are due to insufficient length of flues or to overworking of the apparatus. Some smell has also arisen from the practice of cooling with a jet of water the hot clinker drawn from the furnace; but this can be done in a manner that will not permit the fumes to escape anywhere but up the flues.

Some instructive information upon the question of "Destructor Smells and Dust" has been given by Mr. Stevenson Macadam, Ph.D., F.I.C., &c., in the "Journal" of the Society of Chemical Industry, March 31st, 1896.

In regard to the soundness of the general practice of dealing with town refuse by fire Authorities are unanimous. So long as ten years ago—a considerable period in connection with the evolution of the refuse destructor—Mr. T. Codrington, M. Inst. C.E. (Local Government Board), reported that "the burning of town refuse by furnaces *already in use* appears to be successfully carried out. There is no accumulation of an offensive material at the works, and very little smell. Everything combustible is burned within a few hours of collection without nuisance, and at a cost which compares favourably with the old system of carting the refuse to tips. A valuable means is at the same time provided for effectually disposing of infected bedding and clothing, condemned meat and provisions, and the carcases of diseased animals. Further improvements may be expected, but the results already attained show that the destruction of the refuse of towns by fire is not only practicable, but is the best, and often the only way of dealing with it in a manner to satisfy sanitary requirements."

Since the above was written much has been achieved in respect of the possible improvements there anticipated. The following points are among the essentials for a *good* destructor:—

(1) The cells and flues must be so arranged that the fumes are drawn over the fire so as to enter into combustion with the heat from the furnace whilst on their way to the main flue. The function of a specially constructed cremator is thus effected in the furnace or cell itself.

(2) The temperature of the cell must be sufficiently high to prevent the possibility of any undestroyed deleterious or offensive gases escaping from the chimney shaft. For this purpose a forced draught of either dry air or steam is necessary.

(3) The main flue should have a large sectional area so that the heat and fumes may travel slowly, and thus maintain greater heat in the chimney.

(4) Dust screens are ineffective for the purpose for which they are designed, and, in a properly designed destructor, are unnecessary.

(5) The cooling influence of a boiler should not be introduced to the heated gases until they have fully performed their functions in the cells, and are on their way to the chimney shaft.

(6) The surplus heat should be as great as possible for application to any of the numerous uses already indicated, consistent with the efficient performance by the destructor of its primary functions as a refuse burner.

Old iron, tins, &c., may be sorted and disposed of where possible in the old metal market. Or, if it can be done profitably, the tins may be heated in a special furnace (a type of which has already been referred to) in order to recover the best tin and solder for re-use.

Considering the nature of the work, a destructor should be worked in three eight-hours shifts. A bath-room in connection with the works will be found a great boon by the workmen.

No destructor undertaking can be expected to be thoroughly successful unless intelligently and carefully worked, so as to derive the full advantage of its points of good design and construction.

The efforts of the stokers should be towards obtaining a good, hard, vitreous clinker which shall

[1] March 16th, 1896.

command a sale, or be useful for road-making and other purposes.

In the course of the inquiries of the recent deputation of the Cardiff Corporation, having inspected the refuse disposal of some fifteen districts, the experience gained led to the following general conclusions:—

(1) That destructor furnaces should be of the "high-temperature" type with forced draught.

(2) That, ton for ton consumed, the cost of destruction in high-temperature furnaces, including labour and repairs, is not greater, and possibly less, than in slow-combustion furnaces.

(3) That with the high temperature furnace (1) no cremator is required; (2) these furnaces are more suitable for generating steam power of a high pressure.

(4) That of the furnaces with forced draught, that of Messrs. Beaman and Deas, as seen at Warrington and Dewsbury, is the most efficient.

(5) That one great drawback to the destructor system is the creation of such large percentages (from 30 to 40 per cent.) of ashes and clinker to be disposed of subsequent to the burning. In nearly every town visited the getting rid of this large residue was no trifling matter, and in some cases amounted to a real difficulty incurring considerable cost.

(6) That as a result of these difficulties, some districts have resorted to the manufacture of artificial paving slabs, but these being only of a *third-rate* quality they could not recommend this method of utilising the clinker in a stone-quarry district, such as Cardiff.

(7) That clinker should not be used in forming road bottomings, owing to the damage sustained by water and other pipes in contact with same from corrosion due to chemicals existing in the ashes, &c.

(8) That the process most suited to their own district would be a combination of the separating plant as used by the Chelsea Refuse Disposal Company, including various machinery for manufacturing paper, crushing bones, &c., with the destructor system, and recommend the erection of a refuse destructor of the Beaman and Deas type for consuming the dust, animal and vegetable matter, diseased meat, infected bedding and clothing, &c. This combination they expect to be able to work at a profit.

The deputation found that in nearly every place they visited the person in charge of the works considered his method of disposal of the refuse and his type of furnace the best and unsurpassable. The opinions expressed in regard to the different types of furnaces were so utterly at variance that the members of the deputation were left to form their own conclusions more from what they *saw* than from what they had *heard*. Where low-temperature destructors were in use the manager, they found, advocated that particular class of furnace, and deprecated the use of high-temperature furnaces, as being expensive in repairs and more costly in working, requiring more firing and clinkering, &c., while the advocates of high-temperature furnaces allege that the fierce heat and forced draught throw off particles of silica in a melting condition, which adhere to the brickwork and preserve it; and so great is the growth of this incrustation, it has to be periodically knocked off.

THE END.

WHAT AND HOW MUCH TO EAT.

DR. SENECA EGBERT, in lecturing on the subject of "Food and Food Stuffs, Dietetics and Stimulants," in his hygiene and sanitation course at the Academy of Natural Sciences, Philadelphia, began by asking what we eat food for; and answered that we eat to live, save those of us who are so far on the wrong track as to make the old saw work the other way. First we eat to grow; and after that period we eat to make up for the destruction which is continually going on within us. So we eat first for growth, second for tissue, and third for heat and energy. Even when we do nothing the work of the heart alone is equivalent to going up a mountain 2500ft. high! Think of that!

Our diet should not be one-sided. We need all the foods; but not all at once, of course, though variety should be the spice of food, as it is of life. The proteids were considered first, and the fact that animals who feed upon herbs are rich in them was dilated upon. Indeed, wheat is rich in gluten; peas and beans, too. In the second-class came the carbohydrates, starch, and sugar; in the third, fats and oils; and in the fourth, salts. The old idea that proteids went to build larger bodies is buried, for every tissue doing work is full of proteids. The starch and sugar make the heat and energy. A working man needs more than an idle man, and both need more in cold weather than in warm weather. We need more fats and oils in winter also. We consume the fat quickest, and fat, be it known, is seldom taken in such quantities as to increase body fat. Any increase in fat in the ordinary person is due to the starches. Practically we need all four of these foods, though one or two may be dispensed with for a time.

As to the physiology of digestion, the body can use nothing that cannot become soluble. Many foods that present this difficulty are turned to sugar by the saliva. Test it by holding a bit of biscuit in the mouth; it will grow sweeter. The action of the gastric juice checks the action of the saliva, and when the food gets into the first part of the intestine, there is yet to be digested all the fats and a good share of the proteids. People don't thrive on digested foods, the girl without a stomach to the contrary, notwithstanding.

Dietetics is the science of keeping well or getting well on a food basis; and dieting rather than the use of drugs cannot be too strongly advised. We most of us have our peculiarities, and though a food is said to be all that is desirable, if it disagrees with us we must have the good sense to let it alone. If we do not, and also take into consideration our labour and the climate, there is trouble ahead. The lower animals may endure a monotonous diet, but human beings require variety. The more palatable the food is the more easily it is digested.

THE MANCHESTER REPORT ON SYSTEMS OF SEWAGE PURIFICATION.

(Continued from page 539.)

SUTTON SEWAGE WORKS.

The deputation visited these works on December 23rd, 1897, but in consequence of the lateness of the trains, owing to the prevalence of a thick fog, their intended programme was much disturbed, and the visit had necessarily to be of a very hurried character.

One member of the Committee (Councillor Maben) therefore visited the works the next day with a view of obtaining further particulars, and his report is here appended :—To Alderman Sir Bosdin T. Leech.—Dear Sir,—Having, by reason of the late hour of my arrival in London from Hendon Sewage Works, been compelled to stay another night in London, I resolved to utilise my time the following day (December 24th) by seeking further information on the subject from Mr. W. J. Dibdin, who, while he was chemist to the London County Council, promised me that he would show me the bacteria tanks at Sutton any time when I visited London. I called at his office; his partner (Mr. Thudichum) at once offered to escort me to the works, and we went direct to Sutton. We called on Mr. Chambers Smith, C.E., the Surveyor, who gave us the necessary permission to visit, and on our arrival at the works I found that the three bacteria tanks were in work, and the manager in my presence recharged one of these with crude sewage.

The following particulars I obtained on inquiry :—The population of Sutton draining to these works is 13,000. The daily dry-weather flow is 350,000 gallons. This is an average of 27 gallons per head, and its quality will perhaps be better understood if it is stated that the separate system of sewers operates, though in times of storm much subsoil water percolates into the sewage sewers.

These works, like many others, have undergone some changes in the method of treatment. They were originally built for the process known as "The International," but, except for the presence of a quantity of disused polarite heaped on the ground, and perhaps the outlet valves and pipes leading from the tanks, and a few pipe ventilators projecting from the ground at the sides of the small filter beds, there is nothing now left to indicate that that process had ever been in operation there.

The land comprising these works is about 25 acres in extent, and appears to be of a heavy clayey nature, entirely unsuited for land filtration without the addition of large quantities of cinders. After experiments the Council decided to change the filters to coke breeze, and also to construct others. It is one of the latter which Mr. Dibdin has frequently referred to both as to cost and capacity, and Mr. Thudichum pointed it out to me, and stated that its cost was only 4d. per superficial foot, or £726 per acre ; and on the question of capacity he was equally emphatic as to its ability to treat successfully and continuously a quantity of effluent equal to one million gallons per acre per day.

Prior to October, 1896, the whole of the sewage was treated by precipitation in six tanks, lime and copperas being used, and the sludge afterwards pressed ; but at that time the Council resolved, at the suggestion of Mr. Dibdin, to try the treatment of the crude sewage by passing it direct on to a coarse filter, and in November, 1896, one of the precipitating tanks (of which there are six) was used for this purpose, and after laying one 6in. centre main drain, and a few 3in. field drains laid herringbone, this tank was filled with burnt clay ballast to a depth of 3ft. 6in.

The figures of capacity given to me were :—Area, 183 superficial yards ; cubic capacity, 218 cube yards ; water without ballast, 36,094 gallons ; water with ballast, 13,500 gallons.

This process of formation was completed on November 21st, 1896. It was then filled, and has continued working ever since. It takes about three-quarters of an hour to fill, and about one and a-half hours to empty, and the crude sewage is allowed to lie in darkness two hours, and then drawn slowly off. The filtrate from this first process was apparently clear, but Mr. Thudichum assured me that it was not yet fit to go into a stream of small volume, and consequently it is run upon another bacteria bed of finer construction, of coke breeze or clinker or burnt clay, and I drew a sample of this, which appeared brighter and clearer than any filtrate I have ever yet seen. The Urban District Council are so satisfied with this method that they have turned two more of the precipitating tanks into use as bacteria beds, and have got the same result, and in a short time they will have abolished all their precipitating plant, and be able to dispose of all machinery and mixing gear, and also the sludge presses.

There are now three bacteria tanks in use. No. 1 was started on November 21st, 1896, and has since treated 12 million gallons. No. 2 was started on June 3rd, 1897, and has since treated 5½ million gallons. No. 3 was started on July 23rd, 1897, and has since treated 5 million gallons—total, 22½ million gallons ; and as the average of this sewage contains 60 grains of suspended matter per gallon, there has been got rid of without any trouble no less than 800 tons of sludge, containing 90 per cent. moisture. Each of these bacteria beds is stated to be as effective now as ever, and free from nuisance, and with a depth of 5ft. The Surveyor informed me that their working capacity was one million gallons per acre per day.

Plans are now prepared for the complete conversion of these works to this bacterial method, and it is estimated that on a daily flow of 350,000 gallons the saving effected to the ratepayers in working expenses will be £560 per annum.

Three acres of the farm are successfully appropriated to the growth of peppermint, which after distillation was found to have yielded a profit of £20 per acre.

Another kind of filter has been erected here, and is on the same principle as that at Hendon, which is the invention of Colonel Ducat , it is 300 yards super in area, but as it is under trial I can only refer you to my notes on the visit to Hendon Works. I may say that every facility was afforded to me of a complete inspection of the works without reserve of any kind. W. MABEN.

Sutton Sewage Works.—No samples were taken on this visit, and we therefore have no chemical data on which to base conclusions.

Report as to Cost and General Working of Filters.—This place is a centre of attraction for all students of the biological method of treating sewage, and is visited constantly by deputations.

The District Council has made experiments with many kinds of filters, and is so satisfied with the biological method that it has decided to convert the whole of the works to this system. The Council is proposing to discard the system of precipitation with chemicals. The economy to be effected by this proposed change is estimated by their Surveyor at £560 per annum. The question of cost, capacity, efficiency, and endurance may be illustrated from the Sutton Works :—Cost of filters, 3ft. deep, filled with burnt ballast, is equal to £726 per acre, the lowness of this cost being due to the fact that the works are situate on a bed of London clay, which is burnt for ballast *in situ*. Capacity : One million gallons per acre per day. Efficiency : A filtrate sweet and non-putrescible. Endurance : After three years' work no repairs or renewals are needed.

HENDON SEWAGE OUTFALL WORKS.

Owing to the prevalence of a thick fog on December 23rd the deputation were unable to visit these works. One member, however (Councillor Maben), reached the works, and subsequently the City Surveyor inspected them. The accompanying plan was kindly supplied by Mr. S. Slater Grimley, A.M.I.C.E., the Engineer and Surveyor to the Hendon Urban District Council, who accompanied the City Surveyor to the works on January 11th, 1898, and fully described them to him. The following general description may be of interest :—

The sewage from a population of about 17,000 is at present dealt with, but the works were constructed for a larger population. The total capacity of the tanks is 677,380 gallons. The present dry-weather flow is 500,000 gallons per day. It is treated with ferrozone ; the Surveyor, however, states that the greater portion of the sewage will be treated by alumino-ferric or ferric sulphate during the ensuing year. The wet sludge removed from the tanks amounts to about 300 tons per week. The works were let for seven years to the International Sewage Purification Company, who worked them under contract until February, 1896, when the contract expired. The working of the system has since February, 1896, reverted to the District Council. The high and low-level filters, which have an area of four acres, are composed of burnt clay with a layer of soil over same, the surface being covered with Leighton Buzzard sand 3in. thick, and there is a polarite filter of 500 yards superficial area in addition. The District Council are about to enter into contracts for the construction of further filters to be worked on the intermittent system. The new filters will consequently be of water-tight construction, and the filtering medium will be burnt clay ballast and coarse pan (coke) breeze with a layer of sand on the surface. They will have an area of 800 yards superficial. The wet sludge is run over a portion of the land adjoining the works, and is subsequently dug in. The total area of land belonging to the District Council is forty acres. Of this nineteen acres has been steam ploughed and subsoiled to a depth of 20in. to 22in. Concrete carriers are about to be provided for conveying the effluent to this land.

The sewage is of an unusually foul character, owing to the large amount of laundry work done in the district. It is, however, free from manufacturer's refuse or other trade refuse. The City Surveyor took samples of the crude sewage entering the works and of the effluent. These samples have been analysed, with the following results :—

Description of Samples.

Sewage, January 11th.—Turbid yellowish liquid, containing heavy, dark brown precipitate about one-twelfth of volume of liquid.

Effluent, January 11th.—Bright and clear, very slight amount of suspended matter.

Analytical Numbers.

	Grains per Gallon.				
	Oxygen absorbed, 4 hours.	Free and Saline Ammonia.	Albuminoid Ammonia.	Nitrogen as Nitrates and Nitrites.	Chlorine.
Sewage (shaken)	11·20	4·90	2·17	...	...
Sewage (settled)	5·26	5·07	·66	...	14·9
Effluent...	·70	2·40	·13	·44	6·3

Incubator Test.—Three Minutes' Oxygen Absorption.

	Grains per Gallon. Before Incubator.	After Incubator.
Sewage (settled)	2·36	4·90
Effluent	·24	·39 (?)

The sewage had become very putrid after incubation. There was no sign of putrescence in the effluent. Owing to the small quantity of sample left to determine the low oxygen absorption, the number ·39 is somewhat uncertain, and is probably too high. A determination of nitrogen as nitrites and nitrates in the effluent gave ·44 grain per gallon.

A small experimental filter has been constructed on the Ducat principle. This apparatus was, however, undergoing alterations at the time of the City Surveyor's visit, and had but recently re-started to work. Therefore, samples of the effluent from it were not taken.

Hendon Sewage Works.—No full description of the details of the precipitation process has been furnished. The results appear to be satisfactory, but the sewage is of much the same character as at Friern Barnet, with the addition of refuse from steam laundries.

(To be continued).

CARBOLIC ACID AND SUICIDE.—At the present time Middlesbrough seems to be suffering from a visitation in the shape of a mania for committing suicide by drinking carbolic acid. The cases of death by this means that have occurred recently number five or six, of which three have been within the past few days. On Friday last another case was added to the list, when a young married woman named Barbara Ann Stephenson (22) died from the effects of taking carbolic acid the previous night. At the inquest a verdict of "Death from taking carbolic acid whilst temporarily insane" was returned.

HOUSES LET IN LODGINGS.

Dr. Francis J. Allan, M.D., C.M., D.P.H., F.R.S. (Edin.), the Medical Officer of Health for the Strand District, and one of the hon. secretaries of the Incorporated Society of Medical Officers of Health, has presented an interesting and thoughtful annual report to the Strand District Board of Works. It contains some unique features, the special tables being particularly useful for comparative purposes, and they will repay the evident amount of pains and time which must have been bestowed upon them. He says:—"The year 1897 was an exceptionally healthy one for the country as a whole, the death-rate having been only 17·4 per 1000. Compared with the average in the ten years 1887—96, this is a decrease of 1·2 per 1000. London, notwithstanding the great influx of visitors during this memorable year, had a death-rate almost as low as the rest of England and Wales. The Strand district also compares favourably with other years, and it must be encouraging to your Board to see, as the results of your labours in one of the oldest of metropolitan districts, a steady improvement in the health of its inhabitants. The reconstruction of the unhealthy area, for which parliamentary sanction has now been obtained, together with the street improvements which your Board has or is in course of effecting, will render material assistance in maintaining that higher standard."

The birth-rate for the Strand was 23·69 per 1000, and the death-rate 20·01 per 1000. Dr. Allan's remarks upon houses let in lodgings are well worth perusal. He says:—

In a report presented to the County Council by the Medical Officer for the county, dealing with an inspection of the houses let in lodgings in the several sanitary districts of London, he says, in reference to overcrowding, to prevent which is one of the objects of the bye-laws regulating these houses, that if it be permitted in a single tenement, the conditions which are introduced into the house with it soon render the house unacceptable to others than persons of the same class as in the overcrowded tenement; and thus houses come to be devoted—intentionally devoted—to the accommodation of a class of tenants who appear to be indifferent to conditions of dirt and overcrowding. The absence of control by the landlord renders control by the Sanitary Authority more necessary.

During 1897, the number of registered houses were increased by four, while four of those registered in the past are now shut up. Much good has been effected in raising the standard of cleanliness in many houses which, while not being insanitary in construction, were not originally built to accommodate more than one family; and even now, with fair use, need not become insanitary. The object of these bye-laws is to do two things, to prevent overcrowding and to make the persons living in the houses acquire cleanly habits. In order to efficiently check the former evil it is necessary that the registered houses be visited early in the morning or late at night. Mr. Murphy, in the report quoted from, says, "It is obviously desirable to keep within limits domiciliary visits to dwelling rooms at night time, but it is evident that visits at unusual hours are in some cases necessary."

The teaching of cleanly habits to adults who have never been accustomed to them may be thought to be a task unlikely to be successful, but the experience already gained in this district is sufficiently encouraging to lead the Board to extend the operations of these bye-laws to a larger number of houses in the future. It has, of course, to be recognised that the beneficial effects of such bye-laws cannot be obtained in houses which are in themselves or their surroundings sanitarily bad, and it must likewise be admitted that the habits of many of the people who have lived under such conditions will speedily reduce the most sanitarily constructed house to a state as objectionable as their previous abode, unless some power exists to gradually lead them into better ways. To an extent the bye-laws give the opportunity for this to be done; the weekly visit of the Inspector, together with the advice he is able to offer, has an excellent effect, especially when it is known that failure to adopt it may lead to an appearance at the Police-court. Fortunately, this last resource was necessary in only one instance in 1897, when Assistant-Inspector Chamberlain was assaulted on visiting a registered house, resulting in his having his cheek cut and a tooth knocked out. His assailant was fined £3 and costs at Bow-street Police-court.

Sanitary Authorities have not given much thought in the past to the instruction of the people in the elements of healthy living, they have been occupied more with larger schemes of undoubted importance; but it must be recognised that there exists a great mass of ignorance, which is responsible for much suffering and many deaths. I have pointed out in previous reports that the excessive mortality from measles, diarrhœa, consumption, and other diseases might be much diminished. The large number of children who die or who grow up weakly is largely due to ignorance on the part of those in charge. Circulars dealing with the dangers of measles and whooping-cough have been distributed in this district during the last three years, and a Sub-Committee of the Health Committee has been appointed to prepare circulars dealing with other matters. Instructions are also circulated by the Jewish Board of Guardians among the Hebrews, who, since the tailors' strike in 1891, have in increasing numbers taken up their abode in Soho. But, in my opinion, the "circular" should only be used as an adjunct to personal instruction, and not as a substitute. I believe much good might be effected by Sanitary Authorities if they were to secure the services of women with nursing experience, grounded in the elements of hygiene, who could go from house to house and talk with the women on such matters as the care of their children, the importance of cleanliness in and about their houses, &c.; who could visit workshops where women were employed, and who would thus be of valuable assistance in detecting conditions requiring the attention of the Health Department. Ladies have been trained for this kind of work, and are employed in several country districts under the title of "Health Missioners."

Paisley.—Measles continues to spread in the northern district. Over the whole town upwards of 400 cases have been notified. Fortunately the rate of mortality is low among the sufferers.

THE SLAUGHTER-HOUSE AS A FACTOR IN THE SPREAD OF DISEASE.

GENERALLY speaking the place for slaughtering animals for food may be divided into large abattoirs and local slaughter-houses. The former are usually located in cities. The latter are used chiefly by the meat dealers of the country towns, and the animals slaughtered at these places are generally, if not always, for local consumption. In this article it is intended to discuss only the local slaughter-houses in their relation to disease.

The first matter to notice in connection with this subject is that every slaughter-house is from the very nature of things a centre of disease, and naturally the poorer the condition of the premises the more dangerous they are. These facts will appear clear if one considers what takes place at one of these houses. Even if only a few animals are slaughtered each week, the total number may amount to several hundreds during the year. Some of the animals are surely diseased.

It is well known that tuberculosis occurs in cattle. Now, if one or two hundred of these animals are killed at a country slaughter-house during the year, it may safely be assumed that one or more of them are tuberculous. Feeding the offal of these tuberculous animals to pigs will transmit the disease to those pigs, and these animals when used as food may in turn transmit tuberculosis to human beings.

The country slaughter-house is also the centre of infection for a number of animal parasites which are injurious to live stock, or, in some cases, even to man, and which are spread by means of dogs. Anyone who has visited one of these places will have noticed that dogs soon discover the premises as a good place to obtain food. While eating the discarded organs, they infect themselves with several kinds of parasites, of which the following are the more important.

The *Echinococcus hydatid* is found in the liver, lungs, and other organs of cattle, sheep, pigs, and certain other animals. It varies in size from a small object as large as a hazelnut or smaller to a bladder the size of a child's head. This bladder contains numerous tapeworm heads, and when eaten by a dog each head produces a small tapeworm. The eggs of this tapeworm are in turn transmitted to the various domesticated animals and man, and give rise to hydatids.

The disease it causes can occasionally be cured, but in man it is said to be fatal in five years in about 50 per cent. of the cases. It can, however, be almost completely eradicated if slaughter-houses are properly cared for.

The thin-necked bladder worm is found in the body cavity, in the omentum, &c., of cattle, sheep, and hogs, and is quite common in some localities. It developes into the marginate tapeworm when eaten by dogs. The eggs of the marginate tapeworm are then scattered by dogs on farms, in the road, &c., and infect cattle, sheep, and pigs with the bladder worm. It occasionally causes the death of young animals, as the bladder worm cannot be reached with medicines.

The gid bladder worm is found in the brain of sheep, and occasionally in other animals, but, fortunately, it is exceedingly rare, if present at all, in this country. When eaten by dogs, it developes into a tapeworm which produces numerous eggs. The dogs scatter these eggs on farms, sheep become infected with them, and contract the disease of "gid" or "turnsick."

The first and most important proposition to lessen the danger due to the slaughter-house is to reduce the number of places at which slaughtering is allowed, compelling all the butchers of a given town to slaughter at the same place.

This suggestion will naturally not meet with the approval of all the butchers. The objection will be made that they have money invested in slaughter-houses, and that any change will mean financial loss to them. To this the reply is that all or nearly all the country slaughter-houses are buildings which are not of much value; they are cheaply built, poorly arranged &c.; and the temporary loss to be sustained by the butcher will be infinitely less than the loss sustained in the course of time by the community. Further, these numerous local slaughter-houses are menaces to public health, and under these circumstances a small financial loss to a few individuals cannot be taken into consideration.

Objection may be raised that one butcher does not care to be subjected to having his business open to the gaze of other butchers. This objection answers itself. There undoubtedly are butchers who would object to having other butchers see the class of stock they kill or raise, and the sooner the Health Authorities exercise some control over these dealers the better.

As a rule, there is little complaint against slaughter-houses in case the odour arising from them is not especially offensive. When complaint is made the butcher sometimes cleans up the premises a little, and the matter is dropped. From the above facts, however, it must be evident that the odour arising from a slaughter-house is insignificant when compared with the sanitary side of the question.

TIN-LINED v. LEAD PIPES FOR WATER SUPPLIES.

AN interesting experiment relative to the influence of water on lead pipes is cited by Dr. Meredith Young, M.O.H., Crewe, in his annual report. It appears that the architect of the Crewe Isolation Hospital in his specifications omitted to specify pipes according to the water regulations in force in the borough, and ordinary lead water pipes were in consequence put in. When his attention was called to the matter, the architect gave an estimate of the cost of substituting tin-lined pipes for the water service already laid throughout the hospital premises, amounting to £73 os. 5d. The matter was subsequently considered at a meeting, but was deferred in order that experiments might be made to ascertain the action, if any, of the Crewe water on the lead pipes. The then Medical Officer of Health, Dr. H. Jones, made experiments with lead piping as used by the hospital contractor, and with tin-lined water-piping obtained from the corporation plumber, these pipes being both exposed to the action of Crewe tap water for five days. It was found that the water had not acted upon either of the pipes. Dr. Jones gave an opinion based upon these and other experiments, that no ill-effects would arise from lead pipes being used.

The Market, Lighting and Water Committee, at

a meeting held February 16th, resolved that Dr. Percy Frankland be asked to make experiments as to the action of the Crewe water upon unlined lead water pipes. Dr. Frankland's report came to hand in due course, and was duly considered by the Market, Lighting and Water Committee. The report stated that the water contained the following in parts per 100,000 :—Solid matter, 18·30; total hardness, 8·9; temporary hardness, 4·5; permanent hardness, 4·4. "It is free from ammonia and nitrites, it is alkaline to methyl orange and alkaline to phenol-phthalein on boiling. There is, therefore, nothing in the composition of this water which would lead to its being suspected of plumbo-solvent action." Two series of experiments were made by Dr. Frankland. In the first series, U-shaped leaden pipes, of ½in. internal diameter and open at each end, were filled, some with Crewe water and some with Birmingham water, which last is well known to be without action on lead.

The water, after standing for a number of hours, varying from twenty-four to sixty, was examined for lead, and this was repeated a number of times. Nine sets of experiments were made on these lines. These experiments showed that the mean quantity of lead contained in suspension or solution in water so treated was ·0675 part per 100,000, equivalent to 1-21st of a grain per gallon. The largest amount of lead was dissolved during the first two days of experiment, after which it fell, and on the ninth day two pipes exposed to the action of the water for sixty hours dissolved only ·05 and ·04 per 100,000 of lead respectively. In the second series of experiments, new leaden pipes, 3¼in. internal diameter and 2ft. in length, were closed at one end and filled with water, which was poured off and tested from day to day, Crewe water being compared as before with Birmingham water. The mean quantity of lead dissolved in ten experiments in which the water was in contact with lead for twenty-four hours was ·085 part per 100,000, or about 1-17th grain per gallon. The mean quantity of lead dissolved in four experiments where the water was in contact with the lead for sixty hours was ·080 part per 100,000, or 1-18th grain per gallon. Dr. Frankland concluded from both sets of experiments "that the plumbo-solvent power of the Crewe water is practically nil, for the water even after sixty hours contact with the leaden pipe contained only a very minute quantity of the metal. The amount of lead found in the water tends to diminish as the age of the pipe increases."

From the results of these experiments, and from the chemical composition of the water, Dr. Frankland concluded that the samples submitted to him were practically destitute of plumbo-solvent action, and that the tin lining of pipes for the supply of water was unnecessary.

Dr. Young himself made a few experiments with ordinary lead piping and with a specially prepared lead which is extremely easily attacked by a plumbo-solvent water, and from these experiments, as well as from a chemical analysis of the Crewe tap water, he was able to assure this Committee that tin lining of lead pipes in the borough was unnecessary.

YARMOUTH.—The Town Council has decided upon the erection of an isolated group of lavatories at a cost of £400 at the Town Hall.

THE TUBERCULE BACILLUS IN MILK

IN his annual report on the health of Liverpool during 1897, which has just reached us, Dr. E. W. Hope, the Medical Officer of Health for the city, gives some interesting details in reference to certain investigations which have been made during the year as to the presence of the tubercle bacillus in milk supplied to the city. Ordinary samples, in readiness for, or in course of delivery, were taken for the purpose, and forwarded to the investigators with due care. A total of 295 samples were examined, taken either from cans in dairies and shippons, from railway cans on arrival, on delivery at hospitals, or from unmixed milk. The milk dealt with fairly represented the city supply. The samples were forwarded in bottles specially prepared, numbers were put upon each, and the bacteriologists, Professors Boyce, Delepine, Hamilton, and Woodhead, were not informed of the places from whence the samples came.

Since the value of investigations of this kind depends upon the methods employed, and on the care with which they have been carried out, the examiners explain in detail the processes adopted by them :—

(1) The parasite causing the disease, the tubercle bacillus, may be looked for in the milk by means of the microscope.

(2) The effect which the milk has on animals may be tested by direct experiment, either by feeding them with the milk in question, or by the injection of small quantities of the milk under the skin, or into the peritoneum (the membrane lining the abdomen). When tubercle bacilli are present in the milk *in sufficient numbers to be a source of danger*, tuberculosis will be produced in the inoculated animal.

Professor Delepine, in his report, explains the reasons why injection under the skin is preferable to injection into the peritoneum. The lesions which are the result of such inoculation can be clearly recognised from those which might have been produced accidentally in some other way. When proper precautions are taken the injection of material free from tubercle bacillus will not produce lesions which can be mistaken for tuberculosis.

Professor Delepine employed two guinea pigs for each sample, and although he has every confidence in the subcutaneous method of inoculation as a test, this has not prevented him from using other methods which might furnish additional information. His report includes tables showing the re-action, specific gravity, the amount of cream separable in a limited time by means of the centrifugal machine, the amount of sediment, the number of cells, and the total amount of bacteria present. The tables also show the time which elapsed, within a few hours, between the time of milking and the time of examination.

Adverting to the value of the microscopic examination, Professor Delepine observes that even if tubercle bacilli were equally distributed through tuberculous milk—which they are not—a very large number of them would have to be present before one could expect to find one bacillus now and again in the few drops of milk used for a microscopical examination, *e.g.*, to examine one ounce of milk, at least 500 microscopical examinations would be necessary, each one taking twenty

minutes to half an hour, and if there were, say, 100 bacilli in that ounce, five such examinations would be necessary before it could be expected that one bacillus could be discovered, yet one bacillus in each drop would represent 10,000 bacilli in a pint of milk.

The simplest method in microscopic examination is to cause the impurities to be separated as a sediment, by means of the centrifugal machine, and then to examine a part of that sediment. From this it will be evident "That whenever tubercle bacilli are discovered by the microscopic method, they must be in such abundance as to make the milk infectious in a very high degree. I may say at once, he adds, that out of some forty specimens of unmixed milk obtained at various times from tuberculous cows, I have found the bacilli abundant in microscopic preparations only in two cases, and in these cases the udder was much diseased."

These observations render apparent the superiority of the inoculation method, concerning which the professor observes that in order to avoid injecting too large a quantity, and also to ensure that the number of bacilli injected should not be so small that the animal might resist the tuberculous invasion, he has injected half of the sediment separated from about three ounces of milk, mixed with two c.cs. of the milk from which it had been separated, under the skin of one guinea-pig, and the other half of the sediment, mixed with five c.cs. of the same milk, into the peritoneal cavity of another guinea pig. The animals were then kept in separate, disinfected cages, in a warm, well-lighted, and well-ventilated animal-house. The results of the inoculations varied. In some cases the animal showed no ill effect; in a few the milk proved highly virulent (from causes other than that of tuberculosis), and killed the animal within forty-eight hours. Others died from accidental causes, unconnected with the inoculations, and the remainder were killed at varying periods up to seven weeks, and a careful *post-mortem* examination was made, the organs being examined microscopically.

With regard to the guinea pigs referred to as showing local reaction at the seat of inoculation, this indicates the presence of a very large number of micro-organisms, and that the milk was not fresh, and it will be readily understood that milk containing irritant organisms of this character would be likely to give rise to the fatal inflammation of the bowels in infants, which is so exceedingly common during the autumn months.

The investigations carried on by Professor Boyce and the other examiners were conducted with the same careful regard to every detail, and the method employed was much the same as that employed by Professor Delepine. In the early experiments the milk was centrifugalised, and the deposit utilised. In subsequent experiments the sample milk was used. With regard to the microscopic examination, although this was employed, for reasons already stated, entire reliance could not be placed upon it. Due care was taken to ascertain that the animal was perfectly healthy before inoculation, and that it was kept under healthy surroundings in an effectively-ventilated animal-house, the animal being isolated as soon as any abnormal symptom developed. Full antiseptic details were employed where requisite.

Professor Boyce calls attention to a possible source of contamination to which reference has already been made, viz., the contamination of the milk from without by the tubercle virus, owing to excretions from tuberculous cows becoming dried with the shippon, floating about as dust and settling on the milk. He calls attention to the extreme susceptibility of guinea pigs to tuberculosis, and to the difficulty of saying when an animal is suffering from incipient tuberculosis. In order to prevent as far as possible any fallacy on this point, all the animals used by him were kept under observation for a considerable time previous to their inoculation. He says, "The chief point to pay attention to is that of never accepting any positive result, unless, firstly, the bacillus be found at the point or points of inoculation; secondly, unless the lymph glands running up from the point of inoculation are enlarged and tubercular: and thirdly, unless the tubercle has shown itself within a reasonable lapse of time."

The results of the bacteriological examination, says Dr. Hope, are conclusive that the supervision exercised in the city has proved more effectual than that which obtains in the country, and it is also made clear by the results of this examination, that consumers are safer, so far as tuberculosis is concerned, with milk from city shippons than with milk sent in from the country. Nevertheless tubercle must be eliminated absolutely from the milk supply of the city, and the most likely means to effect this end are a rigorous application of the existing orders and bye-laws.

HEALTHY DWELLINGS AND SANITARY TOWNS.

AT the request of the Organising Committee of the International Congress of Hygiene and Demography, held at Budapest in 1894, Professor Corfield prepared a series of resolutions relating to the sanitary conditions of towns and dwellings. These resolutions were submitted to a special joint meeting of three of the sections of the Congress, and were the subject of a very animated debate. They were ultimately referred to an International Committee, consisting of the following members:—Professor Corfield, London (proposer), Dr. Pistor, Berlin (seconder); Herr Andreas Meijer, chief engineer of Hamburg; M. G. Bechman, ingénieur en chef des ponts et chaussées, Paris; Professor Fodor, Budapest; Mr. Arthur Cates, architect, London; Herr Berger, chief architect, Vienna; Herr Lindly, engineer, Frankfurt-on-Main; and Dr. A. J. Martin, member of the Consultative Committee of Public Hygiene of France.

The resolutions were revised by this Committee and were submitted to the International Congress recently held in Madrid, where they were adopted as resolutions of the Congress. They may be taken to represent the maximum amount of agreement possible at the present moment among sanitarians of different European countries. They are as follows:—

(1) That the general health of the population is improved and the spread of diseases prevented in towns and dwellings by the immediate removal of all foul matters, and by a copious supply of pure water.

(2) That the paving of streets should be smooth, and, as far as practicable, impervious, to facilitate

cleansing, and also to prevent contamination of the subsoil.

(3) Special measures should be taken in the construction of houses to prevent the access of ground-air and moisture to the floors and walls.

(4) House drains should be arranged so as to avoid stagnation of their contents, and to secure a rapid flow to the street sewer. They should be impervious to liquids and gases, freely and continuously ventilated, and provided with syphon-traps to prevent the access of foul air to the houses.

(5) The public sewers should be so constructed as to secure the rapid and uninterrupted flow of the sewage to their outlets. They should always be freely ventilated.

(6) The streets should be as wide as possible in proportion to the height of the houses; this proportion should be fixed in each locality, regard being had to local circumstances and to climate.

Every inhabited building should be well lighted throughout its whole depth and arranged so as to have an access of air from at least two sides.

(7) Special regulations should be made in each locality by the Public Authorities with the view of enforcing the practical application of the principles herein laid down.

Governments and municipalities should resolutely and energetically carry out the preceding recommendations, especially those concerning the healthiness of dwellings.

MOSS SIDE.—At a recent meeting of the District Council, Dr. Owens reported that during the four weeks ended May 14th there had been 46 births and 16 deaths. The death-rate was 7·7 per 1000. This was the lowest recorded in the district since he came into office, whilst the birth-rate was unusually high.

CHURCH SANITARY ASSOCIATION.—Dr. Norman Kerr presided last week at a meeting of the Association at the Church House, Westminster, when the following resolution was carried :—"That the thanks of the Church Sanitary Association be accorded to the Government and the Home Secretary for the proposed revolution in the procedure with respect to criminal inebriates, and that, in the opinion of this Association, this valuable Bill would be greatly improved if some enactment were inserted applying compulsory procedure in the case of non-criminal habitual inebriates."

THE REGISTRATION OF PLUMBERS.—On Friday afternoon last General Laurie, M.P., introduced to Mr. T. W. Russell, at the Local Government Board, a deputation of educationalists, who wished to place before him a number of modifications they desired to see introduced into the Plumbers' Registration Bill. It was pointed out that under the present form of the Bill there was a danger of an undue proportion of the representation on the Registration Council falling to the Plumbers' Company, while the deputation considered that as the technically educative authorities bore so large a part in educating the plumbers, they ought to have large representation. Mr. Russell, in reply, said there was no great urgency in the matter, for the Bill was very unlikely to become an Act of Parliament this session. He suggested that there should be a conference of those interested in the common object aimed at by the principle of the Bill.

Sanitary Inspectors' Associations.

NORTHAMPTONSHIRE AND DISTRICT.

A LARGELY-attended meeting of the members of the Northamptonshire and District Branch of the Sanitary Inspectors Association was held on Saturday afternoon, at the Northampton Town Hall. The Mayor of Northampton, Mr. W. P. Hannen, presided, and was supported by Mr. G. W. Branson (Chairman of the branch), Mr. T. G. Dee (Westminster), Mr. T. E. Tidman, C.E. (Hon. Sec. of the Association), the Rev. Dr. Cox, J.P. (Chairman of the Brixworth Rural District Council), Mr. W. Turnbull (Bedford), Mr. J. Wills (Kingsthorpe), Mr. W. Abbott (Hardingstone), Mr. F. Bayes (Wellingborough), Mr. R. Dykes (Northampton), Mr. B. Pyles (Quildon), Mr. J. W. Treadwell (Daventry), Mr. J. Prentice (Wellingborough), Mr. L. Foster (Ampthill), Mr. W. R. Wood (Northampton), Mr. H. Garratt (Duston), Mr. W. Smart (Dalton), &c. &c.

DR. PAGET, the Medical Officer of Health for Northamptonshire, wrote regretting inability to attend.

The MAYOR, in opening the meeting, spoke of the important part which sanitation played in the health of a district, and of the usefulness of an association of Sanitary Inspectors.

Mr. BRANSON, in the name of the branch, welcomed Mr. Tidman and Mr. Dee.

Mr. DEE read a paper on "The Necessity of Unity Among Sanitary Inspectors." Unity among Sanitary Inspectors, he contended, was absolutely indispensable, for real unity would be beneficial not only to themselves, but also to the public, whose servants they were. United they could have more chances of successful endeavour to obtain laws, a more equal enforcement of the law as it stands at present, a free hand and a full responsibility to deal with conditions inimical to public health which they found in the course of their work, a fair salary and a safe tenure of office, and a certainty that for the future, should it come to them, when, after having given their best years to the public service, their resting time arrived.

Mr. TIDMAN followed with a paper on "The Sanitation of Country Houses, Villages, and Small Areas," in which he dwelt at some length on the principles which should be adopted, urging that, so far as possible, drainage should be kept outside the house, and there should be access chambers to all parts.

[We shall publish this paper in future issues.]

On the motion of Mr. SMITH (Irchester), seconded by Mr. TREADWELL (Daventry), a resolution was unanimously passed recommending Local Authorities to pay the expenses of the chairman or members of their respective Sanitary Authorities, and also of their Sanitary Inspector, in order to allow them to inspect various systems of drainage.

During the day six ordinary members and seven honorary members of the branch were elected, and the meeting terminated with thanks to the Mayor for presiding. Prior to the meeting the members of the branch dined together at the Black Boy Hotel, the Mayor of the town being in the chair.

General News.

ST. IVES.—The erection of an isolation hospital is under consideration.

BANGOR.—About £2000 will be borrowed from the Board of Works for the water mains.

LEAMINGTON.—Additional conveniences are to be erected at the Pump-room at a cost of £100.

HEDON.—The Town Council is desirous of joining Preston in procuring a pure water supply.

BAYFORD.—The Local Government Board has sanctioned the borrowing of £1600 for works of water supply.

MEOLE BRACE.—A Local Government Board inquiry has been held into an application for power to borrow £400 for water supply.

KEYNSHAM.—The Medical Officer of Health reports an outbreak of measles at Saltford, where eight families are affected by the epidemic, which includes twelve cases. His recommendation is that the local schools should be closed for three weeks.

STIRLING.—The County Council has referred to the Sanitary Committee to consider and report as to the advisability of fitting up a laboratory at the County Hall, and the appointment of a chemist to make analyses of water, sewage effluents, or other chemical investigations.

CROYDON.—At a meeting of the Rural District Council it was decided to take the necessary steps for obtaining a certificate at the earliest possible date from the Surrey County Council, authorising the adoption of the Housing of the Working Classes Act, 1890, Part III., with respect to the parish of Mitcham.

GLOSSOP.—At the last meeting of the Rural District Council a petition was received from the Leicester Board of Guardians calling attention to the proposal before Parliament to supersede the powers of the Boards of Guardians regarding vaccination. The members expressed their views against compulsory vaccination, and decided to give their support to the petition.

PERTH.—At a recent meeting of the Perth Water Commissioners the buildings for the new engines at the water-house were approved of. The addition consists of a new engine-house to be built to the south of the existing building. The elevation towards Marshall-place is carried out in the same manner as the elevation towards Tay-street. The plans have been prepared by Messrs. James Smart and Son, architects, Perth.

ROTHERHAM. — A Local Government Board inquiry has been held relative to the application of the Corporation for sanction to borrow £4000 for purposes of public baths. Ten years ago the baths were erected, and a loan was obtained amounting to £4100. Of this, there is still owing £3654. Practically ever since the opening ceremony took place serious leakages had occurred, owing to the foundations having given way, and in repairs and additions no less than £3345 had since been spent on the undertaking.

ROCHDALE.—The Corporation Water Bill, whose object is to enable the Corporation to buy up the Todmorden Waterworks, came before the House of Lords Committee last week. The Bill is opposed by the Todmorden Corporation on the ground that it is taking powers to provide works of its own. The borough of Dewsbury is interested in the scheme, and witnesses have been sent to London to give evidence before the Committee.

EDINBURGH.—In the course of last month the total seizures of unsound meat were 33, consisting of 8359 lb. of beef, 355 lb. of mutton, 68 lb. of pork, and 88 lb. of veal, making a total of 8870 lb. of meat condemned. Of that quantity 560 lb. of beef came from the country. There were eight cattle destroyed as suffering from tuberculosis, these having come from the country. No seizures of unsound meat were made in shops in the city.

LEDBURY.—The work of testing the yield of water at the bore-hole at Massington has been continued for a whole week without a break, and Mr. Berrington, the engineer, has now the satisfaction of reporting a good supply from that source. The depth of the bore-hole is 75 ft., and the actual number of hours the pumping was continued were 144, and during that time the yield of water was considerably over 133,000 gallons, the supply never once failing, the water keeping at a level of nearly 12½ft., which is equivalent to 1080 per hour.

WIMBLEDON.—AT the last meeting of the District Council a letter was received from the Local Government Board stating that the proposed arrangement of the isolation hospital appeared to be generally satisfactory. The Board asked the Council, however, to give an undertaking that instead of an unclimbable railing, as shown on the plans, a brick wall should be erected enclosing one portion of the grounds. It also asked for a detailed estimate of the cost of the proposed work and other information. The Surveyor mentioned that the cost would be nearer £15,000 than £10,000, which was the original estimate. The letter was referred to the Sanitary Committee. It would be interesting to know the reason for an advance of 50 per cent. on the original estimate. Perhaps it will be explained when the matter again comes before the Council.

ST. PANCRAS.—Mr. C. H. F. Barrett, Vestry Clerk of St. Pancras, in accordance with a resolution of the Vestry, recently sent a letter to Lady Henry Somerset, pointing out to her ladyship "that owing to the insanitary condition of a certain part of her property in Somers Town it has been condemned as unfit for human habitation, and that by order of the Local Government Board the Vestry of St. Pancras is compelled to undertake the clearance of the site, at a cost to the already overburdened ratepayers of £30,000, equivalent to a rate of 4½d. to 5d. in the pound. In this manner is the parish to be taxed for the faults of the freeholders, for it is solely due to their disregard of any other consideration than how to obtain from their wretched tenants the maximum of rents for the minimum of accommodation that the present disgraceful condition of things has come to pass. The Vestry ask her ladyship, in the name of justice, to contribute towards the compulsory improvement of her estate from the revenue she derives from St. Pancras."

SWANSEA.—A Local Government Board inquiry has been held respecting an application from the Corporation for permission to borrow another £100,000 on account of its new waterworks scheme at Cray. Mr. Jevons, deputy Town Clerk, explained that the Corporation was authorised by Act of Parliament to construct a water reservoir at Cray, to make a tunnel, and construct a line of pipes. At the present time it had simply carried out the laying of the pipes. The expenditure authorised by the Act was £270,000, which might be increased afterwards with the sanction of the Local Government Board. At the present time £97,406 had been spent on the laying of the pipes and the acquisition of the land, &c., which left £172,942 in hand. The lowest tender for the completion of the work of constructing the reservoir was £255,747, and consequently the Corporation would require another £100,000.

Personal.

MR. A. S. ST. JOHN has been appointed Medical Officer for the sixth district of Bromley union.

MR. C. C. GARFIT has been appointed Medical Officer for the Glenfield district of Blaby union.

MR. C. BLACK has been appointed assistant Medical Officer of the workhouse of Sheffield union.

MR. WILLIAM H. TURTON has been appointed Medical Officer of Health for the urban district of Heanor.

MR. R. H. BARRETT has been appointed Medical Officer for the Gedney Hill district of Holbeach union.

MR. J. PAXTON has been appointed Medical Officer for the Hamsterley district of Auckland union.

MR. A. E. CARRUTHERS has been appointed Medical Officer for the fourth district of Bath union.

MR. THOMAS MOONEY has been appointed Inspector of Nuisances for the urban district of Pudsey.

DR. W. P. TURNER has been appointed Medical Officer of the West Ham union workhouse and school.

MR. HENRY SIMPSON has been appointed Inspector of Nuisances for the urban district of Worksop.

MR. EDGAR M. JENKINS has been appointed Medical Officer of Health for the urban district of Calverley.

MR. R. I. C. RODGERS has been appointed Medical Officer for the Habergham Eaves district of Burnley union.

MR. J. T. BAXTER and Mr. H. H. May have been appointed Sanitary Inspectors for the Battersea sanitary district.

MR. D. M. F. GASKIN, M.I.C.E., civil and consulting engineer, has been appointed consulting engineer to the Newton-in-Makerfield Urban District Council.

MR. W. S. DIBBS has been appointed Medical Officer for the Hedgerley district of Eton union.

MR. JOHN HUNTER, son of the late Mr. John Hunter, merchant, has been appointed manager of the Electric Lighting and Fitting Corporation, Liverpool. Mr. Hunter has for some time been the electrician to the Allan Line Shipping Company, Liverpool.

Sewerage Schemes.

[TO MUNICIPAL ENGINEERS AND SURVEYORS.—The Editor will be pleased to receive items for publication relating to sewerage schemes projected or inaugurated, together with explanatory diagrams or photographs. The former should be drawn and lettered in black ink.]

EXPERIMENTS in filtering at the Long Eaton sewage farm have been adopted.

THE Town Council of Chard has accepted the tender of Messrs. Vile and Son, Glastonbury, at £112 12s. 6d. for drainage work at Shepton Beauchamp.

THE Local Government Board has issued a Provisional Order empowering the Gomersal Urban District Council to purchase compulsorily land situate in the township of Birstall for sewage works.

A LOCAL Government Board inquiry has been held at Aston with reference to an application by the Urban District Council for sanction to borrow several sums, including £2500 for works of sewerage, and £200 for the extension of the public baths.

THE recent suspension of the local bank at Weymouth was as disastrous to the Corporation of that borough as to the residents. The former had a sum of over £8000 deposited there for the purpose of meeting the calls of the sewerage contractor, and it appears that the whole of this amount is irretrievably lost to the ratepayers.

THE Local Government Board has given its sanction to the Barton Rural District Council borrowing £1130, and the Urmston Urban Council borrowing £2,374 for the extension and improvement of the joint sewage disposal works at Flixton sewage farm. Mr. C. C. Hooley, C.E., surveyor to the former Council, has successfully completed the construction at Davyhulme of a bacteria filter bed to prevent the pollution of Bent-lanes brook.

THE Hendon Rural District Council has received a communication from the Local Government Board in reference to the application to borrow £2550 for works of sewerage at Harrow Weald, which stated that although the proposed works were satisfactory, the outfall works were quite inadequate to deal with the volume of sewage, and that extensions were contemplated. Until these works were carried out the Board defers giving a decision on the application.

A LOCAL Government Board inquiry has been held at West Bridgford with regard to the application of the Urban District Council for sanction to borrow several sums, including £4000 for an extension of the sewerage on the Holme-road, and the Radcliffe-road, and for a low-level sewer on the Rectory-road.

AT the recent meeting of the Staffordshire County Council, Mr. W. G. Bagnall, chairman of the Sanitary Committee, reported that the Council, in conjunction with the Birmingham City Council, was progressing favourably with the question of the pollution of the rivers. In the county at the present time there were schemes of construction amounting to £325,000. The Chairman said it was very gratifying that the Corporation of Birmingham was co-operating so cordially with them. The report was adopted.

THE progress of the experiments with the bacteriological method of treating sewage at Knostrop was considered at a recent meeting of the Leeds Corporation Streets and Sewerage Committee. Alderman Harding, chairman of the committee, commissioned to watch the experiments on behalf of the Corporation, reported on the work so far accomplished, and suggested the advisability of providing additional filtration beds in order to expedite the test. Having regard to the varied nature of the experiments, it was felt that by merely using the tanks now in existence too much time would be occupied in arriving at safe conclusions as to the efficacy of the Dibdin process in its application to Leeds sewage. Mr. Dibdin also communicated to the committee his opinion that shallower beds should be used. Up to date the expenditure on the experiments, including professional fees, amounts to rather less than £4000, and the committee decided upon a further outlay not exceeding £5000 to provide additional filtration beds.

THE Drainage Committee, reporting to the Hampton District Council at its last meeting, stated that Mr. Anstie had submitted further figures with reference to the application for an additional loan. It was resolved that the item of £400 still due to Mr. Dickson for extras should be left out of the estimate, and to apply to the Local Government Board for a loan of £4000, such sum having been rendered necessary by the Council having been obliged to purchase a site for the sewage farm and by other unforeseen contingencies. It was also reported that £711 remained due to Mr. Dickson as half of the retention money on his contract, but owing to the serious delay in the carrying out of the work it was resolved that he be informed that the sum of £840, being the penalty provided by the contract in respect to forty-two weeks, will be deducted from the retention money. It was further decided to accept the offer of the water company to flush the five riverside tanks at £4 10s. each, and that tenders be invited for the construction of the bacteria beds at the outfall works. It is possible that more will be heard of the decision of the Council with regard to the penalty withheld. The contractor has his views upon the matter, and at present these do not agree with those held by the Council.

A LOCAL Government Board inquiry has been held at Buxton with reference to the application of the Urban District Council for sanction to borrow £1020 for works of sewerage, and £500 for the purpose of contribution towards the cost of rebuilding Otter Hole Bridge.

A LOCAL Government Board inquiry was held at Withington on Friday last with reference to an application of the Urban District Council for power to borrow £421 for sewerage works on the Fielden Park estate. The Surveyor explained that the proposed works consisted of replacing the old sewer in Mersey-road with a new 12in. sewer pipe. The present sewer was open jointed, and was unprovided with manholes and ventilators. There had been serious complaints from residents in the neighbourhood. The Inspector, in closing the inquiry, said he would represent the urgent character of the case to the Local Government Board.

A LONG discussion took place at a recent meeting of the Sileby Parish Council, on the management of the Sileby sewerage disposal field, a large portion of which has been cleared and ploughed, and a layer of coke put down as a filter, whilst plans and details are being discussed as to a more successful mode of disposing of the sewage than has hitherto been in operation. As the Council considered that a definite arrangement had not been made with the Rural District Council with regard to the management of the field, the clerk was instructed to write to that body asking it to receive a deputation, so that the Parish Council might know its exact position and powers in the matter.

THE Sanitary Committee of the Pater Ward of the Pembroke Town Council recently had before it what may be regarded as the ultimatum of the Local Government Board. At the last meeting the Committee resolved to ask the Board to receive a deputation for the purpose of hearing objections to the amended scheme, which has for its outlet the Carr Rocks Spit instead of the Front-street outlet, as favoured by the Council, and adopted in the plans of Mr. Beesley, C.E., prior to the objections of the Admiralty, and also to discuss the question of damage to the oyster fishery. The Committee had received a letter from the Board refusing to receive a deputation, and asking that the amended plans be sent forthwith. After much discussion, in which the overbearing attitude of the Board was deprecated, a resolution was passed in accordance with the Board's demands. This will involve an expenditure (with water and present indebtedness) of no less than £80,000, including £4400 for the suburb of Bufferland, whereas the entire borrowing powers of the whole borough extend to only £72,000. The people of the town are for the most part artisans employed in the dockyard, and their incomes are not great. Consequently, unless the loan cannot be negotiated, because of the questionable security, the already burdened ratepayers will have to undertake an immense responsibility for the next thirty years.

Lighting.

AT a recent Colwall parish meeting it was decided to allow £42 to be spent for lighting the parish for the ensuing year.

THE Aberdeen Town Council has accepted the tender of Messrs. Siemens Bros. and Co., at £12,138 for the extension of the electric main cable to the harbour and west end of the city.

A LOCAL Government Board inquiry has been held at Chesterfield into an application by the Chesterfield Gas and Water Board for permission to borrow £1744 for gas and £662 for water purposes.

THE Town Clerk of Leeds has received from the Local Government Board an intimation that the Provisional Order enabling the Corporation to issue stock, irredeemable or otherwise, for the purchase of the undertaking of the Yorkshire House-to-House Electricity Company had been made, and would shortly be submitted to Parliament for confirmation.

THE directors of the new Monifieth Gas Company have just completed the feuing of the two acres of ground on the south side of the railway to the west of Lyell's Jute Works for the erection of the proposed gas works. The price is said to be 1s. 6d. per pole, a very reasonable arrangement. A lye will be provided from the railway adjoining, and no cartage will be necessary, thus saving a considerable item of expense. The directors are all members of the Burgh Commission.

IN connection with the proposed electric lighting at Llandudno, at a recent meeting of the Urban District Council, Mr. Johnson read the report of a deputation from the Council to the promoters of the light railway, from which it appeared that the company practically conceded all the points insisted on by the Council. In connection with this matter the Electric Lighting Committee submitted a report by Mr. Preece, in which he recommended the adoption of the overhead system for the proposed light railway in the district under the control of the Council. The report was adopted.

AT a recent meeting of the Shoreditch Vestry the Electric Lighting Committee presented a statement of accounts showing the work for the nine months ended March last. The power for the dynamos is obtained from the dust destructor, the consumption of coal being less than a ton a day. Altogether 491,107 units had been generated, of which 80,791 had been used for lighting the streets, 203,504 by private consumers, 156,725 used on the works, and 50,087 unaccounted for. The accounts showed a profit and balance of £1701 17s. 9d. The Vestry resolved to borrow a further sum of £15,700 for the purposes of the Committee.

A BILL to confirm the Provisional Order made by the Board of Trade under the Electric Lighting Acts, 1882 and 1888, in regard to electric lighting at Ilfracombe, came on Wednesday, the 18th inst., before the House of Commons Committee on Unopposed Bills. The preamble was proved, and the Bill ordered to be reported for third reading.

THE Salford Town Council at a recent meeting agreed, on the recommendation of the Electric Light Committee, to adopt plans for a new generating station on land in Strawberry-road, Pendleton, at an estimated cost of £28,000. Councillor Haworth, chairman of the Committee, said that the Committee was considering plans for the application of electric traction to the tramways. It had already gone as far as it dared in supplying the current to consumers. The proposed new station would not entail any charge on the rates, for as soon as they began working, interest and sinking fund would be provided out of the revenue. The electricty works were making gratifying progress.

THE foundation stone has just been laid of the buildings now in course of erection as an electric lighting station at High Wycombe. A site for the electric light station was found in a meadow adjoining Lily's-walk. The necessary buildings have been designed by Messrs. Moxham and Son, of Wycombe, and include a boiler-house, engine-house, accumulator-house, and various offices. The contract for their erection has been entrusted to Mr. Henry Flint, whose tender amounted to £2383. The fitting of the works with an electric lighting plant has been placed in the hands of Edmundson's Electricity Corporation, Limited. The fitting of the plant is under the supervision of Mr. J. C. Wigham, representing Messrs. Edmundson, and of the resident engineer, Mr. Fippard.

Law Cases.

IMPORTANT ACTION RESULTING FROM PTOMAINE POISONING.

(*Before* Mr. JUSTICE HAWKINS *and a Special Jury.*)

GILES *v* CHARD AND SONS.

THIS was an action brought by Dr. William Broome Giles, the plaintiff, against the defendants, who carried on business as butchers at 101, Gloucester-road, for damages for breach of contract in supplying to the plaintiff meat that was unfit for human food, in consequence of which the plaintiff and his household became ill. The action was consolidated with ten other actions which were brought by the different members of the plaintiff's household who were taken ill.

Mr. A. T. LAWRENCE, Q.C., and Mr. A. G. JAMES appeared for the plaintiff; and Mr. JELF, Q.C., and Mr. A. CARRINGTON for the defendants.

Mr. A. T. LAWRENCE, Q.C., in opening the case for the plaintiff, said that in July, 1897, the plaintiff occupied a flat at 169, Queen's-gate. On Saturday, July 3rd, the defendants, with whom he dealt, supplied the household with some ribs of beef weighing about 8 lb. The beef was cooked that

evening, and was consumed by the household on Monday, July 5th, and on Tuesday, July 6th. All the household partook of it except one young lady, and by Thursday, July 8th, all the household, including a dog, became ill, and were found to be suffering from ptomaine poisoning. The young lady who did not partake of the beef, however, did not become ill. A complaint was at once made to the defendants' foreman, who was at first disposed to meet the plaintiff and to pay any expenses to which he had been put, but when the plaintiff made a claim upon the defendants themselves they repudiated liability.

Dr. William Broome Giles, the plaintiff, said that his household in July consisted of his wife, his daughter, his mother, Mrs. Caroline Giles, Miss Williams, the governess, Jane Richards, the cook, Louisa Hart, the housemaid, Florence Hart, her sister, Catherine Isaacs, the nurse, a manservant, and Mr. Bacon, a guest. The witness had supper at home on Sunday, July 4th, but did not partake of the beef. On Tuesday, July 6th, he went to Lord's to witness the Oxford and Cambridge match. They had sandwiches for lunch made of the beef. He and his wife partook of them. He noticed that they were tasteless. He became ill during the night. Some of the symptoms continued for a month. His wife also was very ill. His mother, his daughter, the nurse, the housemaid, and the footman all fell ill, and their symptoms were identical with his own.

Cross-examined by Mr. CARRINGTON, he said that the defendants' foreman saw him with regard to the matter, and promised to pay any reasonable expense he had been put to. The foreman wished to have the remains of the meat examined, but it had then been eaten up. The dog ate the remains. No analysis of the meat, therefore, was ever made. It was on Friday, July 9th, that he first came to the conclusion that the beef was the cause. On that day he sent word to the defendants' foreman. It was said that ptomaines sometimes came into existence after the meat was cooked. On a hot day in a close place they might be so developed. The meat was kept in a meat safe at the back of the flat. The meat safe was in a small place or well surrounded by the building, which was seven storeys high. The witness's flat was on the first floor.

Re-examined by Mr. A. T. LAWRENCE, Q.C. He saw the dog ill on Thursday. It was almost paralysed. He continued to deal with the defendants because their foreman offered on behalf of the defendants to make reasonable compensation, and he asked the witness not to mention the matter to any one else in the building. In October he asked the defendants to make compensation. They repudiated liability.

Dr. Pierce Gould, of 10, Queen Anne-street, who attended on the plaintiff and his family on Thursday, July 8th, said they were suffering from weakness and feverishness, pains in the limbs, violent vomiting, and diarrhœa. These symptoms were consistent with ptomaine or food poisoning. The period of incubation of this form of poisoning was from four to forty-eight hours.

Cross-examined by Mr. JELF, Q.C.—The place in which the meat was kept was favourable to the development of bacteria. Bacteria might be developed in almost any article of food.

Re-examined by Mr. A. T. LAWRENCE, Q.C., he said that ptomaines were more liable to occur in diseased meat. At the stage when they were most poisonous it would be impossible to detect them by smell.

In answer to his LORDSHIP, he said that it was exceedingly difficult to test, by means of an analysis of the vomit, the presence of ptomaines. The witness did not think it necessary to make such an analysis.

Jane Richards, the cook, said that the meat arrived at about 5 p.m. on Saturday, July 3rd. The witness noticed nothing particular about it. She cooked it at once. She roasted it in the oven.

Mr. JUSTICE HAWKINS: That would be baked.

Mr. A. T. LAWRENCE, Q.C.: It is the modern way of roasting.

Mr. JUSTICE HAWKINS: It is a bad habit.

The witness, continuing, said that after the meat was cooked she put it in the safe. The meat was served in the dining-room for luncheon on Monday, and on the same day the servants had it for supper. The witness and one of the other servants partook of it. It was served again in the dining-room for luncheon on Tuesday, and sandwiches were made of it. It was finished off by the servants at supper on Tuesday. There were then present herself, Louisa Hart, Florence Hart, Catherine Isaacs, and Palmer. The dog had some at luncheon time and after supper on Tuesday. The dog was ill on Thursday morning. The witness began to feel unwell early on Wednesday morning.

Cross-examined by Mr. JELF, Q.C., she said she stewed the bones with some vegetables on Monday for soup. The soup smelt bad and she threw it away. She thought the smell was due to the vegetables. There was other meat in the house on Monday and Tuesday. There were two ducks, which came in on Saturday. They were finished on Monday. There was also a large quantity of bacon. The nurse, Catherine Isaacs, and Miss Violet Giles did not like bacon, and never ate it. There was also some steak, which was finished up on Sunday. At first it was suggested that the bacon was the cause of the trouble. The cider, too, was thought of. None of the vegetables used were tinned. The vegetables she put into the soup, which were carrots and turnips and onions, were not sent up for the table. The witness never served carrots with duck, nor with roast beef. The dust was taken away every morning in a zinc tin. It was taken down the lift in the "well." There was plenty of air in the well. Louisa Hart was taken ill at about twelve o'clock on Tuesday night. The last case of illness took place on Thursday.

Dr. Peter Giles, the plaintiff's brother, said he was now in charge of a militia hospital. He saw his mother, Mrs. Caroline Giles, on July 23rd, and found her to be suffering from the effects of an irritant poison. Dr. Hawksford Hincks and the witness treated her for ptomaine poisoning with success. The general opinion was that all meat contained ptomaines. With the development of bacteria a chemical change took place in the ptomaines, and they became poisonous. This happened most frequently when the animal from which the meat came was diseased. It was not always apparent. Bacteria were the products of putrefaction. Until the bacteria acted on the ptomaines there would be no indication of ptomaines. When the meat began to putrefy there would be marked indications of the ptomaines such as

a cook would be able to detect, provided that there was no fraudulent coating to conceal it, but at the early stages the ptomaines were not perceptible. Cooking would preserve the meat. There would be no smell before putrefaction set in. The periods of incubation of ptomaines which had come under the witness's notice were from 11 to 53 hours. These figures were based on cases which occurred in an epidemic which took place in Herefordshire in 1896.

Cross-examined by Mr. JELF, Q.C., he said that meat perfectly good in the hands of the butcher might become poisonous after its delivery to the customer. The place where this meat was kept was favourable to the development of bacteria, unless there were a draught.

Mrs. Giles said that the "well" was about 20ft. to 30ft. square. A door led into it on the ground floor from the street outside. This caused a draught in the well sufficient to bang the kitchen door. She ate some of the beef sandwiches for luncheon at Lord's on Tuesday, July 6th. She was taken ill on Thursday morning at about 2 o'clock.

Mrs. Caroline Giles, the mother of the plaintiff, said she was staying with her son in July last. On Tuesday, July 6th, she had luncheon with the plaintiff's daughter, Violet, and the governess, Miss Williams. All of them partook of the beef. The witness began to feel ill on Thursday afternoon. She was confined to her bed until July 19th.

Cross-examined by Mr. CARRINGTON: She could not say what she ate for breakfast or dinner on Tuesday. She was positive it was the beef that caused her illness.

Mrs. Brinsmead, *née* Williams, late governess to the plaintiff's daughter, said she partook of the beef on Monday, July 5th, and again on Tuesday. She began to feel ill on Wednesday evening about eight o'clock. On Thursday she felt sick, but went to 169, Queen's-gate. During the afternoon she became worse, and continued to be ill for some days.

Cross-examined by Mr. CARRINGTON: She noticed that the beef was nasty, tasteless, and of a dark colour. She did not complain. Governesses did not usually complain.

Mr. Harley Bacon said he was a visitor at the plaintiff's in July last. He was at luncheon on Monday, July 5th. He ate beef. He was taken ill on Wednesday morning. His illness continued for three days. With the exception of that luncheon he had not had meat at the plaintiff's house.

Cross-examined by Mr. CARRINGTON: Three days after he was ill he talked with the plaintiff and his family, and they came to the conclusion that it was the beef. He neither ate bacon nor drank cider at luncheon on July 5th.

Miss Rawlins said she lunched with the plaintiff on Monday, July 5th. She did not partake of the beef. She had duck and salad, and was not taken ill.

Mr. JUSTICE HAWKINS: That only amounts to an acquittal of the duck.

Louisa Hart, Florence Hart, Katrene Isaacs, and John Palmer all stated that they had eaten the beef, and were taken ill within two days afterwards.

Dr. Sidney Martin, Professor of Pathology at the University College Hospital, said he had made a study of bacteriology. Ptomaine poisoning was really a synonym for poisoning by food. It was not true to say that bacteria were always present in meat. Ptomaine was a word invented to indicate a poisonous alcaloid found in corpses. It was produced by bacteria. He never used the word himself, because it was not a correct term. Bacteria were living things, and ptomaine was a chemical substance. It would be impossible to come to any conclusion as to the time when a piece of meat became poisonous without an examination of the meat. It would be impossible to tell whether meat was poisonous until putrefaction set in. Poisoning by food was produced by changes in the food produced by bacteria. It seemed probable that unsound meat—meat of a diseased animal—would go wrong by means of bacteria sooner than sound meat. Heat, moisture, and dust were most conducive to putrefaction. The whole subject of bacteria and ptomaines was very obscure. The air, especially in London, was full of bacteria.

Cross-examined by Mr. JELF, Q.C., he said that there were two classes of poisoning by food. The first was when the bacteria had already developed in the food, and the second was when the bacteria developed after the food was consumed. In the latter case the period of incubation would be longer. The witness was further cross-examined with the view of showing that the fact that the period of incubation was prolonged in the case of the plaintiff and his household showed that the meat had not become poisonous while in the possession of the defendants.

Mr. JELF, Q.C., then opened the case for the defendants. Their case was that the meat sold to the plaintiff was perfectly good when it left their possession, and it was suggested that if the beef was the cause of the illness of the plaintiff and his family, it became bad while it was in the plaintiff's possession.

Mr. Alfred Chard, one of the defendants, said that the ribs of beef sold to the plaintiff on July 3rd were part of a hind-quarter and fore-ribs bought by himself at the London Central Meat Market on June 30th. It was Scotch beef, and was perfectly sound. He had disposed of the remainder and had received no complaints about it.

Before the defendants' case was concluded the jury interposed to say they had made up their minds, and found a verdict for the defendants.

Judgment was accordingly given for the defendants in this action, and in the ten other consolidated actions.

LONDON.—At the meeting of the County Council on Tuesday last, it was decided to advance the salary of Mr. Haward, Comptroller, from £1000 to £1250, an increase of £50 to be given at once, the remainder in two annual increments of £100 each. The highest testimony was given as to the value of Mr. Haward's services to the Council.

BATHFORD.—Another report has been presented to the Bath Rural District Council by Mr. E. H. Sheppard, the surveyor, on the question of the scheme for supplying Bathford with drinking water. He estimated that the cost, allowing £109 for contingencies, would be £1500, this including the expenses of a reservoir to hold 100,000 gallons, a wind engine, street fountain, &c. This report, with plans, has been remitted to the Parish Council for consideration.

Notes and Queries.

[Subscribers have the privilege of obtaining advice in this column on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed to THE EDITOR, "Notes and Queries," THE SANITARY RECORD, 5, Fetter-lane, London, E.C.

NOTE.—If an answer be required immediately, a stamped addressed envelope must be enclosed, when we will endeavour to furnish a copy of the answer by post, as owing to the large number of queries received we cannot guarantee the insertion of a reply in the succeeding issue.

1088. — CALCULATION OF CUBIC SPACE: BOOKS ON.—"W. W." writes:—"Can you please recommend me any book dealing with the measurement of contents of pipes and cisterns as regards quantity of water?"

Answer.—Either of the two following books will be found suitable, viz.:—Maxwell's "Calculation of Cubic Space," price 2s.; or Clarke's "Calculation of Cubic Space," price 1s. 0½d., obtainable from our office.

1089.—FOOTPATH: DAMAGE CAUSED BY TENANT.—"Surveyor" writes:—"My Council have not long ago put in repair a public footpath which runs through ploughed land. Subsequent to the work being done the occupier has damaged it very seriously by carting across it. Will you please state whether we have any remedy against him?"

Answer.—If the footpath was dedicated to the public, subject to the right of the occupier to plough through it or cart over it, there is no remedy against the occupier. If, however, there is no such right, the occupier may be indicted or proceedings taken against him under Sec. 72 of the Highways Act, 1835, for causing damage to the footpath.

1090.—DISINFECTANTS FOR FUMIGATING AMBULANCE.—"A. K." writes:—"I shall esteem it a favour if you will give me the name of any disinfectant that is not of a corrosive nature that might be used for the purpose of fumigation of an ambulance after the conveyance of infectious cases."

Answer.—An excellent disinfectant is that produced by the generation of formalin gas as described in our reply to Query 1079 in our issue of May 20th. Where this cannot be carried out we recommend disinfection by sulphurous acid gas, the process of which is described in reply to our Query No. 1092 in this issue. Our correspondent should procure Rideal's "Disinfection and Disinfectants," price 12s. 6d., wherein he will find numerous other methods of disinfection described.

1091.—DRAIN OR SEWER: PREMISES WITHIN THE SAME CURTILAGE.—"Subscriber" writes:—"Herewith I hand you sketch" (not reproduced) "of a block of property, consisting of seven cottages with gardens in front, spare ground and conveniences at one end, flagged footpath at back, and public roadway at other end. The dotted line from the back and end of house indicates probable course of stone drain from back houses to sewer in adjoining roadway. At the head of drain A the sinks of two houses discharge into it at B. A third house is similarly connected with the drain at C, in a fall pipe from the roof gutter, and at D it is probable the drains from the first houses join. The whole of the property is surrounded by a stone fence, and belongs to one owner. Query: (1) Is any portion of the drain a sewer, and if so, which? and would the Local Authority be liable for the repair or re-construction of any portion? (2) How would the word curtilage apply in the case like the one shown?"

Answer.—We have previously referred to the unsatisfactory state of the law in regard to combined drainage. By Sec. 4 of the Public Health Act, 1875, "drain" means any drain of, and used for, one building only, or premises *within the same curtilage*, and "sewer" includes sewers and drains of every description except drains to which the drain interpreted as aforesaid applies. In the case put before us by our correspondent it is necessary to determine whether the premises drained by the combined drain are within the same curtilage. We are of opinion that the premises are within the same curtilage, and that the drain in question is not a sewer vested in and repairable by the Local Authority. Reference should be made to our answer to Query No. 1019, in our issue of April 1st, wherein we cite the three leading cases on the subject of combined drainage.

1092.—DISINFECTION: THE HG Cl_2 SPRAY AND THE SO_2 PROCESS.—"T. L." writes:—"Will you please inform me what is meant by disinfection of rooms by (1) the Hg Cl_2 spray, and (2) by disinfection of rooms by "the SO_2 process?"

Answer.—(1) We have described in answer to query 1095 in this issue the method of disinfecting rooms by spraying, which is carried out by means of the Equifex sprayer. The term "Hg Cl_2 spray" refers to the application of perchloride of mercury or corrosive sublimate, as it is otherwise described, as the particular disinfectant with which the vessel is charged, the liquid being sprayed on the walls and ceilings after cases of infectious disease. (2) The "SO_2 process" is the disinfection of rooms by sulphurous acid, or more accurately, sulphur dioxide, which is a gas formed whenever sulphur is burnt in air or oxygen. This process is one of the most common, by reason of its cheapness and the ease with which it can be generated. The usual way is to take some roll sulphur, about 1½ lb. being allowed for every 1000 cubic feet of space, seal up the room by pasting paper over all crevices which would permit the escape of the gas, light the sulphur in an iron vessel under which is placed a pail of water to prevent the risk of fire, and let it burn. Sulphur candles made specially for the purpose, as Kingzett's patent sulphur fumigating candles by the Sanitas Company, Limited, are a convenient method of carrying out the process. Another and very convenient form is to procure it in a liquid form put up in cylinders as prepared by Messrs. A. Boake, Roberts, and Co., Stratford, London, E.

1093.—COMMON LODGING-HOUSE: BEERHOUSE.—"M. O. H." writes:—"Would a beerhouse letting lodgings to the poorer classes for short periods and who are strangers to one another inhabiting one common room be considered a common lodging-house, and thus come under the control of the bye-laws and the supervision of the Medical Officer of Health? Or would it be exempt from such control and be under the inspection of the police only?"

Answer.—There is no statutory definition of a common lodging-house. Whether a house is kept as a common lodging-house is in every case a question of fact for the determination of the justices. In Langdon *v.* Broadbent, 42 J.P., 56, 67, it was held that evidence that hawkers, itinerant picture-frame makers, chairmakers, musicians, bone gatherers, and persons suspected of begging, resorted to a house for lodgings and had their meals in the kitchen at the same time, paying 6d. per night each, is sufficient to establish that the house is a common lodging-house requiring to be registered under the Public Health Act, 1875. The fact of the house being kept as a beerhouse does not exempt it from registration and from the operation of the bye-laws as to common lodging-houses, and from the information furnished by our correspondent we should say that there is evidence that the house is kept as a common lodging-house, and should be made subject to the operation of the bye-laws relating thereto.

1094.—SEWERAGE: NUMBER OF HOUSES WHICH MAY BE CONNECTED TO 6IN. AND 9IN. DRAINS.—"T. L. H." writes:—"(1) For what number of houses will a 6in. sewer be sufficient when laid with a fall of 1 in 60, the houses in question containing two rooms on the ground floor and one w.c. of the slop-water pattern?

(2) What number of the same class of house will a 9in. sewer take? In both instances the sewers will be on the separate system, the existing sewers and drains being left to take surface water from backyards, streets, and fall pipes from the roofs."

Answer.—There are many formulæ and tables which are used for calculating the capacity and discharge of sewers. For the purposes of our correspondent we should recommend him Spinks' "House Drainage," 5s. The author has therein given a table showing the maximum quantity of sewage to be removed per minute from various types of houses and also rainfall to determine sizes of drains. Thus the maximum flow of sewage, exclusive of rainfall, to be provided for in a house with two rooms on the ground floor is calculated to be 2 cubic feet (or 13 gallons) per minute; the discharge from a 6in. pipe running full at an inclination of 1 in 60 is 294 gallons, and the number of houses which may be connected to such a drain is therefore 294 ÷ 13 = 22·6, say, twenty-two houses. (2) A 9in. sewer laid at an inclination of 1 in 60 discharges 139 cubic feet, or 866 gallons per minute. Taking therefore as before the maximum discharge from one house as 13 gallons per minute, the question becomes 866 ÷ 13, which gives 66·6 houses as the number which may be drained into a 9in. sewer laid at an inclination of 1 in 60, when all the rainfall is excluded from the sewers. The correspondent will also find Crimp's "Tables and Diagrams for Use in Designing Sewers and Water-mains," price 10s. 6d., of great assistance to him. Either of the books named may be obtained from the Sanitary Publishing Company, 5, Fetter-lane, E.C.

1095.—Disinfecting Rooms by Spraying: Principles and Method.—"J. W." writes:—"Will you please describe for me the principles and method of disinfecting rooms by sprayers, and the cost of same?"

Answer.—The disinfection of rooms after cases of infectious disease by spraying by means of a specially constructed apparatus, of which the Equifex sprayer (Geneste Herscher pattern) is the best known, the sole licensees and makers of which are Messrs. J. Defries and Sons, 147, Houndsditch, London, E.C., is held by many bacteriologists of repute to be much superior and more reliable than fumigation by sulphurous acid, chlorine, or bromine. The Equifex disinfectant sprayer consists of a strong metal reservoir, into which liquid disinfectant is poured; a hand pump by which air is compressed above the disinfectant; and extension tubes which may be of any length for projecting the spray against the surface to be disinfected. By working the hand pump the spray is formed and delivered against the walls of a room at a rate which can be controlled at will by the manipulator by turning an air cock. The fineness of division of the liquid enables the work to be done with the minimum amount of disinfectant. Any liquid disinfectant may be used for the purpose, and it is asserted that its use effects a considerable economy of expense and money over other methods. The cost, of course, varies with the disinfectant used. If perchloride of mercury, 1 in 1000 solution, is used, it is found that an ounce of salt disinfects more than 3000 square feet of surface. The time occupied in the operation is about an hour per 1300 super feet. This system of disinfection is adopted by the Paris Municipality in lieu of fumigation, and it is claimed that the occurrence of house epidemics has practically ceased through the prompt and rigid use of it, and epidemics are got under and arrested in a considerably shorter period than has previously been possible. It is asserted that fumigation by sulphurous acid is usually impracticable through the difficulty of keeping the rooms air-tight during the operation, and objectionable through entailing the disuse of the room for one or even two days. The cost of the Equifex sprayer is from £8 to £16, particulars as to which may be obtained from the makers.

1096.—Dismissal of Sanitary Inspector: Irregularity.—"Inspector" writes:—"The Rural District Council of X, without any reason, give their Sanitary Inspector three months' notice to terminate his appointment. The appointment is held subject to the approval of the Local Government Board, who pay half the salary. The Council in November last reappointed the officer for three years, which was confirmed by the Local Government Board. (1) Can the Council dismiss the officer without the sanction of the Local Government Board? (2) Can the notice be given any time, or should it not be given at Quarter-day? There was no stipulation on appointment. (3) What course should the Inspector take? (4) The officer holds the post of Highway Surveyor, from which he has been dismissed. If the Local Government Board refuse to sanction dismissal from sanitary appointments, and if the officer states he is willing to hold one without the other, would the Local Government Board approve?"

Answer.—(1) No. An Inspector of Nuisances cannot be removed under such circumstances from his appointment without the assent of the Local Government Board, as prescribed by Article 10 of the Local Government Board's General Order of the 23rd March, 1891. (2) It appears to us from Article 12 of the order referred to, that the Sanitary Authority are required to give six months' notice for the determination of his engagement. (3) The Inspector should address a letter on foolscap paper to the President of the Local Government Board, under cover directed to the Secretary of the Board, giving all the facts of the case as concisely and fairly as possible, and if, as so often happens, the Inspector is being treated unfairly in consequence of the impartial discharge of his duties, this should be narrated and the powers of the Local Government Board to annul the notice of dismissal invoked. (4) The Local Government Board have no control over the office of Highway Surveyor, and the fact that he has been dismissed from the Surveyorship would not affect their decision. The officer may hold the office of Inspector separately from the office of Surveyor. We shall be pleased to be furnished with further particulars, and assist our correspondent if desired.

Contracts Open.

The dates given below are the latest up to which tenders can be received.

Burghead (Scotland).—May 30th.—Drainage of Cemetery.—Mr. Geo. D. Gordon, clerk to the Committee.

Consett (Durham).—May 30th.—Drain, &c.—Mr. William S. Shell, M.S.A., architect and surveyor, Taylor-street, Consett.

Boston (Lincs).—June 1st.—Drain Works.—Mr. C. G. W. Phillips, C.E., Witham Office, Boston.

Knaresborough.—June 1st.—Sewers.—Mr. George Wilson, C.E., surveyor.

Southend-on-Sea.—June 1st.—Sewer.—Mr. Alfred Fidler, A.M.I.C.E., borough surveyor, Clarence-road, Southend.

Blaydon-on-Tyne.—June 2nd.—Scavenging.—The Surveyor, Council Offices.

Trealaw (Wales).—June 3rd.—Sewers, &c.—The Surveyor's Department, Council Offices, Pentre, R S.O., Glam.

COMPETITIONS.

Castletown (Ireland). — June 9th. — Sewerage Works.—The Guardians invite tenders from compe t engineers for preparing plans, specifications, and estimates for a scheme of pipe sewerage works for the town of Castletownbere. Sealed tenders, endorsed "Tender for Plans—Sewerage Works," will be received by Mr. M. J. Donovan, executive sanitary officer, Board-room, Workhouse, Castletownbere, up to twelve noon on June 9th.

Vacancies.

ASSISTANT ENGINEER (HOUNSLOW, June 1st).—For the Heston and Isleworth Urban District Council. Salary, £140 per annum. Mr. W. Augustus Davies, A.M.I.C.E., engineer and surveyor, Town Hall, Hounslow, W.

BUILDING INSPECTOR (SWINDON, June 7th).—For the Swindon New Town Urban District Council. Salary, £130 per annum. Mr. Henry Kinneir, clerk, Public Offices, Swindon.

CLERK OF WORKS (Knutsford, May 31st).—For the Bucklow Rural District Council. Salary, £2 per week. Mr. George Leigh, clerk, Union Offices, Knutsford.

CLERK OF WORKS (WARLINGHAM, SURREY, June 14th).—For the Croydon Town Council. Salary, £4 4s. per week. Application forms to be obtained at the Town Clerk's Office, Croydon, and to be sent to Mr. E. Mawdesley, town clerk, Town Hall, Croydon.

COUNTY SURVEYOR (LEWES, June 24th).—For the Roads and Bridges Committee of the East Sussex County Council. Salary, £400 per annum. Mr. F. Merrifield, clerk, County Hall, Lewes.

ELECTRICAL ENGINEER (LONDONDERRY, May 31st).—For the Corporation. The salary will be at the rate of £160 per annum. Sir R. Newman Chambers, town clerk, Guildhall, Londonderry.

GASWORKS MANAGER.—Mr. W. Selby, secretary, Gasworks, Yarm, Yorks.

INSPECTOR OF NUISANCES, &c. (UPTON-UPON-SEVERN, June 1st).—For the Rural District Council. The salaries will be as follows:—Inspector of nuisances, £100 per annum; sanitary surveyor, £15 per annum; and inspector of canal boats, £2 per annum. Mr. George Powell, clerk, Upton-upon-Severn.

INSPECTOR OF NUISANCES (WILMSLOW, CHESHIRE, May 28th).—For the Urban District Council. Mr. William Cobbett, clerk, Wilmslow.

INSPECTOR OF WORKS (LONDON, N.W., May 27th).—For the St. Pancras Vestry. Salary, £130, rising £10 annually to £150 per annum. Application forms to be obtained of Mr. C. H. F. Barrett, vestry clerk, Vestry Hall, Pancras-road, N.W.

SANITARY INSPECTOR (CAMBRIDGE, May 31st).—For the Town Council. Salary, 35s. per week. Mr. J. E. L. Whitehead, town clerk, Guildhall, Cambridge.

To Medical Officers, Surveyors, Sanitary Inspectors, &c.—High-grade Cycles at reasonable prices for prompt cash and on the GRADUAL PAYMENT SYSTEM. Catalogue post free.—MELROSE CYCLE COMPANY, Coventry.

INSURANCE.

"The Purification of Sewage & Water."

By **W. J. DIBDIN**, F.I.C., F.C.S., &c., late Chemist to the London County Council.

PRICE 21s. Net.

(With numerous Illustrations and Diagrams.)

THE SANITARY PUBLISHING CO., LTD., have much pleasure in announcing the publication of a new and important work, entitled "THE PURIFICATION OF SEWAGE AND WATER," written by Mr. W. J. DIBDIN, F.I.C., F.C.S., &c., late Chemist to the London County Council.

The subject matter, in a modified form, has appeared in *The Sanitary Record*, and the articles aroused so much interest, that a demand at once arose for publication in book form, and it is in response to this demand that a first edition of 1000 copies has been prepared.

In view of the terrible typhoid epidemic at Maidstone, and the liability of the great centres of population to similar outbreaks, a work of this nature, which deals most exhaustively with the subject of sewage and water purification from the very latest scientific standpoint, cannot but be most opportune. There is not a Local Authority, in fact, that can afford to be without it, and the publishers venture to predict its speedy adoption as a standard work among public health authorities at home and abroad.

SYNOPSIS OF CONTENTS.

Introduction.—Chapter I. Foul Matters, their Character and Composition. Combustion and Oxidation. Putrefaction. Bacteria.—Chapter II. Antiseptics, or Preservation for Limited Periods. Bacteriological Methods.—Chapter III. Various Proposed Methods of Artificial Purification. Precipitation.—Chapter IV. Experiments at Massachusetts, London, and Sutton. —Chapter V. Nature's Method at Work. New Departure at Sutton, Surrey. The Septic Tank System at Exeter.—Chapter VI. Analytical Methods Suitable for Watching the Progress of the Purification of Sewage.—Chapter VII. Interpretation of the Results of Analyses.—Chapter VIII. The Absorption of Atmospheric Oxygen by Water.—Chapter IX. Suggestions for Sewage Works Conducted on Biological Principles.—Chapter X. The Purification of the Thames.—Chapter XI. Ventilation and Deodorisation of Sewers —Chapter XII. The Filtration of Potable Water.—Chapter XIII. The Character of the London Water Supply. Microscopical Character of the Suspended Matters. Bacteriological Examination. The Effect of Softening the Present Supply.

PRESS OPINIONS.

"The book is one that no engineer engaged on works of water supply and drainage can afford to omit from his library, and a book that with all its technical features would none the less afford valuable education to many county and district councillors."—*Western Morning News.*

"The book will well repay careful perusal. Every health officer should possess it."—*British Medical Journal.*

"The experiences and researches of Mr. Dibdin in respect to the treatment of sewage are so widely known . . . . that the publication of the present work will be hailed with satisfaction, and should be followed by the most valuable practical results . . . . packed with facts and technical information . . . . would be of the utmost value if it contained no more than the full description of the process (and its results) now in use for purifying the water of the river Thames."—*Newcastle Daily Chronicle.*

"The author's long experience in dealing with problems relating to the disposal of sewage in London, in his capacity of chemist to the London County Council and to the late Metropolitan Board of Works, and the success which has met his efforts, fully justify the issue of this record of his experiences and observations. . . . The book is such a readable one, and the subject so interesting to all dwellers in this city, where not only our system of sewage disposal is at fault or insufficient, but even our atmosphere is polluted, that one is tempted to continue quoting from it. Our city fathers will do well to give it a careful perusal."—*Glasgow Herald.*

"A most interesting and welcome contribution to our information upon a problem of world-wide importance. The volume in appearance and finish is calculated to do credit to the Sanitary Publishing Company . . . . is or a most readible character from beginning to end."—*The Chemical Trade Journal.*

"Pure sewers nnd pure water supplies are the objects aimed at in the publication of this valuable work. The author is well-known of an authority on the subject of which he writes, and has done splended work in connection with the purification of the Thames and the treatment of London sewage.—*Liverpool Daily Mercury.*

"The book is excellently got up, and will be read by all interested in sanitary questions. It is so clear and popular in style that the ordinary non-scientific reader can have no difficulty in following Mr. Dibdin's clear account of another application of bacteriology to the problems of life and health."—*Leeds Mercury.*

"A most interesting work . . . sure to be held in estimation by all those interested in sanitary science. It is an accurate and valuable gauge of the present position of matters relating to the more pressing questions of modern hygiene."—*The Lancet.*

THE

PENSION QUESTION SOLVED

How Public Health Officials may Secure a Pension in Ten, Fifteen, or Twenty Years of from £10 to £100 or more per annum.

This question is admittedly one of paramount importance to all Public Health Officials who are dependent upon their own exertions to provide for the future, and one which has for some time exercised the minds of those who are so situated. It is therefore a matter for general congratulation that a satisfactory solution of the problem has been arrived at. Those who wish for particulars are invited to fill up and return to the undersigned the subjoined form, when the fullest information will be forthcoming from a source which is highly approved and recommended by THE SANITARY RECORD.

Please inform me what Annual deposit would be required to provide a Pension of £_____ per annum in _____ years, and what sum my family would secure in the event of my decease previously; also any other investment advantages offered on my surviving.

Notes.

The Slight to the General Medical Council.

THE intimation by the Earl Marshal, that he was unable to accede to the request of the General Medical Council for an allocation of seats in Westminster Abbey on the occasion of Mr. Gladstone's funeral, on account of limits of space, undoubtedly came as a very painful surprise to the members of that august body. They felt, and we think rightly felt, that the refusal indicated a lack of the recognition to which the Council is entitled, as representing one of the great learned professions. When not even the president of the Council was invited, and

ample provision was made for the representatives of many bodies not of the chief importance, it could hardly be construed as other than a slight to the profession. It is a question of principle. The medical profession surely occupies a place of sufficient consequence in the national polity to be entitled to representation in all national functions; and the Council was therefore perfectly right in insisting that steps should be taken to ensure in future such recognition in State ceremonials as accords with its status and dignity.

The Question of Foreign Immigration.

There has been much talk for a number of years about the necessity for taking steps to restrict the tide of immigration of destitute aliens, which year by year floods our shores with a most undesirable class of population; but our legislators have been slow to give up the name which Britain enjoys of offering a free asylum to all the world. Our proverbial hospitality may, however, be carried a point too far, and within recent years this has been increasingly felt to be the case. The tide of foreign immigration has been steadily growing in volume, and has at last reached the dimensions of a serious evil. During the last seven years no less than 40,000 aliens have settled in this country, and the worst of it is that not only are the immigrants usually of the lowest type, but they congregate in particular localities—notably in the East End of London, where four-fifths of them settle—and they produce a very marked effect in lowering the standard of wages, lowering the standard of life, and helping to foster the growth of slums, all to the detriment of our own working population.

The Aliens Bill.

Other countries have long adopted legislative measures for their own protection, and now there is the prospect of our doing likewise. The Aliens Bill, which passed its second reading by a large majority in the House of Lords last week, is designed to regulate the immigration of destitute aliens by providing that at certain ports, which are to be designated by Order in Council, the Inspectors of the Board of Trade may board any vessel bringing immigrant passengers, and prohibit the landing of any alien who, on inspection, appears to be an idiot, insane, a pauper, or likely to become a public charge, or who is "suffering from any dangerous, contagious, or infectious disease." Such persons shall be sent back to the port whence they came at the expense of the owners of the vessel. This is not the place to dwell on the social or economic aspects of the question, but all sanitarians will at once note with especial interest the provision which relates to persons suffering from infectious disease. The Russian and Polish Jews who crowd yearly into the East End of London, and who constitute the greater proportion of the foreign immigrants, usually belong to a class that is singularly destitute of the most elementary notions of hygiene. They form a real element of danger to the people among whom they settle, both through overcrowding and through their insanitary habits of life; and it is only fair to our own countrymen that they should be protected from this danger. The Bill is not a Government measure, but it has the support of the Government, and though it has been subjected to hostile criticism in some quarters, the principle on which it rests is generally admitted to be beneficial, and there seems to be little doubt that the Bill will, in some shape or form, become law at no distant date.

The Plague in India.

Though there is an absence this week of precise information regarding the progress of the plague in India, there are indications that it is continuing to subside, and that the state of unrest among the natives is quieting down. One thing to be regretted is that the Plague Committee in Bombay has lost the able services of Sir James Campbell, who has for so long been the guiding spirit of its policy. After nearly thirty years of work in the Bombay Presidency, he retired from the service at the end of April. The value of Sir James Campbell's labours in Bombay, and in particular of the work he has carried through as chairman of the Plague Committee, it is difficult for us on this side to estimate at its true worth; but we may take the testimony of the *Times of India* as reflecting the best opinion of Englishmen in Bombay when it speaks of him as "one of the most high-minded and faithful servants that the State has ever had." He has been at the head of affairs during a singularly trying crisis in the affairs of the city, and how he has discharged his responsibilities we may measure from the words of Lord Sandhurst, the Governor, shortly before leaving India. "Whatever criticisms," he said, "may have been passed upon the Plague Committee, of this I am confident, that no more disinterested body has endeavoured to serve you, and Sir James Campbell and his colleagues are entitled to the greatest gratitude."

The Tenure of Medical Officers in the Highlands.

When we wish for examples of high-handed action on the part of Local Authorities towards their officials, we not infrequently have to look, not to the great centres of population, but to outlying districts and small rural parishes. The Parish Council of Stronsay, in the Highlands, recently gave notice of dismissal to their Medical Officer, and declined to furnish him with any reasons for their action. We are not acquainted with the precise circumstances and the merits of the case, but it seems on the face of it to have been a somewhat tyrannical proceeding. The Local Government Board requested the Parish Council for some explanation; but the point for Medical Officers to note is that in law the Parish Council were strictly within their rights, for the Lord Advocate stated in Parliament that he was not aware that the Medical Officer who was dismissed had any right of appeal in the matter. That may be so, but none the less does it seem to us a matter for reprobation that petty Local Authorities should take such a view of their powers, and of their duties towards their servants.

More Figures at the Water Commission.

The London County Council has a good champion of its views in Sir Alexander Binnie. There appears to be no limit to the facts and figures he is able to bring to the notice of the Royal Commission in advocating the obtaining of fresh sources for

supplying the metropolis with water. At the last sitting he set himself to prove that it would really be cheaper to go to Wales for these than to establish any more immense reservoirs near the banks of the Thames. His plan is to take 121 million gallons per day from the Yrfon and 44 millions from the Towy. The works in Wales—headworks and reservoirs—would cost £2,190,000. From these an aqueduct of 162 miles would have to be constructed to convey the necessary 200 million gallons per day to Elstree, where the terminal works would be situated. The aqueducts would cost £7¾ million, and filters and other works at the metropolitan terminus would require some £2,413,750. Parliamentary and law charges would swallow up three-fifths of a million, or a total of £14,112,000 for the entire works. In the opinion of Sir Alexander Binnie the Thames could not yield, at a reasonable cost, 147 million gallons in addition to the 185½ million gallons already sanctioned. To erect reservoirs at Staines to supply 300 million gallons per day would cost £15 million. These figures are "tall," but if either of the schemes are carried out we fancy they will be found under rather than over the actual cost. Yet something will have to be done.

The Building Catastrophe at Westminster.

The length of the inquiry and the serious nature of the verdict of the jury have caused a large share of public attention to be directed to the collapse of a large building at Westminster. Every one must deeply deplore the fatalities resulting from the calamity, but it seems that it was only something of the kind that could really demonstrate the unsatisfactory state of the law with regard to the erection of new buildings in the metropolis. Theoretically, a constant inspection should be made by the "District Surveyor" as a structure proceeds. But this officer occupies a curious position. Appointed by the Home-office, that Department has no control over him; he passes plans, for which he receives fees, and reports on them to the County Council or the Vestry. He may give directions or order modifications, but he has no authority to enforce them. Further, it appears that he has no power over the internal construction of a building; in fact, his position is most unsatisfactory, both to himself and to the Authorities he is supposed to represent. "What wonder, then," asks a writer in the *Pall Mall*, "if jobbery, scamped work, and rotten buildings result?" The County Council and Vestries should join hands in demanding a reform. Would it not be better if the Local Authority were made responsible for all new buildings within its jurisdiction?

The Vaccination Bill.

To read the statements of some persons with reference to the Government Vaccination Bill, a stranger would be inclined to think an attempt was being made to inflict some great hardship upon the community, or that "vaccination" was merely an experiment, and that a dangerous one. The truth is, some people have conceived a fanatical antipathy to Jenner's great preventive force, and will not admit the possibility of it being a blessing to the community. Hence we have a meeting or conference called, to which it is carefully arranged opponents of the Bill shall be the predominant influence, and then we are told the Poor Law Guardians of the country are "emphatic" in their "disapproval" of the measure. All this kind of thing is easily worked up, but we think it will have but little influence upon the Government. It is "too blatant," for whatever the Bill had been, the same people would have condemned its proposals. That there may be weak points in the Government propositions is possible; but the main object is to ensure the protection of the community from an insidious disease. Up to the present vaccination holds the field as the best protection against small-pox, and until the "anti" can produce a better the Authorities are justified in their desire to secure a more universal adoption of this "preventive."

A Charge of Heresy at Bristol.

Our attention has been directed to a recent utterance of Dr. Davies, the well-known Medical Officer of Health for Bristol, in which he sets forth some "unorthodox" views on the question of sewer ventilation. As a rule we are not much concerned when a man is accused of heresy; for it simply means that he has had the courage to express an opinion he has formed on a particular point, and which does not not quite coincide with generally-accepted theories. But, after all, we like to have a reason given for the "faith" proclaimed. Up to the present sanitarians, and especially those with special experience in sewerage work, strongly advocate the placing of ventilators throughout the line of sewers. Generally speaking this advice is followed; and, in fact, some difficulty would be experienced in persuading a Local Government Inspector to recommend the passing of any new scheme without them. But at Bristol this has not been done, and several inhabitants have recently pressed the Authorities to bring their drainage system into line with other usage. Naturally the Council seeks the advice of its Medical Officer, and his reply is, "Don't." Pressed for a reason, he is reported to have said that "He considers the ventilation of public sewers is unnecessary and dangerous." Now, this "pious opinion" may or may not be sufficient for the Bristol Councillors; but something more will be required by others before they accept this new doctrine and throw away the old dogma. Still, we are willing to be taught; and if Dr. Davies will go a step further, and give us the data upon which his opinion has been formed, we will gladly open our columns to him, in order that others may be led into the "new light" that he has found.

The Crypt of St. George's, Southwark.

Since we drew attention to the unsatisfactory condition of the Parish Church of St. George's, Southwark, an official inquiry has been held by a representative from the Home-office, and his report will shortly be made public. The crypt, however, formed the topic of a very heated discussion at the last meeting of the Vestry, one or two features of which deserve special attention. Nothing can be clearer than the unfair treatment of Dr. Waldo by some members of the Vestry. After the visit of the representative of the Home-office had been reported, the Chairman innocently asked the Medical Officer if he had anything fresh to place before the Vestry, to which

Dr. Waldo made the significant reply: "I am not allowed to present any report to the Vestry until it has been before the Health Committee." Later in the evening the Chairman intervened in the debate, and made a most bitter attack upon Dr. Waldo, making charges against him, which the doctor emphatically and categorically refuted. Notwithstanding this, the Chairman persisted in his statements. Happily, at least one of the members had the courage to protest against his ungentlemanly conduct.

An Unworthy Attack.

Our readers will readily understand the position of affairs. A Medical Officer has his attention called to what is believed to be a nuisance. In strict accord with the duties of his office he makes an investigation and gives a report. His experience and training enable him to appreciate the possible dangers arising from a continuance of the nuisance, and he is prepared to make recommendations for its abatement. But the Vestry declines to hear him, and, worst of all, the Chairman—who at least should be impartial, and give some amount of protection to the officers against attacks they are prohibited from repelling—forgets himself in such a manner as to outdo all others in bitterness of speech and unworthiness in the method of attack. We are glad to know that the incident is almost without precedent in the annals of local administration. At the same time it is intolerable that a conscientious public officer should be subject to such treatment because he seeks the well-being of his district in preference to currying the favour of a partisan Vestry.

Notification at Melton Mowbray.

We have before us the report of the proceedings at the last meeting of the Melton Mowbray Urban District Council. From these we gather that Melton occupies a peculiar position. In all the surrounding districts the Notification Act has been in vogue for some time, but for some reason the Melton Council had refused to follow the lead of its neighbours. Time after time the Medical Officer had urged its adoption, but without effect. At the meeting under notice a petition was received from doctors of the town pressing the Council to reconsider its decisions, and setting forth the various advantages to be gained through notification. One of the members backed up the petition in a common-sense, practical speech, in which he showed the benefits adjoining districts derived from the adoption of the Act, especially with regard to dairy produce, their principal industry. It was, however, of no avail. A majority of the Council refused to grant the prayer of the petition. It might, they said in effect, be all very well for the Act to be adopted by rural districts, for milk vendors in towns would not buy their milk from farmers in districts where notification was not carried out. Melton was a town, and therefore did not need such a certificate. But we have an idea that a large number of pork pies are supposed to come from this place, and it is well that retailers of these should understand that Melton Mowbray declines to protect itself from infectious disease, and that there is no guarantee that these pies are not produced on premises where such disease abounds. Eaters of pork pies are just as deserving of protection as consumers of milk, and perhaps those who manufacture them will see the wisdom of pressing the Council to grant the prayer of the doctors. One of the opposing speakers admitted that over £30,000 had been spent in sanitary improvements, yet he opposed the annual outlay of about £2 in protecting the people from the spread of disease. The paltry half-a-crown fee appears to be the bugbear, and sooner than spend it they would run the risk of an epidemic.

Municipal Dwellings for London.

Remedies for metropolitan overcrowding are only to be found in municipal dwellings, and it is satisfactory to find that the attention of the London County Council has at length been drawn to the inoperativeness of its past policy in this respect. A subcommittee of the Housing of the Working Classes Committee of the Council has for some time been engaged in reviewing the position, and a report on the subject may shortly be expected. Only by municipal competition in rents will the tumbledown tenements of East London be let at their proper value, and the necessities of the working classes to live near their labour will not be made the opportunity of rapacious landlords. But it is well known that the London County Council has failed miserably in its dwellings policy. Buildings of an unnecessarily expensive and ideal character have been erected in accordance with the dictates of Councillors with fads, and the natural result is, that bound with iron statutory obligations as well, the Council has found its dwellings a terrible financial burden, while the tenants themselves have not reaped the advantage which they ought to have reaped, from the fact that the municipal authority of London can borrow its money so cheaply, and have had to pay rents as high as they would in the case of ordinary dwellings. In this way the policy of the Council has defeated its own end, for it cannot lower rents and it cannot increase the accommodation by further buildings, and the municipal housing work of London has been at a standstill for some years.

The Overcrowding Question.

In East London the question of overcrowding is coming to the front in an unmistakeable manner, most of the Local Authorities showing a disposition to turn their attention to it in a practical manner. This is a subject which involves the problem of the hour—how to house the ever-increasing population of our large towns and cities. So far as the East End is concerned the difficulties are enhanced by reason of the local feature of a foreign element, which is every year becoming more and more pronounced. Various influences are at work which tend to raise rents and foster the consequent overcrowding, and startling statements of cases met with in the slums of St. George's (East) and Whitechapel—the home of the foreign immigrant—have arrested the attention of the Authorities. The remedy appears to be in the hands of the municipality in providing proper housing accommodation. Fines and imprisonment are useless, the efforts of the Sanitary Inspector to keep the surplus population moving supply no solution of the problem, and it is absurd to expect people to pay the exorbitant rents demanded.

THE CHEMICAL AND BIOLOGICAL ANALYSIS OF WATER.

By T. H. Pearmain and C. G. Moor, M.A.

Members of the Society of Public Analysts. Authors of "Applied Bacteriology;" "The Analysis of Food and Drugs," &c.

(*Continued from page* 559.)

MICROSCOPIC EXAMINATION OF SUSPENDED MATTERS.

Respecting the information that we may gain from a microscopic examination of suspended matters, it must be remembered that, while we may sometimes find such substances as epithelial scales, undigested muscular fibres, and the like, which may be positive evidence of pollution, yet in most cases such substances will be filtered out of the water if it has passed through earth; and as well water is by far the most frequent water sent to the analyst, he will only occasionally derive assistance from the microscopic examination of suspended matter.

To examine water for suspended matters it was generally the custom to set aside about 200 c.c. in a conical glass, and after the suspended matters had settled out to examine some of the sediment under the microscope. A more efficient plan than this is the use of the "micro-filter" described by Dibdin (*Analyst*, 21, 2), by which means the whole of the suspended matter may be rapidly removed from a considerable volume of water in a short time, and a tolerably exact estimation of its quantity arrived at. Dibdin first filters about 500 c.c. of the water to be examined through hardened filter-paper, and then washes the suspended matter retained by the paper into his "micro-filter," which is a narrow tube plugged at the smaller end with a mixture of clay and kieselguhr.

As ordinary filter-paper is made from linen fibre, one must be prepared to find linen fibres in water that has been examined in this way.

The *mineral matters* that may be found in water are sand, clay, oxide, &c., which will settle out on standing, and are of no hygienic importance.

The *organic matters* may be living organisms, animal or vegetable, together with animal and vegetable *débris*.

For the sake of convenience we divide them, as far as possible, into classes, giving their significance where it is known. Some of these—for example, desmids and diatoms—are found in the purest mountain water, and are rather evidence of purity than the reverse; and, speaking generally, the same may be said of most of the chlorophyll-containing organisms. *These remarks do not apply to sand-filtered water*, which ought to be *entirely free* from all kinds of suspended matter, and the determination of suspended matter, as suggested by Dibdin, is of itself a good means of keeping a check on the proper working of filter-beds.

ALGÆ.

Amphiprora ornata (1).

Amphora ovalis (2).

Both these organisms are diatoms. They contain chlorophyll, and are found in ponds and streams.

1

2

Asterionella formosa.—This organism belongs to the diatoms. It contains oils or fats in its ectoplasm, and produces a disagreeable fishy taste and smell in water. It is a rod-shaped body, somewhat dumb-bell shaped.

3

Beggiatoa alba (3).—This organism is characteristic of decaying vegetable or animal matter. It is distinguished by the bright grains (said to be sulphur) visible in the cells. It is common in sulphur springs, and so prevalent in polluted water as to have earned the title of the sewage fungus. It contains no chlorophyll.

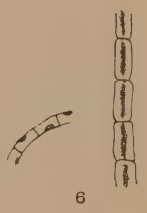
Cœleospherium (4).—This organism is mentioned by E. Waller, Board of Health Reports, Brooklyn, as producing a disagreeable smell in water.

4

5

Cladothrix dichotoma (5).—This alga is found in running or stagnant water. The filaments are harsh to the touch. It is common in the refuse water from sugar factories. In Russia it often occurs in town water supplies. It grows readily on the surface of putrefying animal or vegetable matter immersed in water. It has an avidity for iron, and sometimes forms obstructions in iron pipes.

Confervæ (6).—These are fili-form algæ, which are widely distributed in all ponds, rivers, and reservoirs, being especially abundant near the margins.



6

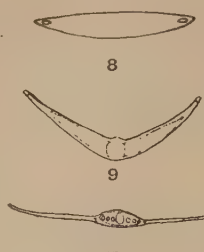
7

Cladothrix Kuhniana (7).—This organism is common in running or stagnant water that is rich in organic matter. The threads are motile, and in their younger stages are grouped into little patches. They have a greenish or brownish colour, and impart the same tint to the water. If a reservoir is infected with them, large quantitities of water may be deteriorated in a short time.

Closterium ensis (8).

Closterium dianæ (9).

Closterium rostratum (10).



These organisms are among the commonest of the desmids, and are often found in water supplies. Their presence is not objectionable, as they can only live in pure water which has plenty of air and sunlight. They all contain chlorophyll.

Gomphonema acuminatum (11).

Gomphonema capitatum (12).

Occur chiefly in pond water. They contain chlorophyll, and belong to the diatomaceæ.

Melosira granulata (13).—This diatom forms long filaments in water, and on account of oil or fats in its ectoplasm produces disagreeable grassy taste and smell in water supplies.

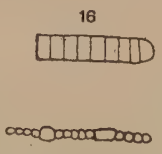
Navicula radiosa (14).

Navicula viridis (15).

These diatoms are motile, and contain chlorophyll of a dark-yellow colour.

Oscillaria (16).

Nostoc (17).



These organisms, which are anabœna, form blueish-green or brownish patches. They are chiefly found in stagnant water, and as they produce a disagreeable smell in water their presence is very objectionable on this account, and because they indicate the presence of a large amount of organic matter.

Protococcus viridis (18).—This is a very common inhabitant of streams and rivers, and probably assists in its self-purification. It propagates by fission, and is generally seen in groups of four.

Scenedemus (19).—This organism is common in ponds, but does not appear to possess any hygienic importance. It contains chlorophyll.

Spirogyra (20).—This organism contains chlorophyll in spiral bands and starch granules. It is a common inhabitant of ponds and streams.

Staurastrum gracile (21).—This organism is one of the commonest desmids, and its presence in water is not objectionable, in fact it is stated that it can only live in pure water which is well aërated and exposed to the light.

Stauroneus phœnicenteron (22).

Synedra pulchella (23).

Synedra ulna (24).

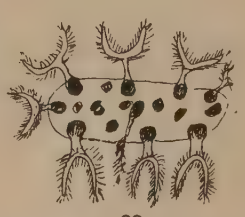
Both these diatoms are said to cause a disagreeable grassy taste and smell in water.

CŒLENTERATA.

Hydra vulgaris (25).—This organism is characteristic of stagnant water.

Polyps, *sertularia* (26) and *campanularia* (27).

Polyzoa, *lophopus* (28), *cristatella* (29).



These are low animals allied to the hydra, corals, and anemones.

(*To be continued.*)

RECENT DISINFECTION BY CHLORINE COMPOUNDS.

By S. RIDEAL, D.Sc. (Lond.)

DISINFECTION by chlorine, or its compounds, has always maintained a certain degree of favour on account of its efficiency and cheapness, but the objectionable odours and corrosive action of the class, the decided unpopularity of chloride of lime,* their chief representative, has led to their being overshadowed of late years by a multitude of coal-tar compounds, most of them decidedly not justifying the statements or testimonials with which they are issued. The faults of the phenol group have led to a recent revival of chlorine disinfection, as exemplified in the hermite process, electrozone, chloros, and chloride of lime itself. The reason of the general dislike to chloride of lime is not far to seek. Apart from the odour, which to many people is singularly disagreeable, its cheapness, and the lumpy character produced by its deliquescent nature, had caused it to be thrown in shovelfuls on iron gratings, which it rusted, or down the metal syphons of water-closets, which, whether lead or iron, it often pierced, and then to be washed away without dissolving, and therefore with only imperfect disinfectant effect. Disinfection carelessly or insufficiently done is worse than no disinfection at all, as it conveys a sense of a false security. The fact that chloride of lime requires to be well stirred with water before using, and that it deposits about 40 per cent. of insoluble matter, chiefly lime, has led to the re-introduction of hypochlorite of soda, which gives no such insoluble deposit. Each of these compounds is useful in its own way.

The Hermite process, in which electrolysed sea water, containing hypochlorous compounds, is mixed with sewage, was subjected to trial at Worthing in 1894, with results which provoked considerable controversy.

In an elaborate report by Roscoe and Lunt, of experiments at Worthing,† the main conclusions are that electrolysed sea water, when dilute, is very unstable, and requires to be used soon after preparation, that it fails to dissolve paper or solid fæces, or to sterilise the interior of the latter; that it is an excellent deodoriser, but is not by itself applicable as a process of sewage purification.

A hermite patent (Paterson and Cooper, 2197, 1896) proposes to prevent the loss of strength by adding a small proportion of soda or milk of lime. Crawford (14,852, 1896) strengthens the liquid by cooling during electrolysis. The *Lancet* found that full strength hermite fluid containing ·02 per cent. available chlorine was fatal to diphtheria and cholera bacilli.

"Electrozone" is a liquid similar to the Hermite prepared according to the Woolf process by electrolysing sea water or weak brine (2 or 3 per cent. NaCl), and was originally introduced in America. It is a yellowish fluid of chlorous odour, sp. gr. about 1·02, and contains hypochlorites and chlorides, the "available chlorine" from the former being, according to my analysis, about 0·355 per cent., or practically decinormal. It has been extensively used in the States for disinfecting and deodorising sewers, garbage, &c., and the reports of American chemists and bacteriologists are eminently favourable. At Brewsters, N.Y., it has been used for some years to purify a bad water, a portion of the New York City supply. E. W. Martin, Chemist to the Health Department, N.Y., states that 1 part to 100,000 of water "largely oxidised the nitrogenous organic matter, converting the greater part of the free and albuminoid ammonia, and all the nitrites, into nitrates. It also killed most, and, in some cases, all the bacteria."

A series of trials were conducted in 1898 by Professors Robinson, Kanthack, and the author as to the treatment with "electrozone" of the sewage effluent at Maidenhead. One part of the fluid was added to from 400 to 800 parts of effluent, the amount being regulated so that after the mixture had run through an open channel for two minutes, the liquid at the outfall still gave a blue colour with potassium iodide and starch. The chemical and bacteriological analyses agreed in showing that electrozone used as above has no appreciable effect on the organic matter in sewage, but that it has a marked germicidal action, and that if the organic matter be previously reduced by filtration, or by a bacterial process to a low limit, electrozone will produce an effluent nearly colourless, free from odour, and containing very few bacteria. "Meditrina" is a slightly stronger form of the above, prepared for medical and surgical use.

The reason for the small action on the organic matter was elucidated in the author's report. The sewage was found to require for complete oxidation about 11 parts of O per 100,000, whilst the amount of "available Cl" added was only about 0·55 parts per 100,000. As 35·5 parts of Cl have an oxidising efficiency equivalent to 8 parts of O, it will be seen that the amount of fluid added must be increased nearly one hundredfold to effect complete oxidation. This only supports what I have emphasised before, that although many disinfectants, *if used in sufficient quantity*, can kill bacteria and destroy offensive matter, the amount required is far in excess of what is prescribed, and becomes almost prohibitive as to cost. Chlorine and hypochlorites, and, indeed, other chemical disinfectants, practically fail when applied to the solid matters of sewage. Although the chlorine, when brought in contact with the germ, is capable of killing it, it only does so because it oxidises the organic matter in the germ; but, on the other hand, in presence of a large amount of organic matter the chlorine often expends itself on the latter before it has time to sterilise the organisms.

Inasmuch as all hypochlorite solutions are alkaline, and it is known that the growth of bacteria is encouraged by weak alkalies, and hindered by acids, it has been proposed to acidify these solutions so as to evolve chlorine or hypochlorous acid. Outenin-Chalandre (Eng. pat. 15,834, 1896) during the electrolysis of salt solution adds hydrochloric acid continuously. While, however, alkaline solutions tend to dissolve albuminoid matters, and therefore penetrate them better, free chlorine and HClO precipitate them, thereby being removed as an insoluble combination which crusts over the

* An example of this has just occurred. The Sanitary Inspector of Glossop reported that "he had tried chloride of lime, in accordance with recommendations, but had received scores of objections to it; in fact, it was a disinfectant which no one would use."—*Chemist and Druggist*, April 30th, 1898.

† *Journal* Soc. Chem. Ind., 1895, page 224.

larger particles, and may protect the interior.* "Chloros" is a solution of sodium hypochlorite, containing 10 per cent. of available chlorine. It is directed to be diluted with 100 volumes of water, which is about 0·1 per cent. available Cl.

Some recent investigations on the quantity of "available chlorine" required to produce an effect on organisms may be quoted. It must be repeated that organisms differ greatly in their resistant powers, a large number disappearing rapidly and with weak solutions, while spore-bearing forms like B. anthracis are most persistent, and that time, temperature, acidity, or alkalinity, light, nature of the matters in solution, and vigour of the culture used, play a most important part in the results, the interference of these factors accounting for the varying results sometimes recorded. A "reduction of the number of organisms" is often easily attained, whereas "absolute sterility" may involve perhaps a thousand times as much reagent, and an equivalent increase in the cost. In the following examples "Cl" means available chlorine, *i.e.*, that which is either free or belongs to the hypochlorites. "Parts" means parts per 100,000.

Kanthack in 1898 found that 0·3 to ·36 parts of Cl reduced the organisms in sewage effluents from innumerable to 10—50 per cubic centimentre.

In a laboratory experiment in the same year the author observed that when sewage was treated with 1·77 parts of Cl, although from 44 to 66 per cent. of this immediately combined with the organic matter, plate cultivations taken after 14 minutes' contact showed no growth at room temperature in three and a-half days.

Professor Delépine, of Owens College, finds that a 1 in 50 solution of chloride of lime (=0·661 per cent. Cl) disinfects tuberculous matter, while 1 in 10 (=3·3 per cent. Cl) kills anthrax spores in a very short time, and that the latter solution will keep in the dark for over twelve months. A liquid of 1 in 50, or even 1 in 100 strength, is syringed over the walls, and the room closed till the next day. Drs. Sims Woodhead and Cartwright Wood have repeated and confirmed Delépine's results, which may also be illustrated by the earlier work of Nissen and Bolton. The former found as the effective times and strengths: †

Organisms.	Time in minutes.	Bleaching powder, per cent.	Available chlorine, per cent.
Typhoid and cholera	5	0·12	0·04
Anthrax *bacillus*	1	0·10	0·033
Staphyl. pyogenes aureus	30	0·2	0·066
Anthrax *spores*	30	5·0	1·67
" "	70	1·0	0·33

Bolton states that 1 in 2000 of chloride of lime (=0·017 per cent. available Cl) destroyed typhoid and cholera germs in two hours, while anthrax spores required a 1 per cent. solution (0·33 per cent. Cl).

Dr. Porter has carried out disinfection by 1 per cent. chloride of lime at Stockport for the last three years.

Prof. Boyce states that 3 per cent. of sodium hypochlorite solution (= 0·3 per cent. of available Cl) killed B. coli, typhosus, and Sp. choleræ in broth cultivations in two hours, but not B. anthracis when spore-bearing. One per cent. (0·1 per cent. Cl) in two hours killed all except B. subtilis and anthracis.*

Dr. G. C. Clayton further found that anthrax spores required 2·5 per cent. Cl acting for thirty minutes, adding that 5 per cent. Cl acted in one minute, 0·5 per cent. mercuric chloride in the same time, while phenol failed to sterilise.†

In Dr. Klein's experiments,‡ sodium hypochlorite was diluted with definite volumes of sterile distilled water, and separate tubes inoculated with nine species of organisms including some anaërobic and spore-bearing forms. After definite times, sub-cultures were made, and incubated at 37 deg. Cent. for four days, (B. enteriditis at 20·5 deg. Cent. for six days). "By this time any living microbes would have had ample time and opportunity of producing easily visible growth." The non-sporing microbes were killed by 1 in 200 solution (= 0·05 per cent. Cl) in five minutes, while weaker solutions required an exposure so long as to be impracticable. Anthrax and enteriditis were killed by 0·1 per cent. Cl in 1½ hours. In sewage 1 of hypochlorite in 100 of fluid destroyed all non-sporing microbes in ten minutes, B. mesentericus apparently in thirty minutes.

THE MANCHESTER REPORT ON SYSTEMS OF SEWAGE PURIFICATION.

(Continued from page 564.)

CHORLEY SEWAGE WORKS.

THE deputation visited these sewage works on January 10th, 1898. They were met by the Mayor, the Town Clerk, the Borough Surveyor, and several members of the Chorley Corporation.

The town contains 5964 houses, and has an estimated population of 26,000. Upwards of four-fifths of the houses are at present drained on the conservancy system; the remainder, amounting to about 1190 houses, with a population of 5355, is supplied with water-closets. The sewers are constructed to take a portion of the rainfall as well as the sewage, and a stream is intercepted by the sewers. Overflows are provided, which come into use in times of storm.

The City Surveyor is informed that from 600,000 to 1,000,000 gallons of sewage reach the works daily in dry weather. The works are about one mile from the town, and are situated on six acres of land which was formerly used as a sewage farm. The system adopted is that of chemical precipitation, followed by downward continuous flow filtration. There are eight precipitation tanks, 90ft. by 47ft. 6in. by 6ft. 9in. in depth. The sewage is chiefly domestic, and contains no chemical or other manufacturing refuse. It is treated with ferrozone in the proportion of about 10 grains per gallon.

There are fifteen filters, 55ft. 6in. by 15ft. by 3ft. 3in. in depth. Twelve of these are composed of sand, gravel, and polarite. Two were formerly filled with sand, and one with sand and coke breeze. The material in the latter three filters has

* *Journal* Soc. Chem. Ind., May 30th, 1896.

† *Ibid.*

‡ *Lancet*, Nov. 28th, 1896.

been removed, and these filters have been recently filled with sand and magnetite. The treatment of the sewage is carried on during the day only, at night it is run into settling tanks.

The deputation were informed that the Corporation had difficulties in dealing with the waste water from the sand washing. Two men were employed in washing the filter sand, and the dirty water resulting from this work formally discharged into the effluent stream on its way to the river. The Ribble Watershed Committee used to take samples below the point where the water from the sand washing entered the effluent channel, with unfavourable results, and consequently the Town Council have recently constructed two large intercepting tanks for the storage of the foul water which results from the washings of the filters. This water is run back to a well, and from thence it is pumped into the precipitation tanks for re-treatment.

The cost of the buildings and works, exclusive of the new intercepting tanks and of the site, was £16,750. The new intercepting tanks cost £650, making a total of £17,400. Samples of the sewage and effluent were obtained by the Committee's chemist, and the following is his report:—

Description of Samples.—Two samples of sewage were taken, the second sample being darker and greyer in appearance than the first, which was more brown. Sample No. 1 was taken at 2.45 p.m.; sample No. 2 at 3.15 p.m. The tank effluent was bright and clear at first, but deposited a slight flocculent precipitate on standing: it was taken about 2.50 p.m. The sand filter washings contained, besides the washed-out sand, a considerable amount of brown suspended matter. They were sampled about 3.10 p.m. The filtered effluent was bright and clear, and remained so; it was taken about 3 p.m.

Analytical Numbers.

	Grains per gallon.			
	Oxygen absorbed, 4 hours.	Free and saline ammonia.	Albuminoid ammonia.	Chlorine
Sewage No. 1 (shaken) ...	5·68	1·57	·945	5·0
,, ,, (settled) ...	2·54	—	·35	—
,, No. 2 (shaken) ...	7·24	1·92	·805	5·0
,, ,, (settled) ...	3·74	1·82	·49	—
Tank effluent	·48	·425	·20	2·9
Filtered effluent	·13	·01	·035	3·5
Sand washings	1·94	·42	·74	—

Incubator Tests.

	Grains per gallon. Three minutes' oxygen absorption.		
	Before incubation.	After incubation.	Putrescibility.
Sewage No. 1 (settled)	·88	3·30	Very foul.
,, No. 2 ,,	1·44	4·12	Very foul.
Tank effluent	·16	·11	Putrescent smell.
Filtered effluent... ...	·06	?	No smell.
Sand washings	·70	·84	Smell badly.

The quantity of filtered effluent was too small to allow of an accurate determination of the three minutes' oxygen absorption after incubation. It remained, however, perfectly sweet. Though the tank effluent smelt unpleasantly on removing from the incubator, the amount of putrescence is very small compared with the settled sewage. The chlorine numbers, however, show that the tank effluent probably corresponds with a weaker sewage.

Samples were taken from the top and bottom of a long carrier, down which the filtered effluent was allowed to flow in a thin stream, in order to see whether any appreciable oxidation would be effected by the air. The numbers were as follows:—

	Grains per gallon.			
	Oxygen absorbed, 4 hours.	Free and saline ammonia.	Albuminoid ammonia.	Chlorine.
Top of fall... ...	·19	·027	·032	2·8
Bottom of fall ...	·13	·045	·027	3·2

There is evidence of a small improvement, some of the albuminoid being converted into free ammonia, but the change is not striking. A mixture of filtered effluent from the top and bottom of the fall was found to contain nitrogen as nitrates to the extent of ·40 grains per gallon.

Chemical Report.—This sewage is of a domestic character. The precipitant used, called ferrozone, is a crude sulphate of alumina, containing some sulphate of iron. Ten grains of this are added per gallon of sewage, being equal to about 15 cwt. per million gallons, which at the present price of ferrozone would cost about four times as much as the quantity of sulphate of iron used at Davyhulme. No lime is added at Chorley. The tanks are worked on the quiescent principle, allowing three hours' settlement as a minimum; whereas the tanks at Davyhulme are arranged on the continuous-flow system. Great attention is paid at these works to the washing of their filters, each filter being washed once a week by the upward flow of the effluent from two other tanks. The filters are given ample periods of rest, and it is stated that the whole series is capable of passing 1½ million gallons per day, giving a good effluent. The quantity at present passed over the filters is 1,000,000 gallons per twenty-four hours through 1500 square yards, which equals 666 gallons per square yard per twenty-four hours, or about 3,000,000 gallons per acre. Taking the flow of sewage at Manchester at 26,000,000 gallons per twenty-four hours, about nine acres worked at the same rate would be required for filtering the Manchester sewage effluent. The filtered effluent is of a good character. The chemical precipitation alone shows a large amount of purification, although the tank effluent is putrescent. The filters remove all liabilities of this kind. There is evidence in the filtered effluent of an improvement, through the subsequent aëration as it flows to the stream. The washing of the filters and the liquid coming from such washing seem to offer some difficulty in the method of purification.

Report as to Cost and General Working of Filters.—The result produced here by the filters is satisfactory, but their adoption in Manchester would involve a very large capital outlay, and also very heavy working expenses.

OLDHAM SEWAGE WORKS.

The deputation visited these works on Wednesday, January 12th, 1898. They were met by Mr. H. Law, M. Inst. C.E., the Engineer of the Works, and were afterwards joined by the Mayor and other

members of the Corporation and the Borough Surveyor.

Mr. Law kindly described the works, and subsequently supplied particulars of working and the appended plan.

The method of treating the sewage of Oldham at the sewage disposal works at Slack's Valley is as follows :—The sewage having passed through a screening chamber, in which the coarser solid matters are removed, receives first a dose of 3·7 grains of lime and afterwards one grain of protosulphate of iron for every gallon, and then passes a paddle-wheel by which a perfect mixture of the chemicals with the sewage is insured. Both the lime and the protosulphate are presented to the sewage in a perfect state of solution, and are automatically poured into it in the required proportion.

For the preparation of the saturated solution of lime, the lime is reduced to the state of cream of lime in one of Michele's lime mixers ; a regulated quantity of the cream of lime is admitted to the suction pipe of a centrifugal pump, by means of which one-twentieth of the sewage effluent is raised into a tank capable of containing 300,000 gallons. There are two tanks, so that one is settling while the other is supplying the clear saturated solution of lime to the sewage.

In the mixing room is a well communicating with the sewer, and containing a float, which rises and falls according to the greater or less flow of sewage, and by its movement regulates the height of a weir, over which the lime water falls into the sewer. In a similar manner a saturated solution of the protosulphate of iron is obtained by keeping a cage filled with the protosulphate immersed in a tank of water, from which it passes into the sewer through a hole partially closed by a conical plug, the height of which is dependent upon that of the float in the sewage well, and thus regulates the quantity of the solution of protosulphate mixed with the sewage.

Mr. Law is of opinion that by the ordinary method of mixing the sewage with cream of lime, it is quite impossible to determine the actual quantity of lime so used, which may be half or twice as much as intended, depending upon the varying consistency of the cream of lime. Furthermore, when the lime is supplied to the sewage in a state of perfect solution a perfect and intimate mixture takes place, every particle of the sewage coming into contact with the lime. The above referred-to float is connected with a self-recording gauge, by which the actual flow of the sewage is automatically and continuously recorded.

After the chemical treatment the sewage passes on to the precipitating tanks, of which there are twelve, each 125ft. long, 36ft. wide, and 6⅛ft. in depth, and containing 172,260 gallons. These tanks are worked on the continuous principle ; the sewage entering, and the effluent leaving, the tank over weirs the full width of the tank. One of these tanks was converted into an experimental filter, composed of a layer of 9in. of stones, about an inch in diameter at the bottom, and above that 4ft. of ashes—that is to say, cinders or clinkers from the mill furnaces, the larger lumps being broken into pieces not exceeding 1in. to 1½in., and the dust being separated by screening.

The effluent from the tanks is run on the filter until it just appears upon the surface ; it is then left for an hour in the filter, and the filtrate is then gradually drawn off, and an hour's perfect rest is allowed before again filling the filter ; and the filter is allowed one day's entire rest once every week. The results thus obtained were so satisfactory that it was decided to adopt the system for the treatment of the whole of the sewage, and about three acres of filters are being constructed.

The sides of these filters are lined with timber camp shedding, the filtrate is withdrawn through drains formed with agricultural drain pipes, and the effluent is conveyed on to the filter in wooden troughs. The depth of filtering material is 28in., and the results obtained are said to be perfectly satisfactory. The cost of these filters is about £700 per acre, which includes the cost of excavation and of puddling the weak parts of the ground. The crushed clinkers of which the filters are composed cost just under 2s. 6d. per cubic yard *in situ*. The above cost is exclusive of main carriers or roadways. These filters are filled and emptied twice in twenty-four hours.

(To be continued.)

THE PURIFICATION OF THE SEINE.

In a paper contributed to the *Bulletin de la Société d'Encouragemeut* M. G. Bechmann, the Chief Engineer of the Sanitary Department of Paris, gives a very full account of the methods and work which have been employed for the protection of the Seine from sewage contamination, and the measures which have been taken to develope the sewage farm system in the vicinity.

The supply of drinking water for Paris is brought from a distance, and the discharge of sewage into the Seine had no bearing upon that problem, but the foul condition of the river long ago called attention to the necessity of doing something, and in 1855, when the transformation of Paris under the energetic direction of Haüssmann was undertaken, measures were taken to prevent the discharge of sewage into the river within the limits of Paris.

This was accomplished by carrying large collecting sewers along each bank of the river to receive the discharges from the sewers which had formerly emptied directly into the stream, these collectors delivering the entire discharge into the Seine at Asnieres, below Paris, the bend of the river making this connection direct and convenient.

So far as the residents of Paris were concerned, this work, which was completed in 1867, was entirely satisfactory, but the increasing foulness of the river below Paris soon called for relief, and, after the troubles of 1870—71 were over, the sewage farms of Gennevilliers were started, and what was formerly a sandy waste was converted into a thriving market garden, while the river was also much improved.

Since then urgent efforts have made to extend the system, mainly through the efforts of the engineers of Paris, MM. Mille and Durand-Claye, but for a long time there was a most unreasoning opposition among the residents and property-holders of the department of Seine-et-Oise, who feared that their property was to be depreciated by the creation of an offensive nuisance. Prohibitory damages were demanded, and even the Local Authorities united with mobs to interfere with preliminary surveys ; hence it took from 1875

to 1889 to secure the passage of the necessary legislation for the construction of the great sewage works and farms at Achères, now completed.

Owing to the several bends in the Seine, the sewage canal by which the discharge is conducted to Achères crosses the river three times. At Clichy pumping is resorted to, four large centrifugal pumps, with vertical axes, each pump directly connecting to its own Corliss engine, lifting the sewage in order to give sufficient head to enable it to pass through a tunnel under the river. The pumping station is arranged to permit the installation of four additional pumps, which will ultimately provide ample capacity for double the existing requirements. The tunnel is itself an interesting piece of work, having been pierced through the bed of the Seine by means of the Greathead shield system, using compressed air and hydraulic pressure, the finished tunnel being lined with bolted cast iron sections.

The second crossing of the Seine at Argenteuil is by means of a handsome steel arch aqueduct bridge, a second pumping station at Colombes lifting the flow to the required height, from which the principal aqueduct at Achères conducts and distributes the sewage over the farm territory. A portion of the land at Herblay lying in another bend of the river required a third crossing, which was accomplished by a submerged syphon composed of two riveted steel pipes. This syphon was prepared upon the surface and then sunk to a foundation of piling at the river bed, the pipes being bedded and enclosed in concrete.

The completion of this great work practically takes all Paris sewage-discharge from the river and deposits it in a dilute and inoffensive form upon a sandy, gravelly tract, formerly worthless for agricultural purposes, and now rapidly becoming valuable garden land. The water, after it has filtered through the soil, is practically clean and pure, and there is not the slightest objection to its discharge into the river, where it finds its way only by the slow natural process of percolation through the porous soil.

The engineering details of this great work reflect much credit upon M. Bechmann and his assistant, M. Launay, for, although the general plans were executed practically as they had been conceived and arranged by MM. Mille and Durand-Claye, many important constructive features had to be devised as the work progressed. The entire operation of the system is even yet not complete, but it is expected that those who visit the Exposition of 1900 will find the Seine as free from contamination as if Paris were not situated upon its banks.

LONDON.—At the last meeting of the County Council a report was presented by the Public Control Committee stating that a circular had been issued to Local Authorities, calling attention to the seriousness of the smoke nuisance in various parts of the metropolis. Sir H. Poland remarked that a serious danger arose in the waterside parishes from the smoke emitted by the river steamboats. He moved that Committee take into consideration the propriety of making representations upon this matter also. He pointed out that to plead that smokeless coal was unobtainable was no answer to a prosecution under the Abatement Act. The Council agreed to the suggestion.

MILK ANALYSIS.

AT a recent meeting of the Nottingham section of the Society of Chemical Industry, held at the Nottingham University College, a paper was read by Mr. Samuel Trotman, the Nottingham Borough Analyst, on the subject of "Milk Analysis." In the course of his introductory remarks Mr. Trotman said that although the work of an analyst did not often lead to important scientific results, still it frequently happened that the accumulation of small facts provided matter of general interest, and acting in accordance with this belief it was his intention to lay before the meeting a few statistics in reference to the milk supply of the city of Nottingham. These, if not particularly striking from a scientific point of view, needed no apology when regarded from the standpoint of public health and economy. There were few natural foods more necessary than milk, and yet, strangely enough, there was none so readily taken without proper inquiry into its source of origin and conditions of production.

After alluding to the general belief that the constituents of milk were subject to considerable variation, whereas they were, in point of fact, remarkably constant and uniform, the lecturer gave some statistics in support of his contention. During 1895, for instance, Mr. H. D. Richmond, of the Aylesbury Dairy Company, had analysed some 24,662 samples, with the average result of a percentage of 3·84 of fatty substance, and 8·82 solids, not fat, while in no case did the percentage of fats fall below 3 per cent. Similar analyses of large numbers of samples in succeeding years gave almost identical results. From this it might reasonably be concluded that, without inflicting any hardship upon the producer, one might expect to find the milk supplied for the daily use of the public not much below the standard quoted. In Nottingham, however, this standard was far from being attained.

During the past eighteen months the speaker had examined 180 samples of milk, with the following average result :—Fat, 3 per cent.; solids not fat, 8·5 per cent. Of these samples only 35, or 19 per cent., reached the average of the samples analysed by Mr. Richmond. In nearly every case, too, the samples were mixed, and not the produce of any individual cow, so that the conditions were identical in both cases. Of the remaining 145 (adopted as a standard of purity 3 per cent. of fat and 8·5 per cent. solids not fat), 62 were deficient in fat and 73 contained added water, representing altogether 96 undoubtedly adulterated samples. This was noteworthy in view of the fact that, according to Mr. Richmond, it was exceedingly rare to find a genuine milk in which the fat fell below 3 per cent., while the same gentleman gave it as his opinion that the solids not fat below 8·5 were only 2·18 per cent. of the samples he analysed. The difficulty analysts had to contend with was the absence of a legal definition of the composition of milk. The facts he had adduced proved that it would not be difficult at the present time to fix a standard which would protect the consumer without inflicting any hardship or injustice upon the producer.

In answer to the objection that individual cows sometimes gave very poor milk, he maintained that such a state of things was invariably due either to

bad feeding or to debility in the animal. If the former were the case, the remedy was obvious; if the latter, the cow should be condemned for milking purposes. Of the 180 samples he had analysed, and which had been offered for sale in Nottingham, no less than 62 were deficient in fat to the extent of at least 32 per cent., while 73 contained added water; yet in very few cases were the Authorities able to prosecute with the certainty of obtaining a conviction. As things stood at present, even in cases where there was the straightest evidence of adulteration, the milk had still to be passed as pure. Thirty per cent. of fat might be abstracted from 10 per cent., and often 20 per cent. of water added with impunity.

Passing to another aspect of the question, Mr. Trotman said he had recently examined over fifty samples of Nottingham milk under the microscope, and in almost every case there was a deposit of a blackish colour. This was directly due to the presence of cow dung, and every specimen contained hairs, ranging from minute ones, apparently from the cow's udder, to the long capillary appendages of the dairymaid. Other foreign bodies included fungi and fragments of vegetable *débris*. Bacteriological investigations led to equally significant results. The experience of Nottingham milk, he added, was only on a par with that of other large towns. Evidence of a similar nature to that embodied in his paper was coming in from every side, and yet little or nothing was being done in the way of reform. It was his opinion that in a city of the size of Nottingham the sterilisation and distribution of milk ought to be in the hands of the Public Authorities, who would thus become guarantors to consumers of the quality and sanitary condition of the milk supplied. This was already the case in many towns on the Continent, and would not necessitate the raising of the price of milk, while it would abolish the necessity for the delivery twice per day. The whole question was one which should be regarded rather from the welfare of the many than the feelings of the few.

ROYAL INSTITUTE OF PUBLIC HEALTH.

Forthcoming Congress and Exhibition at Dublin.

The annual Congress of the Royal Institute of Public Health will be held in Dublin from 18th to 23rd August, 1898, at the invitation of the Corporation of Dublin. It will be under the patronage of the Lord Lieutenant, the Honorary Presidency of the Lord Mayor, and the Presidency of Sir Charles A. Cameron, Superintendent Medical Officer of Health. The meetings will be held in Trinity College. The section of Preventive Medicine will be presided over by Dr. Grimshaw, C.B., Registrar General; of Chemistry and Climatology, by Dr. John W. Moore; of Engineering and Building Construction, by Sir Thomas N. Deane; and the Parliamentary and Municipal section by the Right Hon. Joseph M. Meade, P.C., LL.D. Conferences of Army Medical Officers, Veterinarians, Medical Officers of Health, and Sanitary Inspectors will respectively be presided over by Brigade Surgeon Lieut.-Colonel Corbett, D.S.O., Chief Veterinary Inspector; Matthew Hedley, Privy Council; Dr. Thomas J. Stafford, Commissioner Local Government Board; and Mr. Conway Scott, Executive Sanitary Officer, Belfast.

Amongst the subjects fixed for discussion are the "Housing of the Very Poor," "Tuberculosis in Animals used as Food," "Enteric Fever in the Army," "The Examination of Candidates for Sanitary Officers," "Combined Drainage." The Army Medical Staff will give a demonstration of "First Aid to the Wounded" in the College Park. There will be demonstrations in bacteriology, calf vaccination; the best method of heating and lighting, &c. The festivities of the Congress will be worthy of the reputation of Dublin as a hospitable city. The Lord Mayor will give a ball, the High Sheriff a luncheon the Corinthian Club a dramatic and musical entertainment, Sir Henry Cochrane and Sir Christopher Nixon garden parties, and other entertainments will it is expected be also offered by leading citizens. The Hospitalities and Excursions Committtee are arranging for excursions during and after the Congress meeting. The celebrated Dublin Horse Show commences on the closing day of the Congress.

Full information of the Congress can be obtained by applying to the Secretaries, Public Health Office, Dublin. In connection with the Congress a Health Exhibition will be held at the Royal University Buildings, from Thursday, August 18th, to Saturday, August 27th, under the auspices of the Institute. It is expected to be on an elaborate scale, and will extend over horse show week, when Dublin will be thronged with visitors from all parts of the kingdom. No important exhibition of a similar character has been held in the city for fourteen years, during which period sanitary science and practice have made immense progress. "The old ways of sanitation," as the Committee point out in their preliminary circular, "have been improved, or have given place to new methods and appliances which inventors and manufacturers desire to make as widely known as possible." They also point out that in every exhibition of the kind a mutual benefit is conferred between the exhibitors and the public, and they earnestly invite exhibitors to put forward only the best possible modern appliances, so as to render the event exceptionally interesting, educational, and successful.

The Board of Trade will be applied to for protection of all novelties exhibited in accordance with the Patents, Designs, and Trades Marks Acts of 1883, and music and other attractions will be provided for the enjoyment of those who will visit the Exhibition. The Committee promise that no effort will be spared to render this the most important and successful Health Exhibition of recent years. The exhibits will be arranged in twelve sections, under the following heads:—Scientific, including such subjects as Physiology, Bacteriology, and Geology, Public Hygiene, Domestic Hygiene, Water Supply, Sewage Treatment and Disposal, Drainage and Plumbing, Heating, Lighting, and Ventilating; Personal Hygiene, including clothing, dress fashions, food, perfumes, and woollens; Electrical Installations and Appliances, Disinfection, Locomotion, including bicycles, tricycles, and motor cars, and Miscellaneous Exhibits, such as ambulances, life-saving appliances, models, and toys.

EFFICIENT DRAIN TRAPS.

By Dr. HERBERT JONES, Medical Officer of Health, Rhondda Urban District Council.

A TRAP may be described as a double bend in the course of a pipe, enabling water to remain in

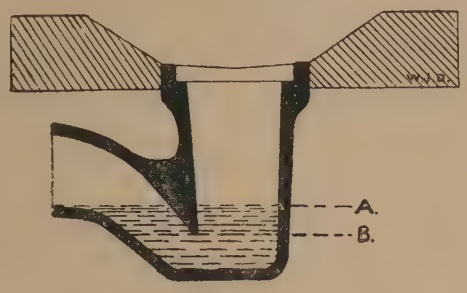

Fig 1.

the pipe in such a position that air cannot under ordinary conditions pass through it.

The bye-laws in force in this district do not prescribe any particular form of trap to be used, they merely require an "efficient" trap. The essentials

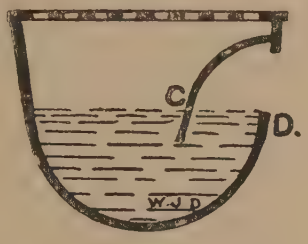

Fig. 2.

of an "efficient" trap are, that it shall be self-cleansing, that it shall have a seal of at least 1½in., and that it shall be fixed in such a manner that the drain cannot be untrapped by removing the trap from its position.

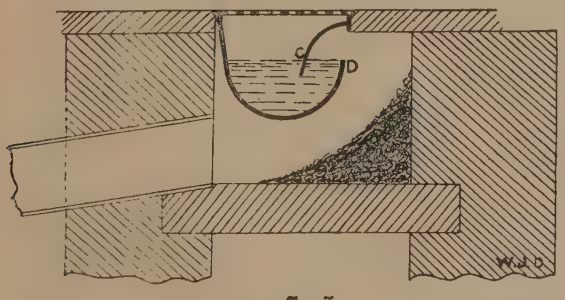

Fig 3.

Fig. 1 shows a trap that very fairly meets these requirements. The "seal" is that portion of the water between A and B. The rounded corners, the material of which the trap is made (earthenware or stoneware), and the flattened bottom, ensuring proper fixing, all add to the self-cleansing properties of this type of trap; though in actual practice it is found desirable to clean it out every week or so.

Fig. 2 shows a form of trap known as the D or lip trap, and the sketch is only given that the trap may be condemned. It has been well described by Sir William Jenner as the double D—"disease and

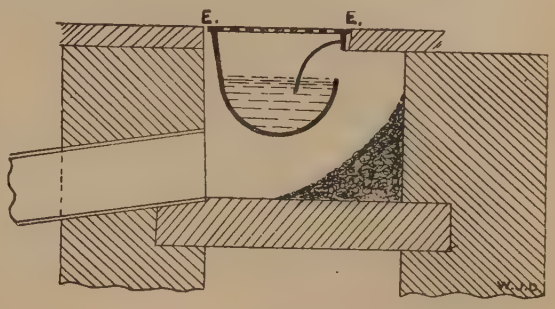

Fig 4.

death dealing"—trap. Being made of iron, the parts C and D very often get chipped off or corroded, whereby the small seal that originally existed is made still smaller, even if it does not altogether disappear. It will be noticed that this so-called trap is not fixed directly on to the first

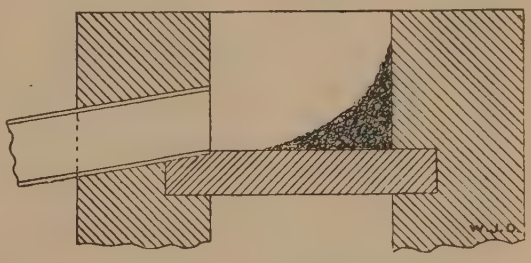

Fig 5.

drain pipe in the same manner as the stoneware gulley, but it is merely placed on the top of a square sump as in Fig. 3, which is lined with bricks more or less imperfectly placed, permitting all kinds of filth to soak into the surrounding ground. But this

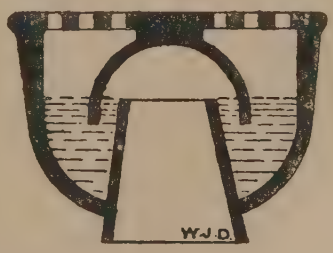

Fig. 6.

is not the worst feature of the D trap (?). Fig. 4 shows the manner in which it is usually placed, all awry, and without any attempt being made to cement it to the stonework or brickwork; for all practical purposes, therefore, there might just as well be no trap at all, for the air from the

sewer can quite easily pass out at the sides of the trap at E E. Again, it is the custom for the householder to take the whole trap away from the drain, as in Fig. 5, in order to pour water down more quickly, indeed where these traps are in use, it is the exception rather than the rule to find one in its proper position, and there is always more or less filthy deposit as shewn in the sketches.

The bell trap shown in Fig. 6 has nearly all the objectionable features of the D trap. It very readily becomes choked, and then the grating is taken off to remove the blockage, when the air from the drain has free access to the external air.

It cannot be too often insisted that a trap is not an all-sufficient safeguard from sewer gas. The water seal may be forced by pressure, or may absorb gases on the drain side and deliver them up on the house side, or the bottom of the trap may be so loaded with filth that the decomposition of this will enable putrefactive gases to force their way through the seal.

THE SMOKE NUISANCE: AN INTOLERABLE STATE OF THINGS.

IT is fortunate for Londoners, remarks the *Lancet*, that the present period of the year happens to be spring, and not winter or late autumn, for the Welsh coal strike appears to have given opportunity to hotel and restaurant proprietors and others to commit a serious breach of hygienic law. The appearance of several of the great thoroughfares of the metropolis has for the last few weeks forcibly suggested the Black Country. Never was London deluged in blacker smoke on all sides than it has been recently. The Strand in particular, that avenue of cafés, restaurants, and hotels, is a disgrace as it is a reproach to the Public Health Authorities concerned. For the last few weeks this thoroughfare has been bathed in murk and gloom, and the atmosphere has been offensive with sulphurous emanations and irritating smuts. The nuisance continues at the time of writing with unabated vigour, and we possess a carefully-kept record of the foul vomiting of several chimneys in the immediate vicinity of the offices of the *Lancet*. It goes on, not for minutes, but for hours, and is not only a nuisance to health, but a source of considerable injury to property.

The effect on buildings decorated with light colouring is disastrous, and the paint everywhere rapidly assumes a deteriorated appearance. All endeavours to keep windows clean are utterly futile. And to open them is only to invite layer upon layer of soot to cover our books, papers, and manuscripts. Even at Westminster they have noticed it, for in answer to a question put by Mr. Labouchere in the House of Commons last week it was stated that the matter was one with which it was the business of the County Council to deal. The plea that the nuisance is caused through the difficulty of getting Welsh or comparatively smokeless coal is idle. The smokiest coal can be burnt without evolving dense or almost solid smoke by the adaptation of a suitable and simple smoke-consuming contrivance above the furnace. It is certain that if the meteorological conditions of winter had prevailed, the smoke would have been locked in by particles of moisture and the worst possible kind of fog would have hung over the metropolis. It is the duty of the London County Council to set in motion the powers vested in them under the Public Health Act, containing as it does a clause which runs as follows: "Any chimney (not being the chimney of a private dwelling-house) sending forth black smoke *in such quantity* [the italics are ours] as to be a nuisance shall be deemed to be a nuisance liable to be dealt with summarily in a manner provided by this Act." Then why are the offenders not "dealt with summarily"?

[We commend to the notice of all who are interested in the important question of smoke prevention, the valuable booklet just published by the Sanitary Publishing Company, Ltd., entitled "Practical Smoke Prevention," written by Mr. W. Nicholson, Smoke Inspector, Sheffield.—ED.]

PROGRESS OF DISINFECTION IN PARIS.

THE Parisian Bureau of Disinfection has made an important report to the Municpal Council upon the results accomplished under the modernised methods employed for the restriction of infectious disease. From this report it appears that in seven years, with a staff which numbers eighty people, the organisation has carried out in Paris more than 171,000 disinfections, the annual average being at present nearly 40,000. In 1886, before the service was organised, there died in Paris nearly 6000 persons, carried off by epidemic diseases. Ten years afterwards, in 1896, the number, which had been gradually falling, fell to below 2000; that is to say, that 3000 or 4000 human lives were saved every year. Without doubt the works which have been carried out of bringing water straight from the springs have contributed greatly to the amelioration of the sanitary condition of Paris, but disinfection has also played a large part.

The total mortality, which was 54,536 in 1892, the date at which the disinfecting service was first organised, fell in 1897 to 46,987, that is to say, an average of 18·54 per 1000 inhabitants in place of 22·47. The principal part of this very considerable diminution in the mortality of Paris is accounted for chiefly by the diminution in zymotic diseases. The mortality from these diseases, which was formerly one-tenth of the whole, fell gradually to one-eighteenth between 1891 and 1895, one-twenty-sixth in 1896, and one-twenty-seventh in 1897. Enteric fever in 1892 accounted for 691 deaths and in 1897 for 231. In 1892 there were 42 deaths from small-pox, and only 12 in 1897. In 1892 there were 909 cases of measles, and only 811 in 1897. The deaths from scarlet fever, which were 158 in 1892, fell to 76 in 1897. There were 334 cases of whooping-cough in 1892, and only 282 in 1897.

Finally, diphtheria, which gave rise to 1403 deaths in 1892, was the cause of only 306 in 1897. M. Landrin observed that tuberculosis remained stationary because prophylaxis against this terrible disease, which is accountable for one-quarter of the whole mortality, is not yet a definite part of the social system. He reminded his audience that both the Municipal Council and the Government are ready to make a great effort to fight against tuberculosis. In addition to the measures taken in hospitals, and the system of treating the poor at their homes, as well as those unfortunates who are under the care of the Assistance Publique, measures

were taken during 1897 by the municipal disinfection organisation with the view of carrying out a more complete and methodical campaign against tuberculosis. The report concludes with the recommendation that measles, which is to-day one of the most fatal zymotics, should be made a compulsorily notifiable disease.

INOPERATIVE SANITARY LEGISLATION.

ON Tuesday week a conference, convened by Canon Barnett, the warden, was held at Toynbee Hall, Whitechapel, for the purpose of considering the inoperativeness of various sanitary laws. Sir Arthur Arnold, London County Council, occupied the chair, and there was a good attendance, many local sanitary officials from the East End districts being present. The discussion was opened by the CHAIRMAN, who complained of the insanitary condition of many rural districts. With some of these the slums of the East End would bear no comparison. He believed that if the benefits arising from cleanliness could be demonstrated to the masses their condition would improve rapidly.

Dr. SCHOFIELD then read an interesting paper, in the course of which he contended that London owed its singularly low death-rate to operative health laws, and rural districts were at least fifty years behind the metropolis in regard to sanitation. Having referred to the filthy condition of Oriental cities and its consequences, Dr. Schofield expressed the firm opinion that health laws were operative in this country to a greater extent than in any other country in Europe or Asia. But still much required to be done, for there were three barriers which could be raised against death, viz., the public, the professional, and the private barrier. It was to the last of these three that he had devoted so many years of his life, and had been trying to teach the women of England how important it was that they should be cleanly in their work and habits. He had given more attention to the cleanliness among women because the health of the population depended so largely upon them. Miss Florence Nightingale had made the startling statement in "Village Life in England" that the average woman seldom washed, and he had inaugurated an organisation of nurses to visit the cottage homes of England to point out the sanitary defects of their dwellings and the benefits of personal cleanliness. Sanitary officers said it was impossible to carry out sanitation and sanitary laws in the country as was done in London, but he believed that the laws would have to be gradually carried out until their observance became general. When it was considered how the people were crowded together in London, on a flat, marshy soil, with drinking water, one half of which was used for sewerage purposes, the sanitary arrangements of London were marvellous. At the same time they were not perfect, and to bring about an ideal state of things they had to consider the causes which made sanitary laws inoperative. One cause was ignorance, for the sanitary laws were too new to be thoroughly understood even by Sanitary Inspectors or magistrates. Apathy and indifference were other causes, and the immense difficulty of enforcing the sanitary Acts was another cause of their inoperativeness. Overcrowding, despite the efforts of the Sanitary Inspectors, was still practised to a great extent, but fines and imprisonment would not stop this evil, because working men could not afford sufficient accommodation. Ignorance on the part of Vestrymen also accounted for a great deal of the delay in dealing with bad conditions. Although there had of late been an improvement, bad Sanitary Inspectors were still to be found. Obstruction on the part of the landlord was also responsible for ineffectiveness of the sanitary laws passed by Parliament. Discussing the remedies, Dr. Schofield suggested that the standard of efficiency of Sanitary Inspectors should be raised, and to increase the knowledge of the health laws among the people.

In the course of the discussion which followed, most of the speeches turned upon overcrowding in East London, and severe criticism was passed upon Mr. Woonton, the Chief Sanitary Inspector of St. George's-in-the-East, who in an interview published in the *East London Observer* had stated there was no overcrowding among the foreign population of his district. Votes of thanks to Dr. Schofield and the chairman concluded the proceedings.

THE VALUE OF A DIPLOMA IN PUBLIC HEALTH.

NOT a few of those many medical men who within recent years have obtained diplomas in public health from one or another of the qualifying bodies will fail, we much fear, says the *Lancet*, to reap a due pecuniary reward for all their labours. We use the term pecuniary reward advisedly, since nothing can take from the possessors of these diplomas the enhanced interest in matters sanitary and social which the knowledge they have thus acquired confers upon them. The disappointment to which reference is made will arise in the main from paucity of appointments and from poverty of pay; but in spite of this it will come as a surprise to many to hear that in some appointments the possessors of experience and of diplomas will be sent away while the owners of neither will be elected. Such, however, has recently been the case in Essex, when, on the creation of a new urban sanitary district out of part of a rural sanitary district, the necessity to appoint a Medical Officer of Health arose. Here there were, we are informed, three applicants: one, the holder of an M.D. degree, who was the Medical Officer of Health of the rural district out of which the new district has been created, and whose name is well known among East Anglian sanitarians; another, besides being a graduate in medicine and surgery, held two diplomas in public health. The third, the selected candidate, was, it appears, untutored either in the school of experience or of special diplomas, and held but the Licentiate of the Society of Apothecaries. What can we say as to this newly-created urban sanitary body but that it, too, presumably possesses neither experience nor diploma? We are afraid that this view of the situation does not excuse the action of its members, because the want of experience from which they suffer should surely have induced them to obtain an experienced officer to guide their faltering footsteps. Fortunately, the Local Government Act of 1888 has done much to prevent abuses of the kind to which reference is here made and renders it very improbable that a

district with a population of some 50,000 will be saddled with a Medical Officer of Health who has had no special training for the post.

COMBINED *v.* SEPARATE SYSTEMS OF SEWERAGE.

THE problem of sewerage and drainage is one which sooner or later every community in the present age of growth and development will have to grapple with. While the water supply is derived from wells, rain-water cisterns, and streams, there is not the demand for any elaborate system of sewerage, because of the ready facilities for disposal of waste matters in cesspools, privy vaults, street gutters, and watercourses. As soon, however, as a regular and abundant water supply is secured, it becomes a matter of necessity to provide proper facilities for the removal of house wastes, which naturally increase in volume with the increased water supply. That is the problem which is made the subject of a recent communication, in which as much light as possible is asked as to the comparative advantages of the combined and separate systems of sewerage, the size of pipes, &c., and a variety of questions an intelligent answer to which calls for a considerable amount of information on a subject not yet satisfactorily settled. We give a few general pointers on the subject, however, which may be of more or less utility to inquiring readers.

The advocates of the combined system of sewerage have at least one very strong argument to use in its favour; it has age to recommend it, dating back from the days of the Romans. But it is claimed that in the light of modern experience it is far from desirable to have a sewer constructed so much in excess of what is ordinarily needed as to provide for contingencies in the way of sudden severe rainstorms which may occur only at distant intervals. The old-fashioned notion of having at all times a sewer or tunnel of brick, 4ft. or 5ft. in diameter, is fast giving way to views based on sound reasoning that it is not at all desirable to construct, at greatly increased expense, a system of sewers which may never, even under the most unprecedented circumstances, be filled to their utmost capacity. It is also claimed that the size of sewers on the combined system presents inducements for disposing of every sort of otherwise indisposable rubbish which could not be put in a smaller sewer—and the further drawback that it is an impossibility, except at rare intervals, to properly flush a large sewer.

The advocates of the separate system maintain that it is essentially necessary to the health of a community that the means of removal of house wastes should be entirely independent of the conduits provided for carrying off storm water, and that such channels should be of such size only as would preclude the possibility of the sewage being stored, as it were, therein in dry weather, without the necessary volume of water to carry it away. But there is more care involved in the proper laying of the pipes, and in the selection of the size and material than may appear at first sight. As regards the material, good salt-glazed earthen pipe should be used, and in the selection of size a governing condition, might be the bore of the water main, because it is tolerably fair to presume that if a given diameter of pipe supplies all the water needed, the same diameter should be sufficient to carry off all of the water which is used in the ordinary purposes of life. It does not happen that all the water supplied is invariably used up as fast as received. On certain days of the week perhaps it does, but it is a fair enough guide to know that if a 5in. main supplies all the water needed, a 5in. sewer should be sufficient for the necessary drainage.

Two other matters should not be lost sight of, viz., automatic flushing and ventilation, both of which are absolutely necessary. At the head or highest level of the main and each of the branch sewers, there should be set an automatic flush tank capable of discharging every six hours or thereabouts a sufficient volume of water to fully fill the bore of the sewer for a distance of about 3ft. or 4ft., so as to completely cleanse and remove everything in it. This column of water in its passage will naturally displace the air in the pipe and drive it before it until some means of escape offers itself, and the method of escape (or ventilation) will require some care and judgment. The commonly-accepted method is the perforated manhole in the street, while those who are opposed to the trap on the main house drain inside the front wall of building consider that if the trap were removed the soil and waste-pipe system would be an excellent medium for ventilating the sewers, as by the ever-changing currents throughout the pipes there would be no opportunity for the generation of dangerous gases. All this, however, presupposes a perfect system of house plumbing, a thing not always general in these days, and the consequence would be, it is claimed, that there would be no protection in the event of contagious disease breaking out in any particular house where sewer communication would have been established.

It is not supposed that this expression of view has in any way disposed of the question as to which of the two systems of sewerage is the more desirable. This is a point which would involve considerably more detail than the writer has time or opportunity to devote to it. Besides, it is a question which has yet to be decided by the sanitarians of the country, and we do not propose to anticipate their action. The separate system, however, seems to us to have the advantage over the combined, in so far that the smaller sewer pipe used is less liable to the generation of foul gases, because of its being more thoroughly cleansed—and there being less liability to obstruction, there is not the same danger to be apprehended from stagnant matter remaining in the pipe. There is also the item of expenditure in construction, which is in favour of the separate system, the outlay being brought down to the minimum of requirements. The combined system means an expense greater than is at all needed in constructing sewers needlessly large to provide for contingencies which may never occur, while the separate system involves nothing beyond the construction of sewers sufficient to carry to a safe distance the house water and sewage of the community.

SANITARY WATER ANALYSES.*

By FLOYD DAVIS.

THE impurities that affect the quality of water for domestic purposes are inorganic and decomposing vegetable and animal matter, and the micro-organisms of disease. Some of these exist in harmful quantities in the water of many streams, and in other sources that flow through or originate in rich agricultural or swampy land and densely-populated districts. A small amount of fine, non-silicious mud or silt in drinking water is not known to produce disease, and is objectionable only from an æsthetic standpoint. But the large amount of angular particles of sand and decaying vegetation found in some streams is frequently productive of intestinal disturbances, like inflammation of the bowels, diarrhœa, and dysentery; and any water that is distinctly turbid should be regarded as non-potable, until it has been clarified and freed of its organic matter.

At certain seasons some algæ produce a disagreeable taste and odour that make it unpleasant to drink water containing them, while nearly all decaying vegetable matter favours the production of intermittent and malarial fevers. Malaria was once thought to be only of aërial origin, but the foremost investigators now attribute it also to stagnant water, containing an abundance of decaying vegetable matter.

As people gain knowledge in sanitary science, many of these impure waters are abandoned in favour of deep wells, or they are mechanically purified, generally with the happiest results in reducing the number of fever cases, or in the entire eradication of the disease. While impure water is thus productive of malaria, the fever is not directly attributable to organic matter; it is produced by a protozoon, the *plasmodium malariæ of Laveran*, which is supposed to exist in and about impure surface waters, although the organism is rarely found outside the human body. Insects that inhabit swamps and stagnant ponds may also be instrumental in propagating this fever, since the common mosquito is now regarded as the host of the malarial germ, sometimes transferring it to persons susceptible to the disease.

Far more important and dangerous, however, than mineral and vegetable matter is animal refuse, such as sewage and drainage from cesspools and privies. This not only furnishes a favourable pabulum for the growth and development of micro-organisms; but also opens an avenue to the system for admission of infection; and drinking water contaminated with sewage is intimately connected with disease, as well as objectionable from an æsthetic standpoint. There is a vast difference, however, between the infectious nature of sewage in its fresh condition and that of sewage which has undergone complete chemical change. So long as it remains as sewage, *i.e.*, retains its original nitrogenous ingredients not completely converted into new compounds, it is liable to be disease producing. Among the numerous bacteria of its earlier existence there are probably some that are harmful, and the sewage environment may so modify others as to render them pathogenic. But through the effects of dilution, precipitation, oxidation, and nitrification, these ingredients gradually disappear from contaminated water; still, we cannot rely on the disappearance of the most harmful agents at any given time, or under any given condition, for it is now well known that the self-purification of water, so far as bacteria are concerned, is much less than was once supposed.

Still, under nature's agencies, polluted water may be so improved that the factor of danger becomes inappreciably small, and it may then be drunk with the same assurance of safety that prevails when we eat or breathe. Hence it will be seen that pure and impure, like normal and abnormal, waters are distinguished only by the amount of certain constituents common to all, and it is true that nearly all natural waters have some foreign substances which would condemn them, were they present in sufficient quantity. From the nature and effect of this extraneous matter, it is evident that a drinking-water should be considered pure only when practically free from decomposing vegetation, and absolutely free from fresh products of the human body. So sanitarians have learned that it is not so much the quantity as the quality of the impurities in water that determines its suitability for drinking, and the foremost investigators uniformly condemn all waters that are in the least contaminated with fresh sewage. Even after sewage has been changed by oxidation to its final products, there may be danger from the use of water containing it, on account of its germs. This is especially true with surface waters originating in a gravel and limestone soil, for the organic matter is changed to nitrates more rapidly than the bacteria are removed. And, as typhoid fever and cholera are well known to be produced by infectious bacteria which accompany sewage, it is important, in interpreting every sanitary water analysis, to keep in mind the changes through which sewage passes under the action of the constituents of the soil.

A water is pure and wholesome when it meets all the requirements of the body in absorption and elimination, even in the most delicate constitutions. But some waters have unpleasant taste from mineral and decaying organic constituents; some have unsightly appearance from colour or suspended matter; some have disagreeable or disgusting odour; while others are so charged with inorganic salts that the kidneys are overworked in eliminating the waste products of the body. All these objectionable waters should be regarded as impure, and they are certainly unwholesome, because the system rebels against anything which is not approved by the senses of sight, taste, and smell. Such water is sometimes forced upon a community until public necessity compels it to be abandoned in favour of a pure and wholesome supply. We are safe in going still further, for, when a water is even liable to become contaminated with sewage, it should be guarded against with the same care that is exercised in dealing with the most dangerous poisons.

The diseases that are known to be produced by impure water are Asiatic cholera, typhoid fever, malaria, diarrhœa, dysentery, and some other intestinal disorders. These diseases are either the result of an irritant, or are produced by bacteria or other micro-organisms, and it seems at first thought that an investigation to determine the wholesomeness and suitability of water for domestic use should consist in searching for the immediate agents of disease. But experience shows that the bacteria

* *Engineering Magazine.*

in water are so numerous, and so resemble one another, that the harmful micro-organisms, even in the most contaminated waters, are but a small proportion of those that are present. Their determination requires the most careful study and patience, and much time, and the results are generally negative and unsatisfactory. So, in ascertaining the sanitary quality of a water, it is safer, as well as easier, to determine the organic impurities, like sewage, than the bacteria, for the pathogenic micro-organisms exist only in natural water that has, or once had, measurable quantities of organic matter. The amount of water required for a chemical and microscopical analysis is so large that any foreign matter which might exist in the general supply would, in all probability, also exist in the sample operated on; and the determination of sewage shows the possibility of accompanying dangerous micro-organisms. In sanitary water investigations it is not customary, therefore, to search for pathogenic germs, but to determine irritating substances and other associations and conditions that favour disease. This is done principally by chemical and microscopical analyses, and, in the testing of filters, by additional bacteriological examinations of the water. But a thorough investigation of a public water supply should always involve a sanitary survey of the surrounding country to determine the contaminating agencies. Sometimes also study of statistics will show a relation between death-rate and quality of water supply; and in all this work much depends upon proper interpretation of the results.

THE SANITARY SURVEY.

A sanitary survey will sometimes reveal enough pollution to condemn a water, no matter how small the amount of organic matter and how low the number of bacteria found in it. Whenever there are visible sources of filth, the water should not be used for drinking in its natural condition, especially when any of the pollution is sewage. Every season brings to our attention many cases of disease attributable to impure water, where the contamination is visible and might have been removed; and so the opinion grows stronger, year after year, that, by applying an ounce of prevention to the discovery and removal of pollution, pounds of cure would never be needed. It is always necessary to know the origin of a water that shows but little organic matter, before giving even a conditional final opinion of its quality for drinking, and the results should be compared with local standards of permissible impurity. The free ammonia sometimes found in deep wells would condemn a surface water without further study, and yet in the deep-seated water it is permissible; and the chlorine and nitrates of some mineral waters greatly exceed the permissible limits of those found at the surface. Many polluted waters found in limestone soil are free from organic matter, because this has been oxidised to harmless products; and, if we rely entirely upon our reagents and microscopes, without regard to chemical change or source, we generally pass too favourably upon the water.

In forming an opinion from the sanitary survey, it is always safe to condemn a water which shows visible contamination beyond a reasonable limit of æsthetic permissibility; yet, when laboratory methods fail to find organic matter, or its associations, in water, we are not warranted in pronouncing it good, unless we know that these have never existed in it. The most that can be said in favour of the water is purely negative. On the other hand, it is often proper to condemn surface waters, even by the sanitary survey alone; but it is unwise for a chemist to rely very much upon the investigations made by inexperienced men. The most competent investigators give an opinion only after an examination of the source of supply and the whole drainage area, made by themselves or by others equally skilled.

MILK CONTAMINATORS AND SCARLET FEVER.

Dr. Matthew Hay, Medical Officer of Health, Aberdeen, in his monthly report on the health of the city, makes lengthened reference to the prevailing epidemic of scarlet fever. The 49 cases in the present epidemic obtained, so far as can be ascertained, at least a portion of their milk supply directly or indirectly, but mainly indirectly, through the medium of one or other of five milkshops in town from a certain farmer in the country. With one milkshop there are associated 20 cases; with another, 12 cases; with a third, 9; with a fourth, 4; with a fifth, 1; and with the farmer himself, 3—the farmer supplying the bulk of his milk to milk shops and retailing only a little to private customers. The great majority of the cases occurred within a few days of each other; for example, 3 were taken ill on April 7th, 2 on the 8th, 7 on the 9th, 12 on the 10th, 5 on the 11th, 3 on the 12th, 5 on the 13th, 14th, or 15th. Some of the latter cases have probably been infected not directly by the milk but by contact with cases so infected. When allowance is made for a varying period of incubation in the cases, it would appear as if perhaps half of the cases, or more, had been infected from a single day's infection about the 5th or 6th of April.

The simultaneous outburst of scarlet fever among the customers of more than one dairy was against the milk being simultaneously but separately infected in the various milkshops in town. Such a coincidence of infections is in the highest degree improbable, although to make sure, the persons and families associated with the carrying on of the milkshops were examined, but nothing was found. The conditions clearly pointed to the infection of home milk supply common to all the milkshops. On investigation it was found that one farmer did supply all the suspected dairies with the whole or a portion of their milk, and that all the milk thus supplied came from his own cows and was brought into town daily in his own cart, and it was further found that the milkshops in connection with which the outbreaks arose were the only milkshops supplied by this farmer. The farm was visited as soon as there was sufficient ground for suspecting it, and with the assistance of the county Health Officers, which was most fully and ungrudgingly given, a careful examination was made of the persons employed or living on the farm premises, and a simultaneous inspection of the cows was made by the county Veterinary Inspector. No history of illness could be elicited from any servant or member of the family, and beyond some slight symptoms of sore throat and the like, which were

consistent with a recent very mild attack of scarlet fever, but not conclusive of it, nothing definite was discovered. The cattle were pronounced by the veterinary surgeon to be in good health, and he specially examined the udders and teats for traces of disease, in view of the fact that on one or two occasions it has been asserted—in my opinion, on insufficient grounds—that a milk outbreak was due to infection from cows. There remained the possibility that the milk had been infected in transit to the town, but as the milk was in cans or other closed vessels, and as the farmer himself alone travelled with the milk cart, this mode of infection seems unlikely. There is no doubt in my own mind, from a full consideration of all the facts, that in spite of the practically negative result of the inspection of the farm, this farmer's milk was the source of the epidemic. The probability is that we had to deal with the occurrence in the farm household of one of those exceedingly mild attacks of scarlet fever which happen so often now-a-days, and which frequently go quite unnoticed. Nothing more may be observed than a slight sore throat for two or three days, with slight unwellness, and if it occurs in a child the parents may not have noticed it, and the child, when questioned about it a few days later, is found to have forgotten about it. In certain of these cases even desquamation, which comes on in the later stages of the disease to aid the diagnosis, may be wanting, or so slight as to have escaped observation. I attach no blame to the farmer in this outbreak. The outbreak, however, enforces the need of very careful attention to the state of health of persons in or about dairies. Sore throats should always be regarded with the greatest suspicion—they may be symptomatic of scarlet fever or diphtheria—and, if at all practicable, persons so suffering, or persons who feel fevered, should not be permitted to milk cows or to handle or go near the milk. Young children, who are so susceptible to infectious diseases, and who are so often suffering from one or other of infectious diseases, should never be allowed to take part in a dairy in handling or washing milk vessels or in carrying milk, and should, indeed, be kept strictly outside the milk-house. Fortunately, all the cases of fever in the present outbreak have been mild, and in some instances as mild as the case from which the infection may have sprung. This, perhaps, may be held to support the theory of infection from an unnoticed mild case. It has reproduced its own type. A curious point in the outbreak is the age of the persons attacked. In the vast majority of ordinary cases of scarlet fever the age of the patient is under 14 years, and is usually about five to ten. In the 49 cases of the outbreak, only 17 were under 14 and of the remaining 32 a large number were over 20 years. It is also worthy of note that of the 32 patients above 14, 21 were males and 11 females. As most of the cases were removed to the city hospital, the quite exceptional proportion of grown-up patients there has been most noticeable, especially in the male wards. There remains only to be added that the farmer, as soon as the facts of the outbreak were brought to his notice, agreed to suspend his milk supply for two days until arrangements were made for procuring a perfectly fresh staff from the outside to carry on the dairy work of his farm.

Sanitary Inspectors' Associations.

SCOTLAND.

THE annual meeting of the North-Eastern Branch of the Sanitary Inspectors' Association of Scotland was held in Aberdeen on Saturday, the 21st inst. Mr. Anderson, C.E., Sanitary Inspector, Forfarshire, chairman of the branch, presided. There was a fair attendance. The secretary's report of the year's work was laid before the meeting, and was considered satisfactory. The following members were elected as office bearers for the ensuing year:—Chairman, Mr. Anderson, Forfarshire; vice-chairman, Mr. Cumming, Carnoustie; secretary and treasurer, Mr. Forbes, Aberdeen; other members of Committee, Messrs. Mackintosh, Banffshire; Graham, Kincardine; Milne, Elgin County; and Turriff, burgh of Elgin. Mr. Cumming, Carnoustie, read an interesting paper on water supply. He dealt with the various sources of supply—from rain, springs, wells, rivers, and upland surface water—with the qualities and causes of pollution of these different classes of supply, and the methods of purification and the qualities supplied to different towns. After a discussion, on the motion of Mr. Cameron, president of the Sanitary Inspectors' Association, seconded by Mr. Mackintosh, Banffshire, and supported by Mr. Anderson, chairman of the branch, a hearty vote of thanks was accorded to Mr. Cumming. A proposal by Mr. Anderson that the branch should visit some place of interest in the autumn was then considered, after which the meeting terminated.

THE MEDICAL AND SURGICAL EXHIBITION.

THIS exhibition was opened on Tuesday in the Queen's Hall, Langham-place. The object aimed at by the promoters is to bring before the profession and its auxiliaries the most recent results of scientific research in the mitigation of pain and fighting the ravages of disease. There was a formal opening by the president—Mr. F. Weiss—who emphasised the fact that last year's show was visited by 4260 of those for whom it is intended. One of his own inventions for cauterisation by burning ether is one of the newest discoveries in surgical art. Through a warmed and regulated tube framed like a pencil case the cauterising agent is applied with effect for the removal of tumour. Several of the stalls are bright with highly-polished instruments. Others are stocked with medicated foods, notably breadstuffs prepared to counteract exhaustion from diabetes.

Malt extracts, which are now very much in vogue, gives as the latest invention a kind of stout made from malt only by Mr. Hoff, claiming to be a powerful tonic containing only 2½ per cent. of alcohol. It is certainly pleasant and refreshing. Sterilised and humanised milk figures largely, and so too do the various essences of beef. Extracts of the essential properties of vegetables are likewise in evidence, and a wide variety of lozenges, tabloids, tonic wines, and miscellaneous preparations, which are at all events freely submitted to the test of qualified judgment.

General News.

LEEDS.—The erection of Turkish baths by the Corporation is under discussion.

BANBURY.—The Town Council has decided upon extensive improvements of the public baths.

ST. MAWES.—A conference has been arranged by the Truro Rural District Council with reference to the practicability of getting a water supply.

PENZANCE.—At a recent Town Council meeting Mr. Mansergh's report on the water supply of the town was read. It recommended a scheme estimated to cost £74,000.

UTTOXETER.—The Urban District Council has called in Mr. J. E. Willcox, C.E., of Birmingham, to advise and report on a scheme for augmenting the supply of water to the town.

HASTINGS.—The quarterly report of Dr. A. Scarlyn Wilson, Medical Officer of Health, gives, after deducting the deaths of strangers in public institutions, a total number of 333 deaths in the borough, giving a death-rate for the period mentioned of 18·56 per 1000.

PRESTON.—Dr. Pilkington, Medical Officer of Health for Preston, has issued his annual report. Out of every 1000 children born in Preston during 1897, 263 died before attaining the age of twelve months. In none of the other thirty-three large towns was this enormous death-rate exhibited.

NOTTINGHAM.—The Health Committee of the Corporation has visited Leyton for the purpose of inspecting the "destructors" at work there. Upon its experiences here as well as at Sheffield and Bradford the Committee will prepare a report to the Council, and make certain recommendations.

BIRMINGHAM.—A meeting of the Finance Sub-Committee was held recently at the Council House, under the presidency of Councillor Johnstone. The hon. treasurer reported that the expenses of the Congress were estimated to amount to at least £1500. Contributions to the guarantee fund had only been received from 302 persons, and it was decided that a further appeal should be made for additional guarantees.

ABERDEEN.—The City Hospital Committee of the Town Council has had under consideration the proposed extension of the administrative block at the hospital. Mr. Rust, City Architect, submitted amended plans showing accommodation for nurses and servants on the main block, and also showing the extension of the north wing of the present reception block. The total cost of the extensions is estimated at £4650. The Committee generally approved of the plans.

ST. SAVIOUR'S, SOUTHWARK.—"Ice cream" as sold by itinerants in the streets has been considered by the Sewers and Sanitary Committee. After thoroughly investigating the matter, the Committee report that it is extremely difficult to proceed against vendors of deleterious ice cream under the existing Food and Drugs Act. A letter is to be sent to the Home Secretary calling attention to the fact that ice cream is largely sold in the streets of London to children, and urging upon him the desirability of the Act being amended so as to include the sale thereof.

LEEDS.—The Insanitary Areas Sub-Committee of the Leeds Corporation is making progress with the work necessary for the removal of the insanitary area at Camp Field, Holbeck. Nearly all the property which it is proposed to demolish has been bought, and the Sub-Committee has accepted tenders for the erection of ten dwelling-houses in Derwent-avenue, near Bath-road, Holbeck, at a cost of £1815. These houses are intended for the accommodation of persons who will be displaced by the carrying out of the scheme, the Local Government Board requiring that provision should be made for them by the Corporation.

LOWESTOFT.—The new children's wing at Lowestoft Hospital has been opened. It has been designed in character with the existing building, and is connected therewith by a covered way paved with tiles. The large ward is arranged for six cots. The floor is laid with polished maple blocks, and the walls finished with Parian cement. The ward is heated by means of Shorland's central ventilating stove, and is lighted by incandescent burners. There is also a smaller ward for two beds, with a separate entrance, so that, if occasion requires, it may be used as an isolation ward. There are separate lavatories and bath-rooms to the wards, and between them is a nurses' duty-room.

WOODFORD.—It is proposed to erect a cottage hospital at Woodford. The site selected occupies a corner position in Broomhill-walk, facing the Green. The plans provide on the ground floor a male and a female ward with a nurse's room between. Each ward will contain three beds, but the accommodation is sufficient for six beds each. In the female ward will be placed the children's cots. Opposite to the operating-room is the matron's bed-room and sitting-room. The kitchen and domestic offices are placed at the rear. Beneath the kitchen are the coals and wood store, together with a heating chamber. The first floor provides for one male and one female paying patient, servants' bedroom (two beds), nurses' bedroom, bath-room, &c., and store-rooms. It is proposed to carry out the elevations in red brick with stone dressings, and roofed with Broseley tiles.

Personal.

MR. A. BLACKMAN has been appointed Electrical Engineer under the Poplar District Board.

MR. P. COLEMAN has been appointed Medical Officer for the eighth district of Tendring union.

MR. WALTER RIDLER has been appointed Inspector of Nuisances for the borough of Tewkesbury.

MR. A. CHAWNER has been appointed Medical Officer for the Clay-lane district of Chesterfield union.

MR. ANTHONY J. METCALFE has been appointed Inspector of Nuisances for the urban district of Masham.

THE Local Government Board has sanctioned the appointment of Mr. G. D. Risdon as Medical Officer for No. 2 district of the Wells union, at a salary of £90 per annum.

MR. R. W. REED has been appointed Surveyor and Sanitary Inspector for the borough of Lostwithiel.

MR. J. BOLTON, of Heywood, has been appointed sewage works manager under the Heywood Corporation.

MR. ARTHUR BOULTON has been appointed Medical Officer of Health for the urban district of Woodhall Spa.

THE salary of Dr. Hamer, Assistant Medical Officer to the London County Council, has been raised from £600 to £700 per annum.

MR. THOMPSON has been appointed Inspector of Nuisances for the urban district of Lye and Wollescote, at a salary of £40 per annum.

DR. BRABYN has been appointed Medical Officer of the south-western district of Wimbledon, and Dr. Hemingway of the south-eastern district.

DR. H. HEMSTED has been reappointed Medical Officer of Health for the Whitchurch Board of Guardians, at a salary of £66 10s. per annum.

MR. W. W. BRUCE, L.C.C. for Bow and Bromley, has been elected a Lee Valley Drainage Commissioner in the place of Mr. Arthur Humphrey.

DR. C. V. DINGLE has been appointed Medical Officer for the Corporation of Middlesbrough, in room of the late Dr. Malcomson, at a salary of £350 per annum.

MR. ARTHUR B. HOWE, M.R.C.S., and L.R.C.P., has been appointed Medical Officer for the district of Claygate (Kingston union) in succession to Dr. Maclaran, resigned.

MR. ROBERT HILL has been appointed Nuisance and Water Inspector for the urban district of Chesham, at a salary of £75 per annum, in room of Mr. F. Dawkins, resigned.

THE Local Government Board has sanctioned the appointment of Dr. A. H. Ransome as Medical Officer of Health for the urban district of Southgate, at a salary of £75 per annum.

THE Local Government Board has sanctioned the reappointment of Dr. Evers as Medical Officer of Health for the urban port district of Faversham, at an increased salary of £10 per annum, also the reappointment of Dr. Evers as Port Medical Officer, and Mr. W. Evernden as Port Sanitary Inspector.

THE following announcement will be of interest to a large number of our readers :—We are informed that a marriage has been arranged between Miss Jane S. Wilson, eldest daughter of Mr. John Wilson, M.P. for the Govan division of Lanarkshire, and Dr. W. J. Collins, D.L., J.P., late Chairman of the London County Council.

Sewerage Schemes.

[TO MUNICIPAL ENGINEERS AND SURVEYORS.—The Editor will be pleased to receive items for publication relating to sewerage schemes projected or inaugurated, together with explanatory diagrams or photographs. The former should be drawn and lettered in black ink.]

THE Local Government Board has refused its sanction to the borrowing of £4500 for the Little Common drainage scheme, Oldbury.

THE Plympton Rural District Council has decided to apply for a loan of £3500 for the joint scheme of drainage for Egg Buckland and Compton.

THE Barton Rural District Council has received the sanction of the Local Government Board to the loan of £1130 for the Flixton sewage disposal works.

THE Rowley Regis District Council has decided to borrow £4000 from the Birmingham branch of the Bank of England, being part of the sum of £25,000 to be borrowed by the Council for sewerage purposes.

AT a recent special meeting of the Royton Urban District Council it was decided to borrow an additional £22,416 for sewerage purposes. The special permission of the Local Government Board has been obtained for the loan.

THE Town Council of Brighouse has decided to accept the tender of Messrs. Hughes and Lancaster for the supply of machinery at the sewage outfall works, the cost to be £1569. The total amount spent on the sewage scheme is reported to be £59,575 9s.

THE Wakefield Rural District Council has decided to fence the boundary of the sewage works at an estimated cost of £95, and to ask the Local Government Board for the inclusion of this sum in the estimate for £4000 in lieu of the sum therein included in respect of subsoil drains.

A SPECIAL meeting of the Mansfield Woodhouse Urban District Council was held recently, under the presidency of Mr. W. W. Hall, to receive and consider a report from the engineers, Messrs. Hodson and Son, Loughborough, setting forth a scheme to deal with the sewage of the village. A letter addressed to the chairman from the engineers was read. A tracing of the land which could be adapted for the purification of the sewage was enclosed. The communication asked Mr. Hall upon what terms he would lease the land to the Council for sewage disposal purposes for a period of not less than thirty years, the terms to include the right to lay the main sewer across the land. Bearing in mind Mr. Hall's objection to the treatment by broad irrigation, they had not renewed the original proposal to take the land around the bailiff's house. Ten acres of land would be required, upon which deposit tanks would be built for the purpose of arresting the solids, and the treatment of the sewage would be through bi-bacterial filters. As an alternative scheme Messrs. Hodson asked Mr. Hall if he would lease the Council a field of 2557 acres in extent, to be utilised in connection with a scheme comprising the erection of pumping plant, &c. The sewage, after being pumped, would be treated on the broad irrigation principle, over two fields of 15½ acres belonging to the Duke of Portland, if they could lease the land from his Grace. A resolution was adopted instructing the Clerk to write to the engineers for information as to the cost of adopting either scheme.

THE Carlisle City Council has instructed the Surveyor to prepare plans, &c., of a bacteriological filter to deal with a portion of the town's sewage on the Dibdin principle.

THE Loughborough Town Council has resolved that application be made to the Local Government Board for a loan not exceeding £2500, to meet the costs of sewerage works.

AT a recent meeting of the Heath Town District Council the sewerage engineer, Mr. R. E. W. Berrington, reported that the work of the sewerage scheme was proceeding satisfactorily. The question of water carriage versus pail system of domestic sewerage would shortly be considered.

THE Medical Officer of Health for Chipping Sodbury, in his annual report, states that the sewage works at Wickwar were so far completed that the whole of the sewage from the land and the two breweries was, in the early part of the spring, cut off from the old inlets to the brook, in which it has for so many years created such a nuisance. The experience which has been acquired since then has shown that the resources provided for dealing with the sewage at the outfall are not sufficient to give a satisfactory result, and that without an enlargement of them the nuisance will only be shifted from the brook to the land on which the sewage is allowed to flow.

Lighting.

THE Kidderminster Town Council has decided that the town be lighted with electricity.

THE Johnstone Corporation has decided to proceed with important extensions to its gasworks.

THE estimate for the proposed improvements and extensions at the Burnley Borough Gasworks is £6510.

THE General Purposes Committee of the Birmingham City Council has decided to recommend the purchase by the Corporation of the business of the Birmingham Electric Supply Company, the suggested terms being the present market price of the £5 share, viz., £10 10s.

TO cope with the enormous increase in the consumption of gas in the district of Leigh, caused by the rapid increase in the population, the Urban District Council has decided to apply to the Local Government Board for sanction to borrow £25,000 for gasworks extensions, and £10,500 for proposed electricity works.

THE profits of the gas department of the Lancaster Town Council for the past year are reported to be £1080.

MR. A. BLACKMAN, of Aberdeen, has been appointed resident electrical engineer to the Poplar District Board of Works, which is about to effect an electric lighting installation.

MR. WRIGHT, the electrical engineer to the Brighton Corporation, has been engaged by the Whitechapel District Board of Works to advise as to an electric lighting installation for that district, the Board having already obtained an electric lighting Provisional Order and a site for the erection of a generating station.

AT a recent meeting of the Whitechapel District Board the Chairman informed the Board that Messrs. Dyson, the Board's parliamentary agents had written the Clerk informing him that the Board of Trade had communicated to them the fact that the Electric Light and Brush Company had withdrawn their application for an order to light the district with electricity. The Special Committee reported having visited various installations, and spoke very highly in favour of the system at Brighton.

AT the meeting of the Hampstead Vestry last week Mr. A. P. Johnson, the clerk, reported that the profits on the Vestry's electric lighting undertaking for the past year had exceeded all expectations. The revenue for the year amounted to £8081 0s. 9d. They had paid £2980 8s. 3d. interest on capital, and they had also repaid £1187 12s. 10d. instalments of capital, leaving the net profit of £3905 3s. 4d. Sir Henry Harben, the chairman, pointed out that if the Vestry were a trading corporation, and had not to repay the capital by instalments, the profits for the year to rank as dividends would exceed £5000. The total amount of capital expended up to the present is £100,167.

THE Sheffield Municipal Authorities have just had an unusual experience in civic administration. Some time ago the City Council unanimously decided to acquire the undertaking of the Electric Light and Power Company. Terms were arranged, and the usual meeting of the ratepayers called to approve the promotion of a Bill for the purpose. The whole subject, says the *Engineer*, was regarded as a foregone conclusion, and very few ratepayers turned up. The result was that a mere handful of electricians in the city outvoted the City Council, and, it may be added, the City Authorities had to take a poll. The poll was taken on Monday, and the votes counted on Tuesday, when the result was:—For Corporation purchase, 28,130 votes; against, 1965; majority for purchase, 26,155. The poll cost £1000. The moral is that Public Authorities should never be too sure of success, or under estimate the power of those whose private interests may be affected by municipal enterprise.

HOW ADULTERATION OF DAIRY PRODUCE IS DEALT WITH IN FRANCE.

VERY slow progress and very feeble attempts are made in this country towards protecting consumers against dairy produce adulterations, which are undoubtedly one of the worst forms of food adulteration which the Legislature has to contend against.

In France they are putting forth greater efforts to check this growing evil than we are, and the effects of the new French margarine law will be watched with great interest by the dairy farmers of this country.

It appears that the main object of the new law is to prevent fraud by establishing a distinction between butter and margarine so clear that the purchaser cannot be deceived as to the character of the product offered to him.

Butter is defined as the product of cream or milk alone, with or without salt. The introduction of any other substance into butter renders it legally margarine. In order to render the two commodities entirely distinct in appearance, the colouring of margarine is entirely prohibited. Moreover, it is sought to establish a complete separation between the two industries and the two trades, and even in markets the two commodities are to be sold in separate divisions. Then there are stringent regulations as to the character and condition of substances to be used in the manufacture of margarine. This last is a very necessary provision, in order to protect people from being induced to eat most objectional compounds, but it appears to the writer that the great difficulty will be to enforce such regulations.

The magarine industry has grown to be a very lucrative business, and there is a very powerful moneyed influence behind it in this as well as in other countries. Yet the mixture of butter with foreign fat is practised solely for the purpose of increasing the value of fats, and some of them—the very cheapest and most objectionable fats—by the addition of good butter, so that it may take the place of butter to a large extent, and that at a relatively higher price; or for the purpose of passing it off in the market as butter.

For these reasons this practice ought to be everywhere regarded as an attempt to carry on a lucrative industry at the expense of the dairy industry, and of the less wealthy portion of the public.

Law Cases.

THE SMOKE NUISANCE IN GLASGOW.

A CASE of considerable interest to hotel-keepers has just been decided by Police-Judge Murdoch at the Glasgow Central Police-court. Mr. Charles Ulbrich, 569, Sauchiehall-street, manager of the Grand Hotel Company, was charged with having, on April 22nd, used a furnace (the same not being a household fire) so that smoke issued therefrom. He pleaded not guilty. The evidence for the prosecution was that two policemen watched the chimney of the hotel, which is an ordinary one, on the top of a four-storey building. Black smoke issued continually for seven, five, and five minutes—in all, seventeen minutes within an hour. There is a furnace and an upright boiler used for supplying hot water to the bath-rooms and the kitchen.

Mr. George Neilson, Procurator-Fiscal, contended that this was not a household fire, but a furnace in a commercial institution. He asked his Honour not only to convict, but to impose a smart fine.

An agent contended, on behalf of Mr. Ulbrich, that this was a household fire, and therefore exempt from the Act. They might as well say that a house in which lodgers were kept was a commercial institution.

Mr. Young, the assessor, said that the late Stipendiary Gemmel convicted the Western Club of a similar offence.

The agent said that this was a house within the meaning of the Act, and all its fires were household fires, from which smoke might be allowed to come to any extent. Formerly there were two small boilers, but in order that the supply of hot water might be improved this large boiler was put in lately.

The Magistrate said that they could not call this a household fire; it was a separate fire for a separate purpose.

The agent said that this was simply a hot-water boiler.

Mr. Neilson said that manufacturers wanted steam, and the accused wanted hot water; it was the same thing.

The Magistrate said he could not hold that this was a household fire. He therefore fined the accused 10s. 6d.

DISEASED MEAT AS FOOD.

THE matter of Rendell *v.* Hemingway came before the Court of Queen's Bench last week upon a case stated by the Stipendiary Magistrate at Bradford, and involved an important question under the Public Health Act, 1875.

Mr. TINDEL ATKINSON, Q.C., and Mr. LONGSTAFF appeared for the appellant; and Mr. LAWSON WALTON, Q.C., Mr. CARSON, Q.C., and Mr. CHITTY for the respondent.

The appellant carried on the business of a draper in town, and was proceeded against under the Act, for having on his premises the carcase of a sheep which it was said was unfit for human food, and was convicted and fined £5, and ordered to pay £4 18s. for costs. The Magistrate found, as a fact, that the sheep was intendad by the appellant for the food of himself, his family, servants, and workpeople, and that it was not exposed or deposited for sale, or being prepared for sale. The appellant contended that as it was not exposed or intended for sale, no offence had been committed, but the Magistrate thought he was bound by the decision of Mr. Justice Hawkins and Mr. Justice Stephen in the case of "Mallins *v.* Carr," and convicted.

The Court quashed the conviction, being of opinion that unless the meat was, under Section 116, which created the offence, exposed or intended for sale, or deposited for sale, no offence was committed, and that the case relied upon by the Magistrate did not apply, as the facts proved they were entirely different.

Conviction quashed accordingly.

Notes and Queries.

[Subscribers have the privilege of obtaining advice in this column on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed to THE EDITOR, "Notes and Queries," THE SANITARY RECORD, 5, Fetter-lane, London, E.C.

NOTE.—If an answer be required immediately, a stamped addressed envelope must be enclosed, when we will endeavour to furnish a copy of the answer by post, as owing to the large number of queries received we cannot guarantee the insertion of a reply in the succeeding issue.

1097.—STREET: OWNERS FENCING PART OFF: DEDICATION.—"Constant Reader" writes:—"In our district we have a street one end of which is a *cul-de-sac*. The owners of the houses near the blocked end of the street have fenced off the ground opposite their houses, the fence extending across the street. Has the Local Authority any power to compel the owners to remove the fence, the street not being dedicated?"

Answer.—If the public have acquired an easement of passage over the part of the street now barricaded off the owners will not be enabled to maintain the obstruction, and they may be required by the Local Authority to remove it. Although the street may not have been adopted as a public highway, it may, nevertheless, have been dedicated to the public, notwithstanding that it was repairable by the abutting owners. It would have been of assistance if we had been furnished with particulars as to how long the street had been open to the public prior to its being barricaded off, and whether there was an evidence of dedication to the public use.

1098. — UNOCCUPIED HOUSES A NUISANCE: PROCEEDINGS.—"G. H." writes:—"In my district there are a number of unoccupied houses which are in a dilapidated condition, and which are used as urinals, closets, &c., and are in a very offensive condition. Will you please advise as to what steps ought to be taken to have the nuisances abated?"

Answer.—If it can be proved that there is a nuisance on the premises, or if the premises are a nuisance or injurious to health, proceedings may be taken under Secs. 91 to 94 of the Public Health Act, 1875, to have the nuisances abated. Proceedings may in the alternative be taken under the Housing of the Working Classes Act, 1890, Sec. 32 (2), for the express purpose of having them closed.

1099.—OVERCROWDING IN COTTAGES: NUISANCE: PROCEDURE.—"A. P." writes:—"In my district there are many cottages which are apparently overcrowded. Will you please inform me what powers the Local Authority have to deal with cases of overcrowding in such circumstances?"

Answer.—Sec. 91, Sub-sec. 5, of the Public Health Act, 1875, provides that any house or part of a house so overcrowded as to be dangerous or injurious to the health of the inmates shall be deemed to be a nuisance liable to be dealt with summarily, and proceedings should be taken under Secs. 94—96 of the Act.

1100.—NUISANCE FROM CESSPOOL OVERFLOWING.—"D. O. G. C." writes:—"Will you kindly tell me who is responsible for the abatement of a nuisance caused by a cesspool overflowing, the cesspool receiving the drainage from a block of three cottages. The cesspool is not on the land of the owner of the cottages. I have served a notice on the owner of the houses, by whose act, default, or sufferance the nuisance arises, but he has only cleansed the cesspool, and has not taken any steps to remedy the nuisance beyond this."

Answer.—In Meader *v.* West Cowes Local Board (61 L. J., ch. 561; L. R., 3 ch., 18) it was held that a cesspool was not part of a sewer, and that the overflow pipe leading therefrom was not a sewer for which the Board could be made responsible. The Local Authority should require the owner of the cottages to cleanse the cesspool at stated periods, or, if the Local Authority have provided their district with sufficient sewers, he should be required to abate the nuisance by connecting the drains of his houses to the sewers.

1101.—RAIN-WATER CISTERNS: PURIFICATION OF WATER.—"Cambrian" writes:—"I send you sketch showing a rain-water cistern of 80 gallons capacity, and a clean water cistern of 80 gallons capacity, also a small cistern or cylinder to receive or be filled up with a medium for cleansing the rain water for bath supply only. Please advise what material or medium can be used in cistern or cylinder for cleansing the rain water on its passage from cistern A into cistern B for supply to bath. Kindly give size of cistern B."

Answer.—The sketch submitted to us, and not reproduced, cannot be satisfactorily adopted in practice. The querist should obtain Greenwell and Curry's "Rural Water Supply," and study the matter more thoroughly. He might adopt Roberts' rain-water separator to exclude dirt, &c., from roofs, from entering the cistern, or if he were to communicate with some of the manufacturers of filters who advertise in our pages they would no doubt advise him. We regret we are unable to further advise on the information given us.

1102.—CORRUGATED IRON BUILDINGS: BYE-LAWS AS TO NEW STREETS AND BUILDINGS.—"Yorkshire" writes:—"The bye-laws as to new streets and buildings of this Council provide that 'every person who shall erect a new building shall cause such building to be enclosed with walls constructed of good bricks, stone, or other hard and incombustible materials, properly bonded and solidly put together.' Will you kindly advise whether corrugated iron buildings could be approved as being in accordance with the bye-law?"

Answer.—No. Such buildings could not be approved as in conformity with this bye-law. The words "other hard and incombustible material" should be read in conjunction with the clause "good bricks or stone," which implies materials of a similar substance, and precludes the use of corrugated iron. Moreover, the clause as to thickness of external and party walls provides that the least limit of thickness must be 9in., and it could not be maintained that a wall formed of corrugated iron could comply with this clause.

1103.—THE KNACKERS ACT, 1786: LICENCES REQUIRED.—"T. W. H." writes:—"Will you please advise me on the following:—A. advertises that he removes dead horses or any other kind of cattle on the shortest notice, also that gentlemen and others can have slaughtered on their own premises old favourite nags or other horses, if required. Does this constitute the carrying on of the business of a knacker? Should the premises be registered as a knacker's yard, where the flaying and cutting up is done?"

Answer.—The Knackers Act, 1786, which is now enforced by District Councils, as provided by Sec. 27 of the Local Government Act, 1894, provides that "no person or persons shall keep or use any house or place for the purpose of slaughtering or killing any horse, mare, gelding, colt, filly, ass, mule, bull ox, cow, heifer, calf, sheep, hog, goat, or other cattle, which shall not be killed for butchers' meat, without first taking out a licence for that purpose at the General Quarter Sessions," &c. (now the District Council), of the district wherein such slaughtering-house or place shall be situate. If the person slaughters the animals, and removes them to his yard to complete the slaughtering process, it appears to us that he is carrying on the business of a knacker, and a licence should be obtained for the yard where such is carried on. It may be observed that by 7 and 8 Vict., c. 87, s. 1, such licences are in force for one year only.

1104.—Disinfecting Powders: Composition of Required.—"W. H. C." writes:—"My Authority has for several years made its own carbolic disinfecting powder. We use Crich lime as a base, and mix commercial carbolic acid, 97 to 99 per cent., and carbolic disinfecting fluid in equal proportions with it, the whole being well screened and mixed. Will you kindly inform me what changes the lime and acid undergo, and whether the powder is of any real use as a disinfectant? The powder is strongly alkaline in reaction."

Answer.—As we do not know what is the composition of Crich lime, we are unable to give our correspondent the required information. We may, however, state that sulphate of lime, on account of its power of absorbing ammonia, is a deodorant, but cannot be regarded as an antiseptic; carbonate of lime and other insoluble metallic salts are inert. Quicklime (CaO) acts only as an absorbent, while slaked lime, or calcium hydrate, $Ca(OH)_2$, absorbs acid vapours and sulphuretted hydrogen, and therefore acts to a certain extent as a deodorant. Our correspondent should procure Dr. Rideal's "Disinfection and Disinfectants," 12s. 6d., which will be found to give him much useful information on the subject.

1105.—Construction of Bridge in Concrete.—"Inquirer" writes:—"It is just possible I may have to build a small concrete culvert or bridge over a brook in my district in the near future. Would you kindly tell me (1) What is the least rise I can give to a cement concrete arch, say, 7ft. wide between walls? (2) What thickness ought the side walls to be about 2ft. 6in. high? (3) What proportion of cement to ballast would you use? (4) Would it strengthen it to put any irons in the arch, say, ½in. square, bent over the same shape as the centre? (5) Could you name a book on concrete works, where obtainable, and the price?"

Answer.—(1) and (2) It is necessary to study the special features of each case before determining on the thickness of walls or arches, and also as to the rise to be given to any arch. Attention must be directed to the weight which the bridge will have to carry, whilst the nature of the ground must also be taken into consideration. (3) The concrete for the walls should be composed of six parts of ballast to one part of Portland cement, whilst that for the arch should be composed of four parts ballast to one part of Portland cement. If the concrete is to be made impervious, the extrados and soffit of the arch and also the inside of the walls must be rendered with Portland cement mortar, composed of two parts of clean sharp sand to one part cement. (4) One of the best and simplest methods of strengthening a concrete arch is to build it on the "Monier" system. This is a framework of wrought iron wire netting embedded in the concrete, and is supposed to possess advantages over the solid bar method of construction, whereby any expansion or contraction can be better distributed. (5) We recommend Potter's "Concrete: Its Use in Building," &c., price 7s. 6d., as an excellent book for the purposes required by our correspondent. The book may be obtained from the Sanitary Publishing Company, 5, Fetter-lane, London, E.C., post free, on receipt of the published price. Waddell's "Design of Ordinary Highway Bridges," price 17s., is also an excellent book.

INSURANCE.

THE MUTUAL LIFE INSURANCE COMPANY OF NEW YORK.

PRESIDENT:
RICHARD A. McCURDY.

Policy-holders in the "Mutual" enjoy the advantages of

SECURITY—
Assets, 1897.. .. exceed £52,000,000

Vacancies.

BUILDING AND DRAINAGE INSPECTORS (LONDON, N., June 13th).—For the Hornsey Urban District Council. Salaries, £160 per annum. Mr. E. J. Lovegrove, engineer and surveyor, Council's Offices, Southwood-lane, Highgate.

BUILDING INSPECTOR (LONDON, W., June 11th).—For the Ealing Urban District Council. Salary, £2 10s. per week. Mr. Wm. Ruston, clerk, Public Buildings, Ealing, W.

BUILDING AND SANITARY INSPECTOR (BINGLEY, June 14th).—Mr. R. Armistead, clerk, Town Hall, Bingley.

BUILDING INSPECTOR (SWINDON, June 7th).—For the Swindon New Town Urban District Council. Salary, £130 per annum. Mr. Henry Kinneir, clerk, Public Offices, Swindon.

CLERK OF WORKS (WARLINGHAM, SURREY, June 14th).—For the Croydon Town Council. Salary, £4 4s. per week. Application forms to be obtained at the Town Clerk's Office, Croydon, and to be sent to Mr. E. Mawdesley, town clerk, Town Hall, Croydon.

COUNTY SURVEYOR (LEWES, June 24th).—For the Roads and Bridges Committee of the East Sussex County Council. Salary, £400 per annum. Mr. F. Merrifield, clerk, County Hall, Lewes.

CITY ENGINEER (CAPE TOWN, June 15th).—For the Corporation of the city of Cape Town. Commencing salary, £800 per annum. Messrs. Davis and Soper, 54, St. Mary-axe, London, E.C.

CLERK OF WORKS (BOLLINGTON, NEAR MACCLESFIELD, June 4th).—For the Urban District Council. Salary, £3 3s. per week. Mr. W. H. Radford, civil engineer, Angel-row, Nottingham.

CLERK OF WORKS (FARSLEY, June 6th).—For the Urban District Council. Salary, 50s. weekly. Mr. J. Iles, J.P., chairman of the Council, Farsley, near Leeds.

CLERK OF WORKS (STOWMARKET, June 13th).—For the Urban District Council. Salary, £3 3s. Messrs. Pollard and Tingle, 31, Old Queen-street, Westminster.

CLERK OF WORKS (NEATH, June 7th).—For the Rural District Council (Highway). Salary, 36s. per week. Application forms can be obtained from Mr. D. M. Davies, engineer and surveyor, 58, Water-street, Neath.

DISTRICT SURVEYORS (LONDON, S.W., June 9th.)—For the London County Council. Application forms, to be obtained at the County Hall, Spring-gardens, must be addressed to the Clerk of the London County Council, Spring-gardens, S.W.

ELECTRICAL ENGINEER (ABERDEEN, June 17th).—For the Town Council.—The salary will be £225 per annum. The Town Clerk.

ENGINEER, &C. (BIRMINGHAM, JUNE 13th).—For the Birmingham, Tame, and Rea District Drainage Board.—Salary, £3 3s. per week. Also an Assistant Surveyor. Salary, £2 10s. per week. Mr. J. Knight, engineer, Council House, Birmingham.

Contracts Open.

The dates given below are the latest up to which tenders can be received.

BURY ST. EDMUNDS.—June 13th.—Plant.—Mr. F. Hastings Medhurst, B.Sc., M.I.E.E., consulting engineer to the Corporation, Westminster-chambers, 13, Victoria-street, S.W.

PRINCES RISBOROUGH (NEAR HIGH WYCOMBE).—June 8th.—Sewers.—Messrs. John Taylor, Sons, and Santo Crimp, civil engineers, 27, Great George-street, Westminster.

STOCKPORT, June 8th.—Sewering.—Mr. John Atkinson, A.M.I.C.E., borough surveyor, St. Petersgate, Stockport.

CITY ENGINEER (CAPE TOWN, June 15th).—For the Corporation of the City of Cape Town. Commencing salary £800 per annum. Messrs. Davis and Soper, 54, St. Mary-axe, London, E.C.

TOTNES.—June 20th.—Sewage Works.—Mr. W. F. Tollitt, borough surveyor, Gate House, Totnes.

HALE (CHESHIRE). — June 21st. — Sewers. — Mr. J. M'D. M'Kenzie, 7, Market-street, Altrincham.

POULTON-LE-FYLDE (LANCS).—June 6th.—Sewering.—Mr. Thomas Gornall, Holly Bank, Poulton-le-Fylde.

TOTTENHAM. — June 7th. — Dust Collection. — Mr. Edward Crowne, clerk, 712, High-street, Tottenham.

CHESTER-LE-STREET.—June 8th.—Drainage Work.—Mr. H. Webb, surveyor, 15, Lumley-terrace, Chester-le-Street.

HEMSWORTH (YORKS).—June 8th.—Scavenging.—Mr. J. Beckitt Simpson, Ackworth.

CROMER.—June 10th.—Sewers.—Mr. A. F. Scott, Church-street, Cromer.

SOUTHAMPTON.—June 14th.—Sewerage Works.—Mr. W. B. G. Bennet, borough engineer.

ASHBY-DE-LA-ZOUCH.—June 25th.—Sewers, &c.—Mr. J. B. Everard, M.I.C.E., 6, Millstone-lane, Leicester.

CHARTHAM DOWNS (NEAR CANTERBURY). — June 30th.—Drainage Works, &c.—Mr. W. J. Jennings, architect, 4, St. Margaret's-street, Canterbury.

QUORN (LEICS.)—Scavenging.—Mr. Geo. White, Rose Cottage, Quorn, Loughborough.

COMPETITIONS.

CASTLETOWN (IRELAND). — June 9th. — Sewerage Works.—The Guardians invite tenders from competent engineers for preparing plans, specifications, and estimates for a scheme of pipe sewerage works for the town of Castletownbere. Sealed tenders, endorsed "Tender for Plans—Sewerage Works," will be received by Mr. M. J. Donovan, executive sanitary officer, Board-room, Workhouse, Castletownbere, up to twelve noon on June 9th.

FORMBY (LANCS), July 1st.—Sewerage Scheme.—The Formby Parochial Committee invite competitive schemes for the sewerage of a portion of the township of Formby. Premiums are offered amounting to £100 for the scheme considered first in order of merit, £50 for the second, and £25 for the third. Mr. J. H. Havelock Sutton, Piercefield-road, Formby. A professional assessor will be appointed to adjudicate upon the plans.

BAILDON (YORKS).—Sewage Purification Scheme.—The Baildon Urban District Council invite plans of a scheme for the purification of the sewage of the Baildon Wood Bottom, Baildon Green, Lower Holme, and Low Mill portions of the Council's district, to be submitted to the Local Government Board for its approval by 30th inst. The successful plans will be paid for, and commission will be paid when the scheme is completed. For further particulars apply to Mr. H. R. Huggins, clerk, Baildon.

To Medical Officers, Surveyors, Sanitary Inspectors, &c.—High-grade Cycles at reasonable prices for prompt cash and on the GRADUAL PAYMENT SYSTEM. Catalogue post free.—MELROSE CYCLE COMPANY, Coventry.

NOTICE.—The Annual Subscription to this Journal has been raised to 12s. 6d. to all NEW Subscribers. NO ADVANCE will be made to our friends whose names were entered on our Subscription list prior to March 31st, so long as they continue to subscribe.

DRUGS

WON'T DO.

FREE TRIAL OF SOMETHING THAT WILL DO.

You would be perfectly astonished if you were made aware of the many thousands of pounds absolutely thrown away from year to year upon so-called curatives that are foisted upon a public only too willing to believe the specious arguments laid before them.

Now, strength and muscular activity, rosy cheeks, plumpness and health, can be obtained without medicine.

It can be accomplished with a perfect, flesh-forming, palatable, and agreeble Food Beverage.

DR TIBBLES' Vi-Cocoa

is such a Food Beverage, possessing, as it does, wonderful nourishing, strengthening, and stimulative powers unsurpassed by any other Food Beverage. Dr. Tibbles' Vi-Cocoa is not a medicine. It does simply what it is claimed to do, and its strengthening powers are being recognised to an extent hitherto unknown in the history of any preparation.

Merit, and merit alone, is what we claim for Dr. Tibbles' Vi-Cocoa, and we are prepared to send to any reader who names this journal (a postcard will do) a dainty sample tin of Dr. Tibbles' Vi-Cocoa free and post paid.

Dr. Tibbles' Vi-Cocoa, 6d., 9d., and 1s. 6d. It can be obtained from all Grocers, Chemists, and Stores, or from Dr. Tibbles' Vi-Cocoa, Limited,, 60, 61, and 62, Bunhill Row, London, E.C.

EXAMINATIONS IN SANITARY SCIENCE.

Examinations for Certificates of Competency in Sanitary Science are held each year as follows, viz.:—In Glasgow in April, in Edinburgh in October, and at such other time and place as the Board of Examiners may determine.

Entrance Fee £2 2s.

For further particulars apply to

GEORGE MIDDLETON, M.A., LL.B.,
Writer, 92, Bath Street, Glasgow,
Secretary to the Board of Examiners.

A Stamped Addressed Envelope must accompany all letters requiring an answer.

SANITARY INSTITUTE EXAMINATIONS.

TUITION BY CORRESPONDENCE.

An Engineer and Surveyor (Mem. San. Inst.), Certificated Surveyor and Inspector, prepares students for these Exams. by Correspondence through the post.

Fees strictly moderate. Cramming studiously avoided.

The course of tuition is arranged so as not only to qualify the student for passing the exams., but what is of equal importance, viz., that he may become a thoroughly efficient Inspector.

On successfully passing the exams., all possible assistance and advice is given to help forward intending candidates for public offices.

Many of my old pupils are now filling positions with salaries of over £120 a year.

For terms, &c., address "C. E.," care SANITARY RECORD, 5. Fetter-lane, London, E.C.

PRACTICAL Smoke Prevention.

By W. NICHOLSON,
Smoke Inspector, Sheffield.

This little booklet, from a practical pen, deals in a comprehensive and capable way with a problem in which most of our big towns and cities are concerned. Its reasonable price should enable it to be distributed wholesale in quarters where the lessons it inculcates would be appreciated, and so distributed, it cannot fail to be productive of much good.

PRESS OPINION.

"A very useful little book, which will be found very instructive to engineers and all having care of steam boilers."—*Liverpool Daily Post.*

The Sanitary Engineer's POCKET REPORT BOOK

For the use of Sanitary Engineers and Sanitary Experts in Examining, Testing, and Reporting on the Drainage, Water Supply, and General Sanitary Condition of Premises.

COMPILED BY

Notes.

A Sad Event.

A GLOOM was cast over the visit of the Association of Municipal and County Engineers to Yorkshire on Saturday last. The Yorkshire centre of this important society had invited a large body of members to its district meeting, and a visit was arranged to the extensive works which the Bradford Corporation have in progress in Nidd Valley for supplying the borough with water. After the members had inspected the Gouthwaite Compensation Reservoir, the company proceeded in a contractors' train along a light railway on the higher slopes of the valley. The train had not gone more than a quarter of a mile when Mr. Tulley, the highly respected Surveyor of Rothwell, near Leeds, fell off the truck on which he was riding. The train was stopped, but on being picked up the unfortunate man was found to be dead. It is believed that the heavy walk over the site of the reservoir caused heart failure. The sad occurrence cast a gloom over the proceedings, and the deepest sympathy was expressed for the deceased man's friends.

Lord Rowton and the London County Council.

How often is it the case that two classes of people wanting to do a good action, but not being able to agree upon some little detail, immediately fly "at one another's throats," and all the good is lost sight of through some imaginary wrong. This is just about what is happening between the London County Council and Lord Rowton's Company. Let us brush away all the legal quibbles, and see if there is really any need for disagreement. Some time ago Lord Rowton conceived the idea of providing a species of "hotel" for the poor man. He had visited the common lodging-house, and he realised how distasteful the customs therein prevailing must be to any one possessing the least sense of refinement or delicacy. Therefore he planned a large house where such might put up, and, above all, where they could enjoy the privacy of a room to themselves—in fact, be exactly the same as if they were putting up at a West End hotel. The house was built, and it "caught on" at once; and similar places have been established in other parts of the metropolis. So far as we can tell, there has never been any ground for complaint proved either against the conduct or the arrangements of Rowton Company's establishments.

"The Letter killeth, the Spirit giveth Life."

BUT the London County Council has its own ideas about the housing of the working classes, and it appears to think that the poor man has no right to the luxury of a "Metropole;" and because the needy, and otherwise homeless, are accommodated, therefore these places must be classed as common lodging-houses, and be subject to inspection by the Council's officers. The claim of the Council has been defeated in the Magistrate's Court, and also in the Divisional Court. Yet we hear a fresh attempt is to be made in the Court of Appeal. We regret such a decision, for it does appear to be a waste of energy and money. Even if it wins, instead of helping the visitors at these hotels—who are striving to assert their individuality and humanity—they will be stamped as part of that seething mass from whom all sense of decency and respectability appears to have departed. Shylock of old was entitled to "a pound of flesh," but in taking that he would have robbed Antonio of his life-blood. So the Council may obtain its desire, and make Lord Rowton's Homes common lodging-houses, but with that the accomplishment of a noble ideal will be thwarted, and the dawn of a returning manhood blotted out to those who are struggling to extricate themselves from the "submerged tenth."

Scarlet Fever at Redditch.

Now and then we come across original modes of procedure in connection with the working of public bodies. In fact, some appear to imagine that whilst it is their duty to administer the various Health Acts, they have a right to invent new conditions and formulate special instructions as to "how the thing is to be done." A case in point comes to hand from Redditch, the seat of the needle industry. It appears that for the past two years, a small epidemic of scarlet fever has been raging in the district. The Notification Act is in force, but there seems to be a difficulty in effecting the isolation of patients, and consequently little or no abatement is perceptible in the extent of the disease. The Medical Officer has over and over again urged the establishment of an isolation hospital, stating in a recent special report that "there was no place where patients could be sent to, and until there were means of isolation he could do nothing. In some houses there were seven or eight children with the fever. There was in some cases only one bedroom, and while this state of things existed he could do nothing in the matter." At last the Council decided to take action; but instead of securing a plot of land and erecting a temporary building, negotiations were entered into with two neighbouring districts to establish a joint hospital.

'Gagging' the M.O.H.

Now, perhaps, there may be strong economical reasons for taking this course—there generally are *before* a joint Board is formed, though they do not always work out quite so well in practice as in theory—but surely a town with 14,000 inhabitants should be able to secure a building at a somewhat less distance than six miles from its borders. However, we suppose the Council deem it the best course to adopt. But now another danger has arisen. It would appear that the Medical Officer is a very rash man, and some of the Council are fearful whether, when the doors of the hospital are opened, that he will at once fill the place with patients. Therefore, a special Committee has been appointed to settle who is to go to the hospital and who is to be kept out. What nonsense! How can a Medical Officer fight disease gagged and bound in this way? And we venture to think the Local Government Board will uphold his action if he ignores the existence of such a Committee. After all, what are to be the grounds for this "discriminating" action on the part of the Committee? All the ratepayers bear the burden of cost, and the rich have as much right to protection as the poor; and if any are excluded through the action of the Council we hope they will have the courage to challenge the legality of such exclusion.

The Aim of Education.

Gradually we are awakening to the fact that it is not sufficient to merely instil the rudiments of the "Three R's" in the minds of boys and girls. True education aims at developing any special capacity a child may possess, or strengthening any of its faculties at present dull or weak. In furtherance of this more modern idea, an interesting lecture was given the other evening by Professor Sully, at one of the summer meetings of the London Society for the Extension of University Teaching. Taking as his topic the "New Methodical Measurement of Children's Capacities," he emphasised the importance of parents and teachers giving, as far as possible, the closest personal observation to the habits of children in their earliest years. One of the most pressing and practical problems to be solved by the teacher was the best way to economise his own time and energy and that of the children by means of a more perfect arrangement of classes. There was a necessity for a different method of classification to the system of jumbling children together, which had hitherto obtained. Common objects, it was found, were more interesting to young children through their use than anything else. For instance, if a child were asked to describe a tree, it would probably say nothing of branches and leaves, but would explain it was a thing to shade one from the sun, or something to climb upon. In methods of play it was strange to see the enormous importance which children attached to ceremony, and in the case of dolls a child made almost a kind of fetish of ceremonial. Many remarkable instances were given of how "dullards" had been trained to become really intelligent scholars by dealing with them individually instead of in the mass.

The Increase of Lunacy.

It seems but yesterday that we recorded the enlargement of Canehill Asylum, and the opening of a new one at Claybury, in Essex. Following closely upon these, it was announced that the London County Council had secured a site near Epsom upon which another was to be erected. In fact, this building is already in progess. Within the last fortnight two others are foreshadowed—one to be built by the Middlesex County Council, and one by the Borough of Croydon. This latter is necessitated by the fact that the agreement with London for housing the lunatics of Croydon expires next June. The site chosen is at Warlingham, Surrey, and will cost close upon £200,000. The increase of lunacy is one of the saddest features of modern life. We may rejoice in the more humane treatment given to those suffering from the "mind diseased," but our joy would be more complete if a "prevention" could be found, for that is better than "cure."

The Bryant and May Prosecution.

The cases of phosphorus poisoning in the match-making factory of Messrs. Bryant and May, Limited, which recently attracted the attention of the Home-office, and have now resulted in the prosecution and conviction of the firm, have a much graver significance than at first appeared. We use the plural advisedly, for though the conviction only related to the case of one person, a woman named Caroline Hawkins, there was no attempt to deny that this was only one of a series of cases that had been deliberately suppressed by the firm. By the special rules relating to lucifer match factories, framed in virtue of the Factory Act of 1891, notice of any symptoms of necrosis or swelling of the jaw must be given to the Medical Officer of Health as certifying surgeon; and the Factory Act of 1895 provides that written notice of every case of phosphorus poisoning shall

be given to the Inspector and to the Certifying Surgeon. Both of these requirements have been systematically contravened by Messrs. Bryant and May. Mr. Vaughan, the Inspector of Factories, stated that the factory had been under inspection for a number of years, and the firm always consistently denied the existence of necrosis in their works. The death of one of their employés, however, led to an inquest, and that to a wider and more searching inquiry, with the result that the firm ultimately made a clean disclosure, and gave up a list of similar cases under treatment by the Medical Officer of the works.

A Grave Offence.

Undoubtedly this was a very grave state of affairs. No attempt was made to deny the charge, and the only attempt at palliation was the statement that only one case had occurred since the framing of the special rules, and that case ended in death before the disease was diagnosed. The presiding magistrate, who was at first disposed to cavil at the laying of summonses under different sections of the Acts, all relating to the duty of notification, with respect to what appeared to be a single case, altered his view after hearing the facts, and characterised the offence as a very serious one, calling for severe treatment and the imposition of the full penalties under each section. We should be disposed to go further, and to say that such conduct on the part of the company indicated the most wanton indifference to the health and safety of their employés, and our only regret is that the penalties could not have been even heavier. There is one aspect of the case that demands some reflection. Mr. Vaughan said that, in consequence of the concealment practised by the firm, the Factory Inspectors had been led to believe that the special rules for the control of the factory and the notification of disease were working satisfactorily; and this compels us to ask the question: How long might such a systematic evasion of the law have continued had not the death of a workman led to a public inquest and an inquiry? And of what avail were the Factory Inspectors when a whole series of cases could thus escape their vigilance? It seems strange that, with our carefully devised code of laws for dealing with factories, it should be possible for employers to so hoodwink the Inspectors as to be able for a considerable time to ignore with impunity the statutory requirements on a matter regarding which the Inspectors should have been particularly on the alert.

The Inequalities of Fines.

We have had occasion more than once recently to remark on the disposition of some magistrates to treat lightly offences against the Food and Drugs Acts by allowing the offenders to escape with nominal fines that could only serve to encourage a repetition of the offences. We had another illustration of the same thing in Edinburgh last week. In two cases—one in which milk was sold deficient to the extent of 16 per cent. in natural fat, and another in which a mixture of coffee and chicory was sold when pure coffee was asked for—convictions were obtained, but the sheriff did not think there was any necessity for the imposition of a fine. It may be admitted that the offences were not of a very serious character still, if the Legislature has deemed it necessary to provide by statute for the checking of such practices, it is the duty of magistrates to carry out the intention of Parliament by enforcing the statutory penalties. By way of contrast with these cases we may observe the heavy penalties imposed in some milk adulteration cases in Glasgow the other day. In one case, where a farmer was convicted of several offences, all of the same character, the sheriff imposed the maximum penalty for each offence, amounting in all to £35. It was a heavy fine, and when we look to the character of the offences, and compare them with the much graver offences in Bryant and May's case, where the accumulated penalties with costs only amounted to £25 9s., we cannot help feeling that it was unnecessarily severe. But the chief thing that strikes one on this question of fines is the great inequality that prevails in different courts, a thing which is much to be regretted. It would be strange, for instance, if the farmer who was mulcted in the fine of £35 for milk adulteration did not smart under a sense of injustice when he read of the very similar case in Edinburgh, where the offender escaped without a fine at all.

The Late Lord Playfair.

In the death of Lord Playfair—more widely known, perhaps, by his old name of Sir Lyon Playfair—a singularly gifted and versatile man has passed from us. At a very early age he made his mark as a chemist of the first rank, for he was barely twenty-four when he received the appointment to the Chair of Chemistry in the Royal Institution of Manchester—that was in 1843—and in subsequent years he filled in rapid succession some of the highest posts the profession could offer him. In 1852 he was appointed Chemist to the Museum of Practical Geology, out of which arose the Royal School of Mines; in 1857 he was elected president of the Chemical Society; and the following year saw his appointment to the Chair of Chemistry in Edinburgh University. Of his parliamentary career and the distinguished posts he occupied in the public service in later years it is impossible for us to speak in this place. It is sufficient merely to allude to his having at various times held the offices of Postmaster-General and Vice-president of the Council, as well as many others of less importance. But Lord Playfair's claim on the remembrance of posterity will chiefly depend on the eminent services he rendered to the union of science and art in our manufactures and industries, to the promotion of which he was able to bring a rare practical knowledge of his favourite science. To take one instance out of many, his report to Government, in conjunction with Sir Henry de la Beche, on the various causes of explosions from gases in mines, was of immense value in suggesting improvements in the direction of preserving the lives of those whose lot is cast in the deep places of the earth. In his capacity of Joint-Secretary of the Science and Art Department he was able still further to promote the same end. But sanitarians will particularly remember with gratitude the services he rendered to the cause of public health. Lord Playfair's death removes the last member of the great Royal Commission on Public Health, which, it is not too much to say, laid the foundation of modern sanitary improvements.

THE CHEMICAL AND BIOLOGICAL ANALYSIS OF WATER.

By T. H. Pearmain and C. G. Moor, M.A.

Members of the Society of Public Analysts. Authors of "Applied Bacteriology;" "The Analysis of Food and Drugs," &c.

(*Continued from page* 586.)

MICROSCOPIC EXAMINATION OF SUSPENDED MATTERS.

CRUSTACEÆ.

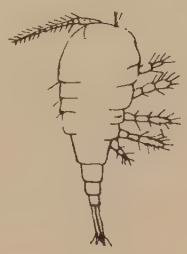
Bosmina longirostris (30).

Cyclops (31).

Daphnia (*water flea*) (32).

30

32



31

All these organisms are characteristic of pond water, and should not be present in a water supply.

INFUSORIA.

It may be said generally of the infusoria that they are characteristic of pond water.

Ceratium (33).—Fairly large infusorian. It is goblet-shaped, and has long projections or spines round the mouth part. The opposite end is drawn out into a spine.

33

34

Coleps (34) is a globular infusorian, looking like a basket, water having access through the meshes or pores of the body. It is covered with cilia, and has an anterior and a posterior opening, both surrounded by short spines.

Euglena (35).—It is a green animal containing chlorophyll, and lives wholly on vegetable foods. It has a long flagellum, at the base of which is a gullet. It has a contractile vacuole, and is actively motile.

35

36

Phasus longicandis (36) is a heart-shaped infusorian. At the anterior end is a single long flagellum. The posterior end is drawn out into a long spine.

Paramœcium bursaria (37).—Commonly called the "slipper animalcule." It is covered with cilia, and has a flattened form. The mouth is on the ventral side, a little to one side, and leads into a gullet. It has a layer of trichocysts below the ectoplasm (skin). These are pointed rods, which it ejects when irritated. It has two nuclei.

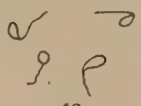
37

38

Polytoma (38).—It is the simplest of the infusoria. It is saphrophytic, and takes its food in solution, living in putrefying animal or vegetable matter. It has no mouth, and absorbs its food by the osmotic power of the body substance. It has two flagella, and there is a delicate invisible cuticle bounding the body.

Paramonas globosa (39).—Very small, heart-shaped, with one flagellum.

39



40

Pleuromonas jaculans (40).—Small pear-shaped organisms with one flagellum.

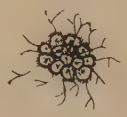
Stentor (41) is trumpet-shaped, and fixed by the narrow end. Body is uniformly covered with cilia, and at the front end of the body is a spiral layer of longer cilia.

41

42

Stylonichia (42).—It is shaped something like paramœcium. It has a strong layer of cilia round the mouth. The dorsal surface has no cilia, but has stiff hairs, which are really immovable cilia.

Synura uvella (43).—Forms round, irregular clups. Each individual is round and ciliated, and has one long bifid flagellum.



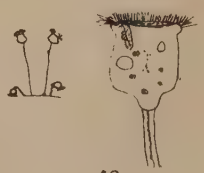
43

44

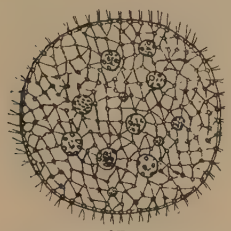
45

Trachelomonas cylindrica (44), *piscatoris* (45).—These organisms are bottle-shaped. At the anterior end is a single large flagellum set in a collar.

Vorticella (46).—This organism is cup-shaped, and is attached to the substratum by a long contractile stalk. The body has a lid, and both the lid and the opening into the gullet are strongly ciliated. The nucleus is horseshoe shaped.



46



47

Volvox globator (47).—Green, globular colony of individuals. The colony is spherical, and the individual creatures live in the wall of the sphere. Each has two flagella, a nucleus, and is green. The ball, or hollow colony, continually rotates by means of the flagella of each individual. This organism gives rise to a fishy taste and smell in water.

INSECTA.

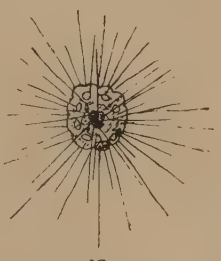
Tardigrada.—Commonly known as the "water bear." It has four legs, which end in stiff cilia, which help it to hold on to water plants. The head has no antennæ, and has eyes; the mouth is suctional. It is microscopic in size, and is found in pond water.

PORIFERA.

Spongilla fluviatilis.—The only fresh-water sponge. It grows in greenish masses in canals and fresh-water lakes. The sponge itself is an inch or more in diameter; the spicules are most likely to be noticed.

PROTOZOA.

Actinophrys sol (48).—This is a small round animalcule with one nucleus. It is surrounded by stiff, radiating pseudopodia. Found in pond water.



43

49

Amœba (49).—One of the simplest animals. It consists of a shapeless mass of protoplasm, which is constantly flowing out into blunt, uneven, lobose prolongations—the pseudopodia. It has no mouth, and the food is taken right into the protoplasm and digested, and the undigested part thrown out again.

Difflugia (50).—This organism has a coating formed by sand which it has taken into its body, and with which it makes a globular shell, inside of which is the soft protoplasm of the body substance. This flows out at the mouth of the shell and forms anastomosing threads, which catch the food of the animal, acting as a net.

50

51

Arcella (51).—This organism has a shell which partly covers it. On the flat ventral side is an aperture, through which the naked protoplasm exudes as lobose pseudopodia. In the body substance are seen vacuoles containing gas. These are hydrostatic in function.

ROTIFERÆ.

The rotiferæ generally are characteristic of stagnant water full of organic matter.

Anurea cochlearis (52).
Polyarthra platyptera (53).

52

53

54

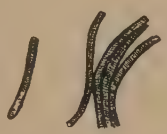
Rotifer vulgaris (54).—The first to be discovered. Gives a red or green colour to gutter water. It is often called the "wheel" animalcule, on account of a circular, oral disc, which is fringed with cilia, which is motile, and by its movements conveys an appearance of rotation, and serves to propel the animal and to set up food currents.

VERMES.

Anguillula fluviatilis (55).—Characteristic of dirty water.

55

PARASITES AFFECTING MAN.

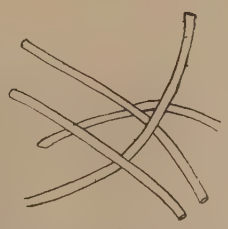


56

In addition to the various animal and vegetable organisms mentioned above polluted waters may contain undigested muscular fibres (56) or epithelial scales, or the various fibres of clothing—linen (57), wool (58), silk (59), and cotton (60).

57

58



59

60

In this country the eggs of the following para-

sites might be found in water:—Ascaris lumbricoides (or round worm), bothriocephalus latus, oxyuris vermicularis (thread worm), tænia mediocanellata, and tænia solium.

The ova of certain parasites which occur abroad are known to be conveyed by water, and while this may be the case with some of those common to this country, there does not appear to be any reliable information on the point.

(To be continued.)

LIME, MORTAR, AND CEMENT: THEIR COMPOSITION AND ANALYSES.

By W. J. DIBDIN, F.I.C., F.C.S,, &c.

(*Continued from page* 560.)

CHAPTER V.

TYPICAL ANALYSES OF MORTAR AND CEMENT.

During the past twenty years I have had many opportunities of analysing various samples of cement and mortar, and of the sand which has been adopted as a standard for use in testing the strength of cement—having been associated with the late Mr. John Grant, formerly engineer in charge of the southern district of London during the building of the main drainage scheme under the late Metropolitan Board of Works, and whose work on cement has for long been the standard of reference in regard to the mechanical tests, &c. From my results obtained in the course of this work, I have selected the following series of typical analyses from my note-book, and have added thereto the results of analyses of mortar which were first published in a paper read before the Society of Public Analysts by myself and Mr. R. Grimwood, F.I.C., &c., in 1896. As the value of this paper is greatly enhanced by the discussion thereon, I venture to print the whole *in extenso*, merely reserving that portion devoted to analytical methods for a later chapter, in which they will be more fully dealt with. Together, these analyses form a sequence which will be of interest and value to those who are desirous of ascertaining the character of samples which have been submitted to analysis, as by comparing the results found with the following they will be able to assign to the sample its proper position in the scale of quality. Thus it may be a mixture of good materials, or adulterated, or one, though honestly made up by the workman, has yet been mixed with poor materials. It is not intended to be conveyed, however, that the mere analysis of a particular sample will indicate the setting power of a cement. This, it will be at once seen on consideration, must be affected more or less, if not entirely, by the physical character of the cement, especially in regard to the manner of its burning, grinding, &c. A cement may contain all the ingredients of a first-class cement, but if it is not properly prepared it will be useless; just as a cook may throw together all the ingredients of a Christmas pudding, but if it is spoilt in the cooking, the result is a failure.

THE LEGAL SPECIFICATION OF MORTAR.

In the bye-laws made by the London County Council, under Section 16 of the Metropolitan Management and Building Acts Amendment Act, 1878, it is provided that the mortar used under that Act must be composed of freshly-burnt lime and clean sharp sand or grit, without earthy matter, in the proportions of one of lime to three of sand or grit.

In the case of cement-mortar, the cement to be used must be Portland cement, or other cement of equal quality to be approved by the district surveyor, mixed with clean sharp sand or grit, in the proportions of one of cement to four of sand or grit; also that burnt ballast or broken brick may be substituted for sand or grit, provided such material be properly mixed with lime in a mortar mill.

In the bye-laws made by the Council under Section 31 of the London County Council (General Powers) Act, 1890, it is provided that plastering or coarse stuff shall be composed of lime and sand, in the proportion of one of lime to three of sand, mixed with water and hair; but Portland, Keene's Parian, Selenitic, or other cement or plaster of Paris, may also be used for plastering. The lime must be freshly-burnt lime; the sand must be clean sharp sand, free from loam or earthy matter; the hair must be good and sound, free from grease or dirt, and one pound of hair be used to every three cubic feet of coarse stuff. Fibrous material may be used instead of hair, and ground brick or furnace slag, each to the satisfaction of the district surveyor, may be used instead of sand; and the setting coat must be composed of lime or cement mixed with clean washed sand, or cement only.

USUAL CHARACTER OF MORTARS.

Earthy Matter.—From these extracts from the bye-laws relating to the use of building materials in the metropolis, it will be seen that an analysis of lime mortar or cement mortar, &c., can be conducted with a degree of accuracy sufficient to indicate very slight departures from the prescribed quantities of the materials used. Unfortunately analyses which have been made from time to time by us (Dibdin and Grimwood) have shown distinctly that it is only under exceptional circumstances that mortars which come within these regulations are employed. To take one factor only, the earthy matter: analysis of samples of mortar, made with materials selected as coming within the definition of the bye-laws, and in the proportions therein set out, shows that the earthy matter, as determined by us in the manner described hereafter, varied as follows:—1·5, 2·1, 0·14, 0·74, 0·81, 0·61, 0·64, 0·96, 0·85, and 0·70 per cent.; thus showing that the finely-divided matters which may be accidentally introduced by means of the broken brick or sand form but a very small proportion of the actual weight of the mortar. As compared with these, the following results obtained from the examination of a number of samples of mortars taken from a building in course of erection will indicate the great difference in this respect, viz., 4·9, 3·8, 9·1, 3·4, 14·7, 13·7, 7·4, 10·4, 8·1, 12·3, per cent.

Soluble Silica.—Another factor of importance in estimating approximately the quantity of cement in a genuine cement mortar is that of the soluble silica. As is well known, the silica, soluble in hydrochloric acid, present in Portland cement will vary between 17 and 20 per cent.; but if the average is taken at about 18 per cent., it will form a fair basis for calculation.

If the cement-mortar is made with good Portland cement, and clean well-burnt brick or sand in the proportion of one of cement to four of the grit, there will be about 3½ per cent. of soluble silica. In some samples of genuine cement mortar, the soluble silica was found to be 3·25, 2·5, 3·25, and 2·25 per cent.; as against these samples of genuine mortar made with lime gave soluble silica equal to 0·9, 1·0, 0·6 traces, and 1·1. If we now turn to the analyses of commercial mortars (see Table V.) above referred to, we find that the soluble silica varied as follows: 0·9, 0·7, 0·7; thus showing a very marked difference between this factor under different circumstances.

Carbonic Acid.—A third factor is the quantity of carbonic acid. Genuine mortars made with good materials were found to contain, after the mortar had been made for some three months, carbonic acid equal to 1·02, 1·36, and 1·06 per cent. of carbonate of lime; and the cement-mortars to contain carbonic acid equal to 2·86, 2·86, 1·04, 1·87, 1·45 per cent. of carbonate of lime. Freshly-prepared mortar made with good materials contained in two instances 0·3 and 0·4 per cent. carbonate of lime. Against these, the commercial mortars contained 6·42, 6·24, 7·39, 4·52, 8·9, 8·4, 8·0, and 4·5 per cent.; thus showing conclusively that this factor alone gave such marked indications of the character of the material that it would be almost impossible that a mistake should be made in estimating the character of a given sample of mortar or cement. It is to be noted that certain bricks contain carbonate of lime, and this should be determined before concluding that the mortar is made with old materials or insufficiently burnt limestone. In Table I. an instance is given of a brick containing 7·77 per cent. of carbonate of lime. The full details of these analyses are given in the tables at the end of the chapter.

TABLE I.

Sample of the Lime used in making Mortar.

	Per cent.
Lime (CaO)	78·40
„ carbonate	3·22
„ sulphate	0·64
Soluble silica, iron oxide, and alumina	12·85
Sand	4·80
Total	99·91

Sample of the Brick used in making Mortar.

	Per cent.
Moisture (loss at 212 deg. Fah.)	1·27
Lime (CaO)	1·99
„ carbonate	7·77
„ sulphate	1·03
Soluble silica, iron oxide, and alumina	3·60
Insoluble matter—crushed brick	78·77
Insoluble matter—fine (this had the appearance of having been burnt)	1·69
Total	96·12

Relation of Weight to Volume (Lime Mortar.)—In the bye-laws of the London County Council it is provided that the quantities are to be by volume, and not by weight; therefore the analysis, being stated by weight, must be converted into terms of volume. In order to show how this is arrived at, the following comparative analysis of a sample of mortar made with broken brick, specially prepared for this purpose, will make the point clear. The analyses of the lime and broken brick are given in Table I., and in Table II. that of the mortar made with one volume of lime and three volumes of brick. In this case the brick had some old mortar adhering to it, as would happen where old bricks are used.

TABLE II.

Sample of Mortar made with One Part by Measure of Lime and Three Parts Crushed Brick.

	Per cent.
Moisture, water of hydration, &c.	29·71
Lime (CaO) (= 16·06 commercial lime.)	12·85
Lime, carbonate	4·47
„ sulphate	0·61
Crushed brick	46·03
Iron oxide and alumina	2·80
Soluble silica	1·85
Earthy matter (this had the appearance of having been burnt)	0·70
Loss on ignition	0·98
Total	100·00

Commercial lime (containing 80 per cent. of CaO) to crushed brick, 1 to 2·29 by volume; to all other matters, 1 to 2·86 by volume.

In this it will be seen that the earthy matter was 0·70 per cent. in the mortar, and the lime (as pure lime) 12·85 per cent., equal to 16·06 per cent. commercial lime of 80 per cent. pure CaO.

The brick (Table I.), as already mentioned, contained 7·77 per cent. of carbonate of lime. Another instance is given in Table III. of the analyses of lime and mortar made therewith and good brick. In this the carbonate of lime was only 1·97 per cent. on the mortar.

TABLE III.

Analyses of Stone-lime and Mortar made therefrom.

	Stone lime.	Mortar. Lime 1: brick 3 parts by volume.
Moisture, water of hydration, and loss	1·86	31·23
Lime (CaO)	78·63	10·89
Carb. lime	0·93	1·97
Sulphate of lime	None	0·61
Iron oxide and alumina	4·30	3·55
Soluble silica	7·10	1·11
Sand and grit	Trace	45·99
Earthy matter	6·20	1·37
Loss on ignition	0·98	3·28
	100·00	100·00

A large number of experiments on different samples of ground-up brick and various samples of lime, &c., have shown that it is a safe guide, in determining the volume of the materials from their weight, to increase the weight of lime found in the analysis by one-fourth in order to raise the lime (CaO) obtained to the relative quantity of *commercial* lime, on the assumption that the commercial lime originally contained 80 per cent. of pure oxide of calcium. The correction from weight to volume is then made by again increasing the weight by one-fourth.

The following will illustrate the method:—
Equal volumes of stone-lime and of air-dry broken brick weighed as follows:—

Lime	...	...	17·38 grammes per 18·5 c.c.
Brick	...	...	21·13 „ „

(1) To convert weight of commercial lime to equal volume of broken brick, add one quarter of the weight of lime found to itself, thus: 17·38 + 4·34 = 21·72.

(2) By analysis this lime contained 78·63 per cent. of real CaO, and a mortar made with this lime on analysis gave 10·89 per cent. of CaO; therefore, to convert CaO in mortar into terms of commercial lime, for practical purposes add one quarter of the weight of CaO found in that quantity. Thus, CaO in mortar 10·89 per cent. + 2·72 = 13·61 commercial lime.

(3) By No. 1, 13·61 + 3·4 = 17·0 of CaO by volume.

(4) The ground brick used in making the mortar (Table III.) contained 6 per cent. of matters soluble in weak acid; therefore, to the weight of brick-grit actually found add 6 per cent., *i.e.*, sand and grit (brick). 45·99 (45·99 × 0·06 = 2·76) = 48·75.

(5) Lime to brick by volume: 17 : 49, or 1 : 3 nearly.

RELATION OF WEIGHT TO VOLUME (CEMENT-MORTAR).

Equal volumes of washed and dried sand and of Portland cement of specific gravity 3·15 weighed 21·7 grammes and 19·3 grammes respectively. Therefore the weight of cement found must be raised by one-eighth to obtain a factor which shall equal the sand in terms of volume.

Average Portland cement will contain from 17 to 20 per cent. of soluble silica. An average of 18 per cent. may therefore be taken, on which assumption the soluble silica formed may be calculated into terms of cement. Thus, the 3·25 per cent. of soluble silica found in sample No. 1, Table IV., would equal 18 per cent., or 19·25 per cent. corrected for volume. The sand and grit equalled 67·34 per cent.; therefore the ratio of cement to sand was 1 : 3·5. In sample No. 2 of the same table the soluble silica was 2·5 = 13·9 per cent. of cement = 15·6 by volume; the sand, &c., was 70·77 per cent.; the ratio consequently was 1 : 4·5. Sample No. 3 showed a ratio of 1 : 3·5, No. 4 of 1 : 5·6, and No. 5 of 1 : 4·8, the average being 1 : 4·4. The samples were stated to be from cement-mortars, made with 1 of cement to 4 of sand. Doubtless the difference is due to unequal mixing.

ABSORPTION OF CO_2 AFTER MORTAR IS MADE.

The crushed brick (see Table I.) including some of the silica, iron oxide, and alumina, would amount to 48 per cent., or 51·77 per cent., including 3·74 per cent. of carbonate of lime found on analysis to be present in the brick. The commercial lime used contained 3·22 per cent. of carbonate of lime, so that the above 16·06 per cent. would contain 0·52 per cent. These together will account for 4·26 per cent. of the carbonate of lime in the quantity found in the above analysis, showing that only 0·21 per cent. of carbonate of lime was formed between the times when the mortar was made and analysed.

(To be continued).

SANITATION OF COUNTRY HOUSES, VILLAGES, AND SMALL AREAS.*

By EDWARD TIDMAN, C.E., F.S.I.

THE author consented at the request of the branch chairman, Mr. Branson, to read a paper at one of the branch meetings, and, in doing so, thought that a paper treating the above subject would probably be acceptable from the Surveyor's point of view, many members of the branch holding dual appointments as Surveyors and Sanitary Inspectors, and to leave the Chairman of Council to deal with a subject more interesting from a Sanitary Inspector's point of view; trusting to the kind indulgence of the members if he travels over ground that to many must be somewhat hackneyed.

With regard to the "internal" fittings of the house, little need here be said, there being no appreciable difference in these arrangements, whether the house be in the country or in a town. The remarks thereon will therefore be limited to a description of the general principles to be adopted in either case, and may be shortly described as follows:—

As far as possible, the drainage should be kept outside the house, and should be constructed of salt glazed sanitary or cast iron pipes. The drains should be laid on 6in. of Portland cement, and, if constructed of stoneware pipes, be also encased IN 6in. of cement concrete, the author's rule being that the excavation shall be 7in. below the level of invert of drain pipe, and the drain 20in. wide for 6in., and 18in. for 4in. pipes. When cast iron pipes are used there is less fear of fracture, and the precaution of a concrete case may be dispensed with. Great care should be used to remove any cement that may have escaped into the inside of pipes in laying; the best remedy for this is to use the Hassall's patent single joint, which prevents the possibility of any cement escaping within the pipe, and allows of a good cement joint outside.

The dimension of the drains should be, for mains 6in., with 4in. branches, and, when complete, should stand a hydraulic test, according to circumstances, of 5ft. to 15ft.; falls should not be less than 1 in 50, unless some means is used for periodical flushing. There should be access chambers at all important parts, and it is better to have too many rather than too few. The outfall, whether into a cesspool, sewer, long outfall, drain, irrigation outfall, or what not, should be fitted with an accessible interceptor trap of a modern type, and from the house side of this accessible trap there should be a vertical ventilating pipe at or about the ground level, fitted with an iron non-return valve or not, according to circumstances. The outlet being formed by the soil pipe or independent vent pipe at or near the highest point of the drain with such additional vents, inlet or outlet, as may be necessary to secure circulation through the entire house drain and also the branches above, say, 6ft. from any "circulating" drain.

The soil pipe branches should pass directly from the trap of closet into the drain or soil pipe outside, and the soil pipe should have few or no bends or

* Paper read at the Northamptonshire and Adjoining Counties Branch of the Sanitary Inspectors' Association, at Northampton Town Hall, May 21st, 1898.

any obstruction to prevent the free flow of air, and should not be more than 4in. or less than 3½in. diameter, and where there is more than one closet or a soil pipe care should be taken to provide the necessary anti-syphonage or bye-passes to prevent syphonage of traps or gullies. All rain-water pipes, whether delivering into sewage drain or not, should be fitted with gullies and cast iron grids, the inlet being under the grid. The waste pipes from sinks, baths, lavatories, &c., should be trapped, and discharge either into channels leading to open gullies or into vertical pipe heads. Cistern overflows and safe wastes should have their discharges direct into open air. Closets should be next external walls, have ample light and air, even at the sacrifice of what may appear on the plan to be a more important matter. With regard to closets, sinks, and other internal fittings, these may be left very much to the taste of the occupier, with the exception that no "pan," "circular flush," or "wash-out" closet should be allowed under any circumstances. The author's practice is to have pedestal "wash-down" closets for servants and ground-floor closets, and either a "valve" or "wash-down" with full seat for most upper floors; only using such closet as permits access to the joints.

These essential points having been described, the elaboration of detail, the cost of fittings, the material and other matters of taste may be left to the individual concerned, to settle as he desires. When these points are noted, at the commencement of a building, the expense of a sanitary system so fitted is little in excess of the old and happily almost obsolete systems in vogue in the early part of the century. A word may here be said as to the systems of drainage and soil pipes, and they may shortly be described as three:—(1) The old system without interceptor and ventilator; (2) the system of little or no ventilation to underground drains, with buried traps at foot, but from which the soil pipe is cut off from direct connection with drain, and which is known as "Norman Shaw's System;" and (3) the system of interception and through circulation, as described in the essential conditions for perfect sanitation.

With regard to the first, this plan is practically now extinct in new houses, and little may be said of it beyond "that wherever it is found to exist in old houses the sooner it is altered and removed the better," and that it never should be fitted to any new house under any circumstances. With regard to the second, or "Norman Shaw" system, this seems to have developed from the difficulties found to exist in providing a suitable line for soil and vent pipes in erecting mansions of a certain style of architecture favoured by this architect and his contemporaries, and from the difficulty often found in improving existing houses fitted on the first-named system, without fixing what some people consider unsightly vent pipes; and this was done by putting in a buried P or S trap at the end of the drain formed into a trumpet mouth with brickwork and cement, into which the soil pipe delivers with open end. The soil pipe being cut off by an open head on the floor level into which the closet outgo delivers, by this means the soil pipe is open at both ends, and is ventilated without any so-called "unsightly" (?) vent pipes running up to the top of the building. There are modifications of this system by Buchan and others, but these are its salient points. With regard to the third, I need add little. It possesses all the good points of the others and none of the bad—except, maybe, the sentimental one of the unsightly vent pipe.

And now, having wearied you with a reiteration of much that you are fully conversant with, we will come to the outfall. In most rural dwellings there is a cesspool at the outfall, and when this exists, or is contemplated, too much care cannot be exercised in the choice of a site and in its construction.

CESSPOOL REGULATIONS UNDER THE MODEL BYE-LAWS OF THE L.G.B.

These regulations are exceedingly well suited to all cases of cesspool drainage, and should form the basis, with but slight modifications, of any specification where cesspool drainage is a necessity. The ventilation of the cesspool is the least clearly described, and it is to this that attention should be drawn. The author's experience has been that in cesspool ventilation the vent drain is invariably taken to the foot of a tree; when the pipe is very much "up a tree" as a ventilator, it is frequently of zinc or of cast iron, with a cement joint to sanitary pipe, and this, through the vibration and the movement of the tree in a gale, is broken off, with the result that the vent is, after all, on the surface. These vents the author always removes, and substitutes a cast iron column, fixed in a concrete base; thus fixed, it is not subject to the same wind pressure, and with its outlet ten, twelve, or fifteen feet from the ground-line, is always in good order and efficient, which the previously described system is not.

In some cases, the whole of the sewage and rainfall is conveyed by one drain outfall, in other cases, the "separate" system is adopted, by which the storm, rain, and subsoil is drained into tanks for domestic or garden purposes, and the fæces, urine, and slops is conveyed to the cesspool; the advantages of the separate system are that it avoids excessive dilution, and lessens the volume of sewage water to treat at the outfall.

Sewage must not (under the provision of the Rivers Pollution Act) flow into rivers, even from isolated dwellings in country places, or into canals, ponds, or lakes, until it has been purified from all noxious and foul matter by the "best practical and available means;" the amount of impurity allowable being not more than as described in the following table per 100,000 parts:—

Organic nitrogen ...	0·3	Dissolved matters.
Organic carbon ...	2·0	
Metallic arsenic ...	0·05	
Mineral	3·00	Suspended matters.
Organic	1·0	

The objections to treatment by subsidiary and precipitating tanks and methods are that, with few exceptions, they do not purify, they only "clarify," and depend for their working on employés, and hence little dependence can be placed on the regular and efficient working; even without considering the expense of chemicals, a tank is little more than a large cesspool, and without some of its advantages.

One system is to apply the sewage direct to the land by intermittent downward filtration, avoiding clay land as much as possible for the purpose. By this system, on suitable land, the sewage of 3000 persons may be successfully treated on one acre, but as the land must have rest alternately for two years, three acres should be provided, and will return

good crops of grass and vegetables. This system is adopted for the sewage of about one-fourth of the population of Paris, and on the author's visit to the sewage farm and gardens at Genevilliers, in 1892, he found excellent crops of fruit and flowers being grown without the slightest ill-effects to the district or unpleasant odours, the effluent passing off pure, sweet, and harmless into the Seine.

"Wide surface irrigation" is another system, this requiring about one acre per 100 persons. Whichever plan is adopted it should be placed at some distance from the dwellings, so as to avoid any idea of a nuisance, although, if well arranged and attended to, none will in reality exist.

There is a system of "sub-irrigation," which is very efficient in some soils. By this system the sewage is distributed to the land below the surface by pipes, those frequently used being 3in. field pipes with open joints, laid near the surface on a bed of porous material. The sewage flows out at the joints and percolates through the earth; when the land is close and of a clayey nature there are disadvantages in this, as it renders the earth cold and sodden, and should be arranged to work in sections. Where sewage is treated on the surface by wide surface irrigation, the site chosen should not be too flat or too steep, and should be laid in slopes; free soils require a gradient of 1 in 20 to 25 or less, dependent, of course, on the nature of the soil. There should be conduits from the cesspool or outfall drain. This may be covered or not, according to their position, and should deliver into distributing carriers, also uncovered. These carriers require outlets fitted with stops, irrigation outlets, or penstocks, to direct the flow and supply all parts of the soil evenly.

The "catch water" carriers follow the contour lines of the land, one under the other, with fall enough just to carry the sewage forward and distribute it over the land by the help of the "stops" and flows over several, being probably not entirely absorbed and purified when it at last leaves the land. This plan is the best when rye grass is grown. The pane-and-gutter plan is to divide the ground into wide beds, with but little fall, and is fed with gutters on the highest part. This requires the land carefully levelled to prevent sludge pools collecting and creating a nuisance. A third plan is to lay out the land in ridges and furrows in parallel straight lines, with carriers or gutters on the ridges, and stop to let out the sewage. These beds should be 30ft. to 100ft., and the slope 1 in 25 to 1 in 100. But probably the best is that used at Genevilliers, where the land is laid out for the sewage to pass down furrows between narrow ridges formed by a double-mould board plough, the space between being just wide enough for the rows of plants; when the crops are removed the rows are again split, and the land levelled for other crops.

Where irrigation in any form is impracticable, or only so to a limited extent, "precipitation" becomes a necessity, therefore some description of the various processes may be useful.

The chief methods in use are:—

(1) The lime process.—This is applied by using, say, twelve grains to the gallon, stirring and settling; the solid matters are left in the water, and the ammonia is lost.

(2) A B C.—Another process is known as the A B C, and is used in some large towns, but is not suitable for the purposes treated upon in this paper.

(3) Phosphate of aluminium and calcium.—These are added to the sewage, which curdles and coagulates the fæcal matter, and after settling in tanks the clear water is allowed to flow off, and the solids are dried; it is, however, not fit for rivers, yet is allowed to run into the Lee, in Hertfordshire, above the intakes of the London Water Company.

(4) Sulphates of aluminium.—This process is used at Coventry, and is a mixture of clay and sulphuric acid, 1 lb. to the 100 gallons, with common lime added; the water is then used over land cropped with rye grass and oziers.

(5) "Scott's" process is a lime and clay process, whereby the solids are precipitated and then dried and burnt, and made into Portland cement.

(6) "Webster's" method is to treat the sewage by electricity. Gases are formed which carry the solids to the top, the liquid is agitated, the gases set free, and the solids settle, and will not again diffuse through the liquid.

(7) A process which has claimed some attention is that known as the "International" process, and certainly has met with considerable success. The process is (*a*) to precipitate and deodorise the sewage in settling tanks by the aid of a magnetic precipitant and deodorant called "Ferrozone;" (*b*) to pass the partly-purified sewage effluent from the settling tanks through "Polarite" filter beds, which arrest any solids remaining in suspension, and oxidise and render innocuous the putrescible matter held in solution. Ferrozone is the trade name of a material, rich in salts of iron, alumina, and magnesia, and contains magnetic oxide of iron in a spongy and absorbent condition, which deodorises and disinfects the sewage, and causes subsidence of the suspended solids. Polarite is also a trade name for a material for filtering and further purifying the ferrozoned sewage from putrescible dissolved matter. It is black, hard, porous, magnetic, insoluble, and practically everlasting. The cost is given as one farthing per 1000 gallons treated for ferrozone and for polarite, the interest and working expense only on the cost of the filters, which for a mansion would represent a capital outlay of about £100.

THE HYGIENE OF CLOTHING.

IT is probable that man was originally a tropical animal, perfectly adapted to his environment in a physical point of view, the natural product of evolution under the conditions in which he lived. Since he has emerged from his primal state and extended his habitat throughout nearly all latitudes and climates and has become a garment-wearing animal a host of unnatural and insanitary possibilities has arisen. The question of clothing, what to wear and how to wear it, has an importance altogether aside from the social and æsthetic, and even from some of the ordinarily recognised considerations of comfort that commonly govern our selection. The hygienic choice of clothing, when it is not interfered with by conventional or economic or other factors, is usually a rule-of-thumb procedure, that takes little or no account of the chances or consequences of error. This is more especially true in our so-called temperate climates, where every extreme of temperature is experienced, often within the compass of a few days or weeks, or in some localities even a day. The result is a sacrifice

of human comfort, health, and even of human life, that is none the less formidable and real because it is unappreciated even by the victims themselves. The average layman's idea of hygiene is ordinarily that it is a matter that concerns diet, water supply, drainage, &c., and the subject of clothing is one of the very last that occurs to him under this head. The relative importance attributed to these other matters by sanitarians encourages this error, and it may be asked whether we are not guilty of forgetting or condoning some of the commoner sins against good health in this regard; our familiarity with them has led to their neglect. We change our summer and winter costumes, for example, according to the calendar or our individual whims and feelings, and the result is often a crop of lung and bronchial affections and the aggravation of those already existing. According to Rubner, the most recent writer who has treated the subject systematically, the average man is, as a rule, too warmly clothed in summer, and this, even with good ventilation, is an evil that should be avoided, and tends to increased perspiration and abnormal activity of the skin, which in many ways may lead to evil consequences. With ill-ventilated clothing confining the perspiration and its excretions, we have a condition that interprets itself, often to our unaided senses, as hardly more compatible in principle with perfect sanitation than is an undrained cellar sending its exhalations into the living-rooms above. The necessary removal of clothing at least once a day relieves matters somewhat, but the betterment is only in degree, not in kind, and is at best only temporary if the same undergarments are resumed the following day. The problem of a proper and thoroughly healthful and comfortable summer costume in our climate adapted to all the exigencies of weather and occupation is certainly a complex one, and it is perhaps too much to expect that it can be perfectly solved. The best we can look for, perhaps, is to reduce the possible evils to a minimum, not to abolish them.

The question of winter clothing is, according to Rubner, a simple one, the chief demand is for sufficient warmth; the excretory function of the skin is not so actively in evidence, and the difference of external and bodily temperature in itself is sufficient to effect or materially aid in such ventilation as is required. The external conditions themselves more directly indicate the needs than is the case in summer, and errors are less likely to be made.

It is in a variable climate such as ours that the hygiene of clothing needs most particular attention, and more especially in the changeable weather of the transitions from winter to summer and summer to winter. In the tropics one readily learns how to adapt himself to his surroundings, and as a rule the white race in those regions does not attempt occupations that are unsuited to his conventional costume, at least for any length of time. In the arctic regions, also, the clothing is rationally adapted to the climate, and the freedom from colds and lung disease experienced there is not altogether due to the absence of germs. It is in the middle latitudes, in temperate regions, with their wide ranges of temperature and changing seasons, that the choice of clothing becomes a serious sanitary problem too often neglected, but none the less important and worthy of earnest attention. The public is at present left too largely to its own devices as regards this matter, and while the result is not altogether as bad as it might be, it is certainly not an ideal one in a sanitary point of view.

BACTERIOLOGICAL v. CHEMICAL EXAMINATION OF WATER.

Dr. Dunham, in a paper read before the American Chemical Society last spring, stated the case thusly: "The chief aim of an examination of water with reference to its fitness for drinking is to learn whether it contains, or is likely in the future to contain, poisonous substances or the contagion of disease. The detection of mineral poison falls within the domain of chemistry. The actual isolation of specific bacteria of disease can only be done by bacteriological methods." This is perfectly true so far as it goes, but he has only stated part of the case of the chemist, and the smaller part at that.

Leaving out of the question the possible extent to which bacteriological examination may be pushed, the practical and usual examination consists of counting the number of bacteria per cubic centimetre, and searching for the typhoid bacillus and the bacillus coli communis. The latter, as a constant quantity in fæces, indicates sewage pollution. The typhoid bacillus is rarely found in drinking water, although almost positively known to be present. This leaves the colon bacillus as the main evidence of the bacteriologist of sewage contamination, and as he does not find the pathogenic germ he cannot do more than class the water as dangerous.

The chemist has very little to do with the mineral poisons in water before referred to, and finds them less often perhaps than the typhoid bacillus is found, but in the majority of cases can detect sewage pollution more certainly than the coli bacillus will indicate it, and he says the water is dangerous.

It should be remembered that the bacteriologist looks for something that is in suspension, while the chemist determines substances in solution. The bacillus may, in the case of well water, be temporarily filtered, while the soluble matters are not affected. On the other hand, the polluting matter may be so largely diluted that chemical tests will fail to reveal it, and yet there may be enough coli bacillus to give a positive indication.

MODERN SANITATION AND THE ANCIENT HINDOO RELIGION.

On March 25th Surgeon-Lieutenant-Colonel W. G. King delivered at Madras University a long and able address to the newly-admitted graduates in law, medicine, engineering, and arts. After appropriate exhortations to the members of each of the several faculties he urged the graduates as a body to remember that it was to them as educated fellow-countrymen that the people looked for guidance in the midst of doubts and perplexities as to whether Western civilisation was not incompatible with native religious opinions and customs. For instance, the advance of sanitary reform is almost entirely dependent upon the ability of the better-informed classes to influence the uneducated populace. "Those of you who have studied the learned shastras of your forefathers," he said,

"must have found ample room for opinion that not only is modern sanitation compatible with caste, but that caste itself, although allied with religious observances, is a magnificent and elaborate system of sanitation."

"But in the absence of the knowledge of Sanskrit in which these rules were conveyed, tradition, which has been the method of transmission from generation to generation, has led to no little distortion of the original dicta." For instance, the laws of Manu teem with minute directions as to the collection, retention, and withdrawal of water in a pure state, but unfortunately the perversion of the sense of the original shastras has led to wholesale pollution of rivers. In seeking to provide a public water-supply free from any form of animal contamination, the various Local Authorities do not introduce any innovation contrary to caste requirements, and act in strict accordance with the spirit of the shastras, and the same may be said with respect to the measures of segregation and disinfection during the present prevalence of plague, which, however, have been resisted on the assumption that they were inimical to caste. In fact, if there has been anything taught by caste, it is the necessity for segregation as an aid against the spread of disease, the conditions which determine the duration and nature of the segregation being clearly shown by the laws of Manu and the edicts of Vishnu. On this occasion, for the first time in Madras University, an Indian lady obtained a degree in arts.

RICHMOND AND ISLEWORTH ISOLATION HOSPITAL.

LAST week the Duke of Cambridge formally opened the new isolation hospital which has been erected between Isleworth and Twickenham by the joint Board of Richmond, Heston, and Isleworth. The buildings are almost hidden from the London-road amongst the orchard trees midway between Twickenham and Isleworth village, with Kneller Hall, the Royal Military School of Music, not far away to the north-west. The block of buildings, which has been erected by Messrs. J. Godson and Sons, of Kilburn, at a cost of £13,598, is from the design of Mr. W. J. Ancell, architect, of 3, Staples' Inn, London, who has personally directed the carrying out of the work.

The architect has made provision for 46 beds, of which 22 are in the large fever ward, 12 in small fever ward, 4 in an isolation ward, and 8 in convalescent ward. The entrance gates and lodges are placed at the end of the occupation road, by which the site is approached, and a forecourt leads centrally to the administrative buildings. Under the road a perfect scheme of sewerage has been carried out, connected with the Heston-Isleworth sewage farm. On the right at the north-east angle of the site and near the entrance is the convalescent home and discharging rooms, whilst deeper in the site towards the north is situated the small fever pavilion. The large fever pavilion is to the left of the administrative buildings, and midway between this and the small fever pavilion is the probationary block. These three pavilions have been planned so that they can be easily connected with the administrative block by means of covered ways, and wide roads for the ambulances lead from the gates to these buildings. At the extreme left of the site is placed the mortuary and *post-mortem* building, and to the right of this are the stables, laundry, disinfecting building, and the ambulance shed. Each pavilion is placed on a raised platform or terrace, and one foot above this is the general ground floor level of each ward. This will give a slight slope all round the pavilion, and by this means security from damp is obtained. Ample provision is made for future extension. All the wards are under direct supervision from the nurses' duty-rooms, and the provisions for heating and ventilation are of the most approved kind, as also are the arrangements for disinfecting clothing and bedding, and the steam laundry, mortuary, &c. In the fever pavilions, besides general wards, provision has been made in separation wards, either for paying patients or for acute cases where separation from the noise of a general ward is necessary.

A representative gathering assembled to meet the Duke of Cambridge, including the Mayor of Richmond, chairmen of District Councils, and a large concourse of Aldermen and Councillors.

Mr. PETER WATSON, J.P., after a few words of welcome to his Royal Highness, said the united population of the districts joined together was now about 60,000, and it was rapidly increasing, from which it would be seen that it was of the utmost importace that adequate hospital accommodation should be provided. Originally it was intended to have accommodation for forty beds, but it was found that forty-six could easily be provided, and the arrangement was altered accordingly. There were twenty-two beds in the large fever ward, twelve in the small fever ward, four in the isolation ward, and eight in the convalescent ward. Should additional accommodation be required in the future there was ample land available for an extension of the buildings. The total cost of the undertaking was under £17,000; and the hospital was conveniently situated for the district that it was intended to serve.

Following Mr. Watson's speech, an address was presented to the Duke, who then formally declared the hospital opened. After the inevitable photograph had been taken the company dispersed.

POLLUTING THE THAMES.—The Hambledon Rural District Council were on Saturday summoned before the magistrates by the Thames Conservancy Board for allowing the pollution of the tributaries of the Thames at Haslemere, Bramley, Wonersh, and Shalford. As steps are being taken to provide a drainage scheme, fines of £5 only were inflicted in the first three cases. At Shalford the matter has been dragging on for three years, and as there is no scheme the Council was fined £30.

WHOLESALE SURCHARGES IN RATES.—At an audit of the accounts of the Poor Law Union at Woodbridge, on Monday, Mr. W. Casson, the newly-appointed auditor for Suffolk, objected to the allowance which had been made to the extent of 30 per cent. to the owners of cottage property as illegal, and stated that he had found similar allowances being improperly made in every union which he had audited since he came to the district. He expected to have upwards of 500 surcharges in the county as the result of his half-year's work. The overseers present expressed great surprise.

Coming Municipal Men.

III.—MR. WILLIAM H. G. KIESER,

Assistant Borough Surveyer, Torquay.

MR. W. H. G. KIESER is a native of Torquay, and was educated at the Castle College, Torquay, where he obtained distinction in mathematics under the Cambridge Local Examinations. He was subsequently articled to Mr. Joseph Hall, Assoc. M. Inst. C.E., then surveyor and harbour engineer to the late Torquay Local Board, the articles being transferred to Mr. H. A. Garrett, Assoc. M. Inst. C.E., upon the removal of the former to take up the position of borough surveyor and waterworks engineer to the Cheltenham Corporation. During this period Mr. Kieser was successful under the South Kensington Science and Art Department in having works accepted for Art Teacher's Certificate and obtaining the post of assistant master at the Science and Art Schools, holding classes in building construction in addition to art subjects.

MR. WILLIAM H. G. KIESER.

In 1892 he was admitted a student of the Institution of Civil Engineers; in the early part of 1893 was appointed second assistant in the Borough Surveyor's department, and in the latter portion of the same year was appointed Assistant Borough Surveyor.

Mr. Kieser is a Professional Associate of the Surveyors' Institution, his drawings being retained for exhibition at that examination, and is also a graduate of the Incorporated Association of Municipal and County Engineers. The duties pertaining to the office he holds include the direction of office work in correspondence, preparation of plans, estimates, specifications, quantities, and supervision of execution of all works of road making and maintenance, paving, drainage, scavenging, lighting, maintenance of public baths, private street works, &c.; the examination of all plans for new buildings, inspection during construction, and testing of drains, &c., to same, the checking of wages sheets, preparation of reports on all matters, apportionments of costs of private street works; and in the absence of the Borough Surveyor he has taken full charge of the department on several occasions. As the Council executes its own work in its own workshops, as far as possible—employing a permanent staff of wheelwrights, carpenters, smiths, plumbers, painters, and other mechanics and labourers, the staff consisting of 120 men and 30 horses—it may be surmised that the office is by no means a sinecure.

During Mr. Kieser's connection with the borough, now extending over eight years, he has been associated with extensive works of drainage, chief amongst which are a system of surface-water drainage in the Avenue district, the laying of brick and pipe sewers to replace masonry culverts, and there has just been completed an extension of the main drainage system in the Upton district, involving a scheme for floods prevention, the whole of the plans, estimates, and specifications being prepared and the work carried out by the department by administration at a cost of £10,500. Some six years ago he drafted plans for and supervised erection of a temporary hospital for infectious diseases at the sanatorium as an addition to the permanent building, the maintenance of which rests with the Surveyor's Department.

He has also had much experience in street improvements, erection of public urinals above and under ground, laying out and maintenance of pleasure grounds (some 65 acres), maintenance and extensions of sea walls and foreshores, and every branch of a borough surveyor's duties in a first-class watering place. As affording some indication of the progress made by this popular resort it is worthy of note that during the past four years over 300 sets of plans of new buildings have been deposited for the approval of the Council, which include some 350 dwelling-houses, ten public buildings (bank, halls, clubs, &c.), and estate plans for five new estates, and exclusive of many additions and alterations to existing premises.

At the Torquay harbour very heavy and extensive improvements were commenced in 1890, and have proceeded continuously up to the present time, a total of £95,000 having been spent. They comprise the erection of a concrete groyne and quay wall, and the dredging with steam dredgers of the new harbour area thus formed, the laying out of public gardens upon the ground reclaimed thereby,

and the improvement of the Torbay-road adjoining by further concrete sea walls, and the formation and laying out of the Royal Terrace Gardens at the foot of the hill along which the road runs. The extension of quays and piers by timber piling and concrete walls, together with substantial masonry buildings for coal and fish stores, and a cargo shed in iron. The erection of a promenade pier 900ft. long, consisting of a timber deck carried on iron lattice girders and cast iron screw piles, and a timber landing stage for passenger steamships alongside, together with refreshment and waiting-room, lavatories, toll-boxes, bandstand, shelters, &c. Schemes have also been prepared for swimming baths, marine undercliff drive, new fish market, and extension of main sewer for purpose of draining a new building estate. The works now in hand comprise, in addition to the routine work, the erection of a four-cell refuse destructor, improvement of pier head by extension of shelters, &c., and erection of a new public urinal. It is pleasing to record, in conclusion, that on several occasions the members of the Council have expressed their unqualified approval of the manner in which Mr. Kieser carries out his duties.

LUNG COMPLAINTS AND THE SMOKE NUISANCE.

EVER since the causes of death have been tabulated in Halifax, says Dr. Ainley, Medical Officer of Health, Halifax, in his annual report recently to hand, those from the lungs have been shown to be a larger proportion of the total deaths in comparison with other towns. The remarks of Mr. Whiteley at the foot of his meteorological report may throw some light on this phenomenon. He says :—"These figures show that during the last twelve months the weather in Halifax has been colder and more damp, with higher rainfall and more rainy days than on the average in places near the same latitude ; as also that Halifax has had less sunshine than the others." The exact figures will show to what extent this is true. The rainfall at Huddersfield was 33·02in., Bradford 32·37in., Leeds 25·49in., and Halifax 34·04in. Compared with Leeds, Halifax has a very considerable excess of rain, and when one adds to this the very much lower temperature and a constantly smoke-laden atmosphere, one obtains the most perfect conditions for the production of those diseases of the respiratory organs which are so common in our midst. One could scarcely suggest that we should alter our geographical position, but the smoke, the most important factor of all, is within our control, or ought to be, and I have no hesitation in saying that if we had less the respiratory death-rate would be diminished. Not only does smoke aggravate such diseases as bronchitis by its irritant particles of carbon and sulphurous acid, but, as has been recently shown, intercepts or modifies those rays of the sun which destroy injurious micro-organisms and vitalise all that is healthy and good.

TATSFIELD, SURREY. — The Rural District Council of Godstone has instructed Messrs. Bailey-Denton, Son, and Lawford, of Westminster, to report as to the best means of providing an efficient water supply for the parish of Tatsfield.

Obituary.

SIR ROBERT RAWLINSON.

ONE by one the links connecting us with the early days of the present century are being snapped asunder, and the various professions and walks of life are losing those who were pioneers in the great changes which will ever mark this period as the most progressive in the world's history. The passing away of Mr. Gladstone, Sir Thomas Acland, and Mr. Spencer Walpole leaves but two men living who were in Parliament before the passing of the first Reform Bill. Following these, we have lost Lord Playfair—to whose researches and labours we are indebted for many useful discoveries—and Sir Robert Rawlinson, who has been described by some of the daily papers as the father of modern engineering sanitary science. Perhaps the title is hardly correct. He was a disciple of Chadwick, and the opportunities of his life enabled him to demonstrate in a remarkable manner the practicability of many of his great master's noble aspirations and theories.

Yet for all that Sir Robert was a wonderful man. Born two months after the late Mr. Gladstone, he inherited the indomitable Lancashire courage from his father, combined with the persistence of the Devonian from his mother. His educational advantages were of the most meagre description, and at an early age he had to help his father in the thousand and one details of a small village builder, working alternately as a stone mason, bricklayer, millwright, carpenter, sawyer, or navvy, as occasion might demand. Yet this was just the "grounding" to fit him for his after life. In an autobiographical note he says :—"When I was one-and-twenty I was residing at Liverpool, and entered the dock office under Jesse Hartley, the greatest dock engineer the world has ever seen. I remained there for five years, for the last three of which I was Hartley's confidential draughtsman and adviser. Then I went on to the London and Birmingham Railway, the Blisworth contract under Robert Stephenson. Stephenson was remarkably considerate, and indeed a gentleman, and treated me with almost brotherly kindness. I was in charge of the masonry. The railway was in a cutting about two miles long, and 60ft. deep through rock, with an intervening bed of clay, which had to be cut away and then filled in with masonry. I was then twenty-six."

But he was not destined to remain at railway constructing. At thirty he went back to Liverpool, taking charge of the Bridgewater Canal, and assisting in the building of St. George's Hall. In 1847 he took the world by surprise when he suggested that Liverpool should secure the Bala Lake for supplying the city with water. The people were not ready for such heroic schemes, but what was then deemed impossible is practically an accomplished fact to-day. The only difference is the water comes from Vyrnwy instead of Bala.

The year 1848, however, was the turning point in Rawlinson's life. On the passing of the Public Health Act, he definitely entered upon a career as a pioneer in sanitary engineering, up to that period a much neglected branch of the profession. He obtained an appointment as one of the first Superintending Inspectors under the Act of 1848, and at

Dover he made the first inspection in accordance with the provisions of the Statute, and wrote the first report. After this, he inspected a number of thickly-populated areas, including several of the principal towns of the kingdom. A widespread boon was conferred by the new system of main drainage which he planned for the use of towns, and which has been universally adopted. The deplorable condition of the British Army in the East during the Crimean campaign called for the serious intervention of the Government, and a Sanitary Commission was sent out early in 1855, as recommended by the then Board of Health, the members of the Commission consisting of Dr. John Sutherland, Dr. Hector Gavin, and Mr. Rawlinson. So terrible was the sickness which had to be dealt with that the number of men who were disabled by preventable disease amounted to more than one-third of the whole strength of the army which went out from England.

On arriving at Constantinople the Commission at once set to work, and the result of their labours is thus described by the biographer of Sir Robert in "Men and Women of the Time:" "Works were begun immediately, both at the great hospitals situated on the Bosphorus and at the camp in the Crimea, such as cleansing, ventilating, and furnishing purer water. The returns from the four great hospitals on the Bosphorus, containing upwards of 4000 sick British soldiers, showed March 17th, 1855, an average rate of mortality equal to 8·61 per cent. per month of the sick, which mortality was reduced by June 30th of the same year to 1·01 per cent. per month. In the Crimea, during the winter (1854—5) previous to the advent of the Sanitary Commission, the losses in some regiments at the front had ranged for three months as high as 70 per cent., a mortality unexampled even in the worst of any former wars; by the end of the summer (1855) the entire British Army in the Crimea was placed in a better state of health, and had a lower rate of mortality than it had ever experienced in barracks at home." For services like these Sir Robert Rawlinson received warm acknowledgment from many quarters, not only at home, but also from the German Emperor, Prince Bismarck, Count Moltke, and the Secretary of the Sanitary Commission of North America at the end of the Civil War.

Another field of energy, says a writer in the *Standard*, in which the late Sir R. Rawlinson laboured would seem somewhat removed from his functions as a sanitary engineer, though in reality there was no such severance. During the cotton famine caused by the American War, he was sent to Lancashire by Lord Palmerston's Government as Engineer Commissioner to organise, under the President of the Poor Law Board, "work for wages" amongst the distressed cotton operatives. The paralysis which had befallen a great national industry was happily turned to account by the execution of extensive sanitary works in the cotton districts, thereby conferring a permanent benefit on the population. The experience so gained had a yet further effect, by leading to the passing of an Act by which the Exchequer Loan Commissioners can advance money to Local Authorities for the carrying out of town improvements. The deceased engineer served on several Royal Commissions, and was engaged in numerous inquiries of a sanitary character. He was one of the Commissioners appointed to inquire into the best mode of distributing the sewage of towns, and applying it to beneficial and profitable uses. We find him reporting, many years ago, that the only safe mode of disposing of town sewage was to filter it through land. Its agricultural value, he remarked, would depend on local contingencies, but, where favourable conditions existed and works were cheap, the application of sewage for agricultural uses, he believed, would pay. Where conditions were not favourable, he suggested that a small rate in aid would be required. Some further light has dawned on the subject since that report was written, and the great hopes entertained at one time with regard to sewage irrigation have generally given place to methods for practically throwing the sewage away after first rendering it innocuous. "Filtration through land," Sir R. Rawlinson recommended as "the only safe method. If the rivers of England are to be purified it must be by intercepting canals to receive all fluid refuse, and convey it to land for purposes of irrigation." On this principle, he made the formidable proposition that "the River Thames requires intercepting canals through its entire length." But we have now chemical processes and a sludge flotilla, so far as London is concerned. It may be remembered that, at a time when the irrigation theory largely prevailed, Sir R. Rawlinson held an official inquiry into the existence of certain obstructions alleged to be created in the river channel by the discharge of the metropolitan sewage at Barking. The facts remained somewat obscure, though allegations abounded, and the controversy is now ended by carrying away the solid residuum to the German Ocean. In his latter days, however, even Sir Robert admitted that finality had not been reached in the best method of treating sewage, and he manifested great interest in recent important developments.

Sir R. Rawlinson had a wide official experience respecting the drainage of towns, the treatment of sewage, the construction of waterworks, and everything of an engineering character that had reference to the public health. When a Royal Commission was created to inquire into the pollution of rivers, he was appointed chairman, and he subsequently became Commissioner to grant certificates under the Rivers Pollution Prevention Act. He was also a member of the Army Sanitary Committee, dealing with all the health conditions connected with barracks, hospitals, and stations for the army, both at home and abroad. For nearly forty years he held the post of Chief Engineering Inspector under the Local Government Board, and on resigning the appointment he became vice-president of the Irish Board, from which he retired in 1891. He was created a C.B. in 1865, his knighthood being obtained in 1883, and the rank of K.C.B. in 1888. He was a member of the Council of the Institute of Civil Engineers, being its president in 1894, and a vice-president of the Society of Arts.

For the last few years, Sir Robert Rawlinson lived in retirement in a house at Kensington, crowded with pleasant memories and associations. His strength began to fail him this year, and he passed away on Tuesday, May 31st. He was buried on Saturday last at Brompton, and the funeral was attended by many of his former colleagues and the representatives of the numerous societies to which he had been attached.

DR. JOHN BARRITT MELSON.

THE death took place at Lapworth, last week, of Dr. John Barritt Melson, in his eighty-seventh year. He was the son of a Wesleyan minister, and, receiving his early training at the Woodhouse-grove College of that body, took an earnest interest in Wesleyanism throughout his life. He graduated at Oxford, and for a special dissection made while an undergraduate, was elected a Fellow of the Cambridge Philosophical Society. Dr. Melson was apprenticed and commenced his practice in Birmingham, and whilst Professor of Natural Philosophy and Hygiene at Queen's College, he had as students the late Archbishop of Canterbury and Dr. Westcott, the present Bishop of Durham. When quite a young man Dr. Melson was placed on the commission of the peace, and at the time of his death he was the senior magistrate for the city. At the request of Sir Isambard Brunel he made the differential calculus of the lateral oscillation of engine axles, and assisted him in devising improvements to prevent the wheels leaving the rails when travelling beyond forty-five miles an hour. About the same time Professor Faraday relegated to Dr. Melson the question of the economical value of electricity as a motive power. He was also the first to introduce into Birmingham photography, electro-plating, and telegraphy. He had the first daguerreotype that was taken, which attracted a considerable amount of interest more than half a century ago. He was well known, not only in Birmingham, but throughout the country, and was highly esteemed.

MR. WILLIAM ILIFFE, DERBY.

THE death occurred, on last Friday night, of Mr. William Iliffe, Medical Officer for the borough of Derby, and its startling suddenness made the sad news harder to realise for his many friends. He had been somewhat unwell for a few days past, but was able to attend to his duties as usual, and on Friday he expressed himself as feeling considerably better. He dined with his family at seven o'clock, and spent the evening smoking and reading. While sitting in his arm-chair, at about ten o'clock, he suddenly made a noise in his throat, and, without any other warning, fell back and expired. Medical aid was at hand almost immediately, but life was pronounced to be extinct, and Dr. Daniells, of Osmaston-road, led the coroner's jury at the inquest, which was held on the body on Saturday afternoon, to return a verdict to the effect that death was due to syncope. Mr. Iliffe, who was 53 years of age, was a native of Nuneaton, and before coming to Derby, some twenty-eight years ago, he held a staff appointment at the Birmingham Borough Lunatic Asylum. In 1876 he was appointed to the post of Medical Officer of Health for Derby, under the Act which had then just come into operation, but the salary was little more than nominal, and he engaged in an extensive private practice in partnership with his brother, Mr. Frank Iliffe, of The Wardwick, Derby. In 1895 the Corporation successfully endeavoured to secure his undivided services, and results have proved that a more competent or zealous director of sanitary affairs could not have been desired. Under Mr. Iliffe's fostering care Derby has assumed a very enviable place among the healthy communities of the kingdom, sharing with Brighton the honour of possessing the lowest death-rate.

TYPHOID FEVER AND ITS PREVENTION.

LECTURE BY DR. CHRISTOPHER CHILDS.

UNDER the auspices of the National Health Society, which has for its object the diffusion by various approved methods of knowledge of sanitation, the first of two lectures on Public Health was given at 20, Hanover-square, W., on Tuesday, by Dr. Christopher Childs, M.A., M.D. Oxon., D.P.H., Lecturer on Bacteriology in relation to Hygiene, at the University College, his subject being "Our present knowledge with regard to the Bacteriology of Typhoid Fever, and the application of this knowledge to the prevention of the disease." Sir Richard Thorne Thorne, C.B., M.B., F.R.S., the Chairman of the Council of the National Health Society, occupied the chair, and those present included a large number of lecturers, training students, and nurses. The lecture was illustrated by oxy-hydrogen slides, kindly lent by Dr. Slater and Dr. Spitter, of St. George's Hospital, and exhibited by Mr. Baker.

Dr. CHILDS said it was an honour and privilege to address the members of the National Health Society upon such an important subject, but at the same time he was glad to have the opportunity of speaking to those who, through the agency of that great Society, were engaged in the honourable task of instructing the people in the art and science of domestic hygiene and nursing. For he hoped to enlist their sympathy and co-operation, and the support of the Society in concentrating and increasing the efforts being made in various directions to exterminate this dread disease. At the present time in England and Wales alone between 5000 and 6000 people died annually from typhoid fever, and yet typhoid was an eminently preventable disease. If full and proper use were made of the knowledge now gained with regard to it, its causes and the means of prevention, not only might nearly 5000 lives be saved every year, but the prolonged sickness and suffering of some 30,000 to 50,000 individuals might be prevented, and the disease exterminated altogether. Everyone could help in preventing these terrible yearly sacrifices to ignorance and indifference by learning the ways by which typhoid fever spreads, and the means by which it may be prevented, by taking care to observe the necessary precautions with regard to cleanliness and disinfection, if a case of typhoid fever occur in a family amongst those under his or her charge; by making sure that his house and its immediate surroundings are kept free from pollution with foul matter and from those defects through which the typhoid fever poison may gain access to the inmates; by insisting that the soil on which he lives and the air which he breathes, or the water which he consumes, and other food, shall not be polluted through the carelessness or ignorance of others; and by giving support and encouragement to those engaged in trying to obtain more complete and effective legislation by which such pollution may be prevented. Typhoid fever, according to the best authorities, is caused by living creatures called typhoid bacilli, creatures so small that they can only be seen through the most powerful microscope, so small that millions of them may be crowded in a single drop of fluid or a few grains of soil. From a patient suffering from

typhoid fever the bacilli are given off in countless myriads, chiefly in the discharges from the bowel, but also in the urine; if these bacilli are allowed to find their way into the surroundings or into the food of man—such as soil, water, or milk—they can multiply with marvellous rapidity, from one to over thirty millions in forty-eight hours, and if they find entrance into the body of man they can multiply in the same way, and produce the disease we know as typhoid or enteric fever. These bacilli might be conveyed in various ways to individuals, such as handling the body, clothing, bedding, utensils, and other things which have been polluted with the discharges of the typhoid fever patients. Such cases, however, were rare, and need never occur if proper and sufficient care be taken with regard to cleanliness; the disease could also be conveyed through the air coming either from the soil or from drains, cesspits, and other deposits, which has been contaminated with the discharges from patients; through the ordinary food, especially drinking water and milk which had been exposed to air contaminated with the bacilli; it was probable also that the poison is sometimes conveyed through oysters and shellfish, ices, watercress, and other food materials which have been in contact with polluted water, and had not been boiled before being eaten. In spite of the additional knowledge which has been gained during the last forty years with regard to the nature and causes of typhoid, comparatively little has been definitely established with regard to the life history of the typhoid bacillus after it has left the body of the patient. This parasite has practically not been found in the surroundings of man, neither in air nor soil, nor water nor food, nor in the sewers or deposits of filth which constantly receive countless hosts of this bacilli, excepting in those cases where they have been implanted for the purpose of experiment, and in certain rare instances where they have been detected in connection with some typhoid outbreak. When this living poison contained in the discharges and urine of a typhoid fever patient has been committed to the drains, to the soil, or to the water, it is almost impossible to detect it again, or to learn what has become of it with the means and methods at present at our disposal. Consequently, almost the only protection from invasion by this secret foe after it has been removed from the patient lay in those precautions by which it is prevented from infecting air, soil, water, and food, and in those measures which are used, often with such imperfect success, for removing or destroying the typhoid bacilli after they had gained access to the body. On the other hand, up to the time when the typhoid poison has passed from under the charge of the nurse, we have it under our control and power; we know where it is, and the means by which we may utterly destroy its vitality and capability for mischief. The honour and responsibility of holding and guarding the first line of defence against this ubiquitous and destructive enemy belongs to the nurses and attendants upon typhoid fever patients, while the difficulty of detecting and battling with the foe after the bacilli has been allowed to pass the first barrier is multiplied to an incalculable extent. In his opinion sufficient attention has not been given to the prevention of typhoid fever, and the powerful means we possess for protecting ourselves by cleanliness and disinfection of the patient and his surroundings. For this reason he would plead that every facility should be given to nurses for the complete and economical disinfection of typhoid patients, and that systematic and complete methods should be adopted wherever typhoid patients are treated. He appealed to them and all nurses, as well as those interested in nursing, to realise the great responsibility incurred in nursing a typhoid fever patient, to recognise the power possessed of destroying the living poison before it can escape, and to neglect no precaution which will ensure the protection of others from the disease. The difficulty of studying the history of the typhoid bacillus after it has found access to drinking water, soil, milk, was that it becomes obscured by the innumerable other organisms which are to be found, and they render it impossible to separate the typhoid bacillus. It had been shown, however, by Professor Sidney Martin, that the typhoid bacillus may live and thrive and spread in soil for at least a year, under conditions obtainable in a laboratory, especially in polluted soil; whilst Dr. Robinson, of Sheffield, had shown that it exhibits similar powers in natural soil exposed to all the vicissitudes of climate and season which obtain in this country. The typhoid bacillus was not killed by prolonged freezing, but it is destroyed at about 60 deg. Cent. or 140 deg. Fah. in half an hour, and at the temperature of boiling water. In the dry state it could only be killed at higher temperature. This linen could be completely disinfected by boiling for several minutes to ensure complete boiling through every part of the fabric. The bacillus was also killed by moderately weak disinfectants, such as carbolic acid and perchloride of mercury. The latter alone could not be recommended for disinfection of any albuminous material unless some strong acid is also added to it, but in the absence of albuminous material 1 part of mercury perchloride in 1000 of the fluid soon destroys the bacilli. In clear liquids, such as broth and wine, 1 part of carbolic acid in 200 of the fluid will also kill. A solution containing 1 part of mercury perchloride in 500 of water may be used for the disinfection of the urine of a patient or washing the hands of the nurse. But in disinfecting linen, evacuations, &c., time must be allowed for complete penetration. In all cases it is imperative to err on the safe side and to employ far stronger disinfectants and longer time than may appear necessary. After studying the methods employed in most of the large London hospitals, the information being placed most courteously and freely at his disposal by the medical officers, matrons, and nurses, he had ventured to formulate a series of rules such as might be employed in hospitals or in private houses or cottages. Those rules did not pretend to any originality, but might be of service where systematic means for the treatment of typhoid fever patients did not exist. These rules dealt with the means for preserving cleanliness in every detail, disinfection, feeding utensils, &c., and Dr. Childs concluded by pointing out that the difficulty lay in the fact that the knowledge with regard to the typhoid bacillus did not permit of their speaking obsolutely about any of the things recommended, but the wisdom of taking every possible precaution was manifest.

Dr. Childs was heartily thanked for his lecture.

Sanitary Inspectors' Associations.

NORTH-WESTERN AND MIDLAND.

THE usual monthly meeting of the Association was held on Saturday last, the 4th inst. Mr. William Stansfield, chairman of Council, presided over a good attendance of members.

After the transaction of the routine business, the CHAIRMAN called upon Mr. J. T. Quinton, District Sanitary Inspector, Liverpool, to read his paper on "Combined Drainage: Drain or Sewer." The paper was of a most interesting and practical character, the writer evincing marked ability in the handling of an exceedingly difficult and complex subject.

Mr. QUINTON referred at the outset to the definitions of "drain" and "sewer," as given in the 1875 Act, and pointed out that it had taken something like thirty-two years to amend the definitions as originally given, and that when amended the difficulties had only been increased, as Section 19 of the Amendment Act of 1890 had made the law on the point even more absurd than before. A pipe which was used for the drainage of more than one building still remained a sewer, unless (1) written complaint had been made to the Local Authority that a drain was a nuisance or injurious to health; (2) that the houses drained by the pipes belonged to different owners; (3) that it was a single private drain; (4) that the said private drain was connected with a public sewer. The first, second, and fourth provisos were tolerably clear, but not so the third, the word "private" indicating that the framers of the Act appeared to have had cognisance of two classes of drains. Mr. Quinton then dealt with the question of combined drainage in the metropolis, and entered into the various definitions of "curtilage."

The second part of the paper was devoted to a consideration of the legal decisions which had been given on this much-vexed question, the full text of the judgments being given in the cases of Travis *v.* Uttley, Self *v.* Hove Commissioners, Hill *v.* Hair, Mayor of Eastbourne *v.* Bradford, Reg. *v.* Mayor of Hastings, Seal *v.* Merthyr Tydfil, and two local cases recently adjudicated on by the stipendiary magistrate of Liverpool. The well-known decisions affecting the metropolis in the cases of the Vestry of St. Martin's *v.* Bird, Pithow *v.* St. Leonard's Vestry, Shoreditch; Vestry of St. Leonard's, Shoreditch, *v.* Phelan; Kershaw *v.* Taylor, Appleyard *v.* Lambeth Vestry. Mr. Quinton pleaded, in conclusion, for the much-needed consolidation and simplification of the Public Health Acts.

At the close of the paper a discussion was initiated by the CHAIRMAN, and continued by Messrs. WM. URQUHART, N. COATES, W. WOODWARD, the HON. SECRETARY, &c., Mr. Quinton being warmly complimented on his "maiden" effort.

With Mr. QUINTON'S reply the proceedings terminated.

HULL.—As a precautionary measure against the introduction of small-pox into the city, the Guardians have decided that all tramps should be medically examined.

General News.

BOLTON.—A set of plans has been passed for new public baths to be erected at a cost of £5250, this being the first of a series to be placed in various parts of the borough.

WIVENHOE, ESSEX. — The Urban District Council, at a recent special meeting, unanimously resolved to apply to the Local Government Board for sanction to borrow £6000 for works of water supply.

EDMONTON.—The Urban District Council has decided, subject to the approval of the Local Government Board, that a permanent building for cases of infectious disease be erected at a cost of £6400.

BRIGHOUSE.—At the last monthly meeting of the Brighouse School Board it was reported that an epidemic of measles had broken out in the district, and that one of the schools had been closed in consequence.

ABERDEEN. — The Water Committee of the Town Council recently inspected three of the four irrigation farms on the Deeside. The Committee found everything at the farms in a most satisfactory condition.

LONDON.—The Corporation is about to appoint a Sanitary Inspector at a salary of £140 per annum. He will also be required to act as Inspector under the Food and Drugs Act. Further particulars may be obtained of the Town Clerk, at the Guildhall.

TYNEMOUTH.—A representative meeting of the property owners and ratepayers was held recently, when the following resolution was passed:—"That this meeting of the inhabitants of Spital Dene and Tynemouth protests against Spital Dene being made a deposit for the filthy town refuse of the borough."

SOUTHGATE.—The District Council has unanimously decided, on the recommendation of the Hospital Committee, that a permanent hospital be erected, in accordance with plans prepared, as soon as the necessary sanction has been obtained, at a cost of £6400, the Clerk to discuss with the Edmonton Council and others interested what arrangements it might be desirable to enter into with them.

LONDON.—Dr. S. Saunders, Medical Officer of Health for the City, in his last monthly report to the Corporation, stated that the death-rate was 15·4 per 1000 per annum of the population. Eleven notifications of infectious disease had been received in accordance with Section 55 of the Public Health (London) Act, 1891. Certain smoke nuisances had been reported, including three at the General Post-office and one at the Bank of England. At the markets and slaughter-houses 67 ton 16 cwt. of meat had been seized and destroyed as unfit for human food. The seizures were 1881 in all. The total quantity of meat delivered at the markets in the month was 35,577 tons. The weight of meat seized was much in excess of that for any corresponding previous period in late years. That arose from a large quantity of American pork having arrived in this country in a bad condition.

SOUTHAM. — The Rural District Council has called in Mr. J. E. Willcox, C.E., of Birmingham, to prepare a scheme for the water supply of the district.

BUCKINGHAMSHIRE. — The Newport Pagnell Urban District Council has accepted the tender of Messrs. G. Waller and Sons, of Stroud, for the new engines and pump, designed by Messrs. D. Balfour and Son, of London and Newcastle, required at the town waterworks, which, owing to their increased power, will enable the supply to be delivered in six hours.

DURHAM.—The scheme of water supply submitted by the Easington Rural District Council for Castle Eden Colliery has been approved by the Local Government Board. The water is pumped at Wingate from the sand feeder up into a reservoir, and then is to be conveyed a distance of three miles in cast iron main, when it will be distributed over the town. The scheme has been designed by Messrs. D. Balfour and Son, of London and Newcastle.

LONDON.—The Home Secretary has issued an order under the Factory and Workshop Act certifying that in his opinion the manufacture and decoration of earthenware and china are dangerous or injurious to health. Now the Chief Inspector can serve on the manufacturers of these articles notices either proposing such special rules or requiring the adoption of such special measures as appear to be reasonably practical and to meet the necessities of the case.

CRICH.—A few months ago the Belper Rural District Council invited competitive schemes for supplying the parish of Crich with water—a district containing about 3000 population. Ten schemes were submitted, engineers from London, Brighton, Birmingham, and Yorkshire competing. The Council decided that the scheme submitted by Mr. Harry W. Taylor, of Newcastle-on-Tyne, was the most suitable, and this was accordingly adopted. Mr. Taylor has been engaged as engineer for the execution of the work.

LANCASTER.—At the Lancaster Rural Council meeting, on Saturday, a letter was read from the Local Government Board stating that it was satisfied from the information before it, that the work devolving upon Mr. Jowitt, in his capacity as surveyor, did not leave him sufficient time to fulfil the duties of Inspector of Nuisances. The Board was further of opinion that a district comprising twenty-one parishes and townships, with 51,174 acres, should have a properly qualified man to devote his whole time to the work of an Inspector of Nuisances. The Council decided to take no action in the matter for the present.

DUNDEE.—An estimate of the amount of water used for police, public health, and sanitary purposes in Dundee, has been prepared by Mr. George Baxter, the Engineer. The total value of the water so used is £4183 3s. 4d., but the Town Council is only charged £1300 of this sum. For street watering, &c., water to the value of £147 is required; horse troughs cost for supply, £378; fountains, £285 (Albert Fountain, £180); police offices, hospitals, &c., £175; skating pond, £105; fish market, £55; and public baths and washing-houses, £554. The largest single sum charged is that for the supply of conveniences, £1632.

LLANIDLOES. — A Local Government Board inquiry has been held recently into the application of the Town Council to borrow £12,000 for the purpose of carrying out the scheme of Messrs. F. Beesley and Son for the water supply of the borough, and other improvements.

BEDALE.—At a meeting held on 31st May the Bedale Rural District Council had under consideration a scheme of water supply prepared by Messrs. Fairbank and Son, civil engineers, of York. The scheme is to collect the water arising from springs in "Keeper's Wood," about 1¼ mile from Bedale, and to conduct the same to a point close to Bedale, and to utilise the pressure thus gained to force up a part of the water by two rams working in series to a covered storage reservoir on high ground about a quarter of a mile north of Bedale, from whence it will flow by gravitation to supply the highest houses in the town. The usual valves, hydrants, and consumer services will be provided, and the cost of the whole scheme is estimated at £2850. The annual expenditure, including repayment of loan and interest, is estimated at £179. The Council approved of the scheme and authorised a special Committee to carry out the work.

Personal.

PROFESSOR R. W. BOYCE has been appointed an additional Analyst for the city of Liverpool.

MR. ED. ASTBURY has been appointed Inspector of Nuisances for the urban district of Buckley.

MR. J. CAMPBELL has been appointed Inspector of Nuisances for the urban district of Wallsend.

MR. W. J. E. DAVIES has been appointed Assistant Medical Officer of the Chelsea Infirmary.

MR. L. M. WITHERS has been appointed Inspector of Nuisances for the rural district of Rugby.

MR. H. D. A. ELLIS has been appointed Medical Officer of Health for the urban district of Ambleside.

MR. L. M. WITHERS has been appointed Inspector of Nuisances for the rural district of Crick.

MR. J. T. GREY has been appointed Medical Officer for the No. 4 district of Hollingbourn union.

MR. CHAS. G. SEXTON has been appointed Sanitary Inspector for the Kensington sanitary district.

MR. CHARLES J. MYERS has been appointed Medical Officer of Health for the rural district of Louth.

MR. THOMAS PIERCE has been appointed Inspector of Nuisances for the borough of Marlborough.

MR. W. A. MILLWARD has been appointed Inspector of Nuisances for the urban district of Llandrindod Wells.

MR. WEAVER, engineer to the Gloucester Corporation, has been appointed Borough Surveyor to the Lynn Town Council.

MR. J. W. HARDY, Assoc. Sanitary Institute, has been appointed Sanitary Inspector, Fruit Department, to the Hull Corporation.

DRS. A. NEWSHOLME, J. F. W. Tatham, and B. A. Whitelegge have been elected Fellows of the Royal College of Physicians of London.

THE Local Government Board has sanctioned the appointment of Mr. R. Arthur Thomas as Inspector of Nuisances for the Menai Bridge urban district.

MR. ROBERT DRYDEN, Edinburgh, has been appointed Sanitary Inspector, Water Officer, and Surveyor for the Dalkeith burgh, at a salary of £102 per annum.

THE Hexham Rural District Council has engaged Mr. Harry W. Taylor, A.M.I.C.E., of St. Nicholas Chambers, Newcastle-on-Tyne, to prepare a scheme for the water supply of Haydon Bridge, Northumberland.

THE Crewe Town Council has appointed Dr. Meredith Young, M.D., Mast. Surg., D.P.H., Medical Officer of Health, and Medical Superintendent of the Corporation Hospitals for a further term of three years, and has increased the salary from £300 to £350.

THE Local Government Board has sanctioned the appointment of Mr. Charles Brooks as Medical Officer of the Gerard's-cross district of Eton union, at a salary of £10 per annum; also the appointment of Mr. W. S. Dibbs as Medical Officer of the Hedgerley district, at a salary of £20 per annum.

Sewerage Schemes.

[TO MUNICIPAL ENGINEERS AND SURVEYORS.—The Editor will be pleased to receive items for publication relating to sewerage schemes projected or inaugurated, together with explanatory diagrams or photographs. The former should be drawn and lettered in black ink.]

THE Stourport Urban District Council has decided to proceed with the trial of a sewage filter in the Bridge Meadow.

THE Local Government Board has sanctioned the borrowing of £2000 for the sewerage scheme at Carisbrooke, Newport.

THE Wigton Rural District Council has recommended the Parish Council to apply for £200 for sewerage works for Caldbeck.

THE Epsom Rural District Council has resolved to apply for a loan of £22,000 for the drainage of Cobham, in accordance with the plans of Messrs. Fredk. Beesley and Son.

THE members of the Garm and Ogmore Valleys Urban District Council have gone on a tour of inspection. They purpose visiting Exeter, London, and some other places, for the purpose of seeing how the various towns to be visited deal with sewage. The septic system is being advocated, and the Council has decided to see for itself the various systems at work.

THE Handsworth District Council has resolved to apply to the Leeds Corporation for permission to inspect the sewerage scheme in operation there.

AGREEMENTS and plans are to be prepared for the sewage disposal scheme at Warminster, according to a decision arrived at by a special meeting of the Urban District Council.

THE River Pollution Prevention Committee of Durham City Council has reported that it has instructed Messrs. Lomax, the engineers in connection with the city sewerage scheme, to forward the amended scheme at once to the Local Government Board.

THE Rural District Council of the Isle of Thanet has at length decided that Birchington-on-Sea, which is rapidly growing in public favour, shall be provided with an efficient system of sewerage, and have instructed Messrs. Bailey-Denton, Son, and Lawford, of Westminster, to report in detail thereon.

AT the last meeting of the Wimbledon Urban District Council the Road, Drainage, and Farm Committee presented the farm bailiff's statement of accounts for the year ending March 31st last. It showed a profit balance of £130 17s. 5d., the total receipts amounting to £1113 2s. 7d., and included the following:—Grass, 389 17s. 6d.; vegetables, £422 10s.; mangolds, £170 4s. 1d.; cows, calves, and milk, £88 11s.; osiers, £20. The principal item of expenditure was £807 12s. 4d. wages.

AT the last quarterly meeting of the Staffordshire County Council, the report of Mr. J. E. Wilcox, C.E., of Birmingham, with respect to the drainage of the county asylum was considered, and it was decided to carry out his scheme for an entirely new system of sewerage and surface-water drainage for the asylum at an estimated cost of £6000, the work being necessitated by the present unsatisfactory sanitary arrangements and the fact that the Stafford Corporation refuses to admit surface water into its new system of sewers.

A LOCAL Government Board inquiry has been held at Leicester in reference to applications by the Town Council for sanction to borrow £3600 for sewerage purposes, £797 for the purchase of land for the purpose of public baths, and £1310 for street improvements. With reference to the loan for sewerage, it was stated that the Corporation had determined to construct a main intercepting sewer along the Evington Valley, taking the sewage from the eastern side of London-road, and of buildings erected on the land through which the new sewer would run. At the present time the sewage from the eastern side of London-road had to be pumped to the Knighton pumping station, which it was now proposed to abolish. The new arrangement would be that the sewage would be carried by gravitation to the Belgrave Pumping Station, and thence pumped on to the Beaumont Leys Farm. It was estimated that by carrying out this scheme, and abolishing the pumping station at Knighton, there would be a saving of at least £200 a year.

THE Rural District Council of Penistone has decided to forward to the Local Government Board the plans and estimates of the Langsett sewerage scheme.

THE new Sale sewage works, constructed at a cost of some £26,000, which, for their size, are among the most complete of their kind in the kingdom, were formally opened on Wednesday, the 1st inst. Satisfaction is felt that the scheme, which for various reasons has met with considerable delay, has at length been put into operation, and no doubt is felt that the works will fully meet the requirements of the Mersey and Irwell Joint Committee.

THE long-pending dispute between the Brigg Urban District Council and Mr. Cary-Elwes as to the amount to be paid for five acres of land near the bank of the river Aucholme required by the Council for sewage works, has been settled by arbitration. Valuers engaged by the Council stated that the land was only worth £660, whereas Mr. Cary-Elwes's valuers put the amount at £1641. The award given by Sir John Rolleston, the sole arbitrator, is that the Council has to pay £963 12s. 6d. for the land.

THE main drainage of Dublin at the north side may now be said to be completed. The Clontarf section has been carried out with despatch. The heaviest part of this undertaking was the tunnelling under the Royal Canal and the Tolka. The work has now been finished along the northern line of quays, and the Kilmainham section is well advanced. There was a good deal of difficulty in dealing with this portion of the work, as provision had to be made for the emptying into the river of the existing drainage until the main sewers are completed and ready to receive the discharge. A commencement has now been made at the south side, below O'Connell Bridge. Messrs. H. and J. Martin, the contractors, are carrying on the work rapidly and well.

ON the invitation of Hospital-master Laing, convener of the Brechin Sewage Farm Committee, the Police Commissioners recently paid a visit of inspection to the sewage farm, where, by means of filtration beds, Mr. Laing has effected some very desirable improvements in connection with the purifying and disposal of the town's sewage. Samples were taken of the sewage as it enters the river at three different parts from the new settling ponds; also of the river pure and as mixed with the sewage. The samples have been submitted to an analyst, whose report will be awaited with interest, as some of the Commissioners, it is understood, are still somewhat dubious as to the benefit or otherwise to be derived from the new improvements, the money for which has been dealt out somewhat sparingly to the Sewage Convener.

NOTICE.—The Annual Subscription to this Journal has been raised to 12s. 6d. to all NEW Subscribers. NO ADVANCE will be made to our friends whose names were entered on our Subscription list prior to March 31st, so long as they continue to subscribe.

Lighting.

A LOCAL Government Board inquiry has been held at Watford with reference to an application for sanction to borrow £21,000 for electric lighting purposes.

AT a special meeting of the Peebles Town Council it was resolved to offer to buy the whole of the works and plant of the Gas Company at £157 10s. per £100 of stock.

IN spite of the opposition of the Gas Light and Coke Company, the application of the Barking District Council to the Local Government Board for an electric lighting loan has been granted.

A LOCAL Government Board inquiry has been held at Colwyn Bay relative to an application made by the Urban District Council for sanction to borrow £2000, for the purpose of lighting the promenade with electricity.

THE Dover Electricity Supply Company announce that from July 1st next the scale of charges will be revised. The reduction will be roughly stated from one-fifth to one-fourth less than the present prices to the average consumer.

AN Order has been issued by the Metropolitan Gas Referees to the effect that for the future the 10-candle pentane air-gas flame is to be used as the standard of measurement for illuminating power at the twenty-three gas-testing stations in the metropolis.

PROFESSOR KENNEDY, who has been retained by the Devonport Town Council, has visited the borough and considered the position of a site for an electric station, and is of opinion that the site adjoining and to the east of the Corporation property at Pottery Quay is large enough for the purpose, both for power and light supply.

IN connection with the prospective erection of the new gasworks at Granton by the Edinburgh and Leith Gas Commissioners, it has been arranged, we understand, that deputations of the Commissioners shall visit towns both at home and abroad to see the latest installations of gas plant for the manufacture of gas. Four deputations, with four members in each, have been nominated.

AT a recent meeting of the Brighton Town Council the report of the Lighting Committee was adopted, containing estimate of further capital required for 1898—9, and recommending that application be made to the Local Government Board for sanction to borrow for a period of twenty-five years, on the security of the general district rates, the sum of £56,300 for the purposes of the electricity undertaking.

THE Corporation of Leeds has obtained its Order for the taking over of the undertaking of the Yorkshire House-to-House Electricity Company, Limited.

A LOCAL Government Board inquiry was held at Darwen recently into an application by the Corporation for powers to borrow £30,000 for electric lighting, and other sums for other purposes.

AT a recent meeting of the Wimbledon Urban District Council Mr. A. H. Preece submitted his report and plans on the question of the combination of the refuse destructor in the boiler-house of the electric light works. The total estimated expense was £4650. It was decided to make an application to the Local Covernment Board for sanction to borrow £5000. A number of tenders were recently obtained by the Surveyor from certain firms for the electric wiring of the depôt buildings in Queen's-road, but the Council has resolved to return these tenders and advertise generally for estimates. The cost is about £150.

THE Monifieth Gas Light Company, Limited, has been formed with a capital of £5000, divided into 1000 4 per cent. cumulative preference shares of £1 each and 4000 ordinary shares of £1 each, all of which are offered for subscription, but in regard to the latter it is proposed meantime only to take payment of 10s. per share. The object of the company is to acquire ground, property, and other subjects, and erecting and establishing gasworks, with all the necessary equipments for manufacturing and supplying gas to meet the requirements of householders, merchants, and others within the burgh of Monifieth and neighbourhood, and to supply public lighting.

WE learn that the Board of Trade has issued a Provisional Order to the Urban District Council of Barnes empowering it to supply electricity throughout the whole of the area within its jurisdiction, but excluding Hammersmith-bridge. The Order contains the usual provisions limiting the profit to be made by the Council to 5 per cent., and for the application of the surplus to the improvement of the district or to the reduction of the capital moneys borrowed for electricity purposes. The Board reserves the right to revoke this Order should the Council fail to lay distributing mains through certain specified streets within two years from its confirmation by Parliament.

THE Board of Trade has issued Provisional Orders to the Vestry of Bermondsey and the Vestry of St. Marylebone, empowering these bodies to supply electricity "for all public and private purposes" throughout the whole area of their respective districts. The Order sets forth a list of the streets along which distributing mains must be laid within a period of two years, and it is provided that in the event of the surplus revenue exceeding 5 per cent. on the capital expended on the works, the Vestries "shall make a rateable reduction in the charge" for electricity. The surplus is to be devoted to local improvements, "or in reduction of the capital moneys borrowed for electricity purposes." These Orders will not come into operation until they have been confirmed by Parliament.

Law Cases.

IMPORTANT PROSECUTION UNDER THE FACTORY ACT.

AT Worship-street Police-court Messrs. Bryant and May, Limited, were summoned before Mr. Corser by Mr. Vaughan, an Inspector of Factories, as the occupiers of a factory in which a contravention had occurred of a special Rule (VI.) made under the Act, the said factory being established for the manufacture of lucifer matches. Two other summonses complained that notice of a case of phosphorous poisoning to a woman named Hawkins had not been given to the Inspector and to the certifying surgeon of the district respectively.

Mr. Gilbert Bartholomew, managing director of the company, appeared to the summonses, and said he pleaded guilty.

Mr. Vaughan stated that the summonses were in respect of a woman named Caroline Hawkins, the Act of 1891 requiring that notice should be given of any symptoms of necrosis or swelling of the jaw occurring in any factory for the manufacture of lucifer matches to the Medical Officer of Health, as certifying surgeon, and the Act of 1895 required that on the presence of any certified disease of the kind notice should be given to an Inspector under the Act. For the breach of those requirements the company was summoned.

Mr. CORSER said he should not impose a fine for both offences in one case, otherwise a defendant might be fined on every section for one case.

Mr. Vaughan agreed, but pointed out that there were two offences, though there was only a slight distinction. He then said that though the summonses were taken only in respect of Caroline Hawkins, it was only one of a long series of cases which had been deliberately suppressed by the firm. He used the term with its full meaning, because the factory had been under his inspection, and that of other Inspectors for years, and from time to time denials of any cases of necrosis were constant. Then a man died, and an inquest disclosed the cause of death, and then the fact was admitted, and when further inquiry revealed that there were other cases the firm made a clean breast of it, and a long list of persons suffering and under treatment by the Medical Officer of the works was handed to him (Mr. Vaughan). There were eleven cases in all, but in consequence of the overt acts of the firm, the deliberate suppression of the facts, the Inspectors of Factories were led to believe that the special rules for the control of the factory and the notification of the disease were working satisfactorily. The reason the other cases he had referred to were not proceeded upon, was that the prosecution was limited by the Summary Jurisdiction Act to offences within the preceding six months. Had they been reported as required, some fortification of the special rules might have been made. He felt that this was a serious charge against Messrs. Bryant and May, as the firm was well known and extensive. But having regard to the number of cases and their suppression, he felt that he ought not to minimise the matter at all. In conclusion, he pointed out that the breach of the special rules carried a penalty of £10, and the neglect to give notice, £5.

Mr. Bartholomew said he could say nothing in

answer to the statement, and was sorry the offences had been committed. He wished, however, to point out that only one of the cases to which reference had been made had occurred since the special rules were passed, and that that ended in death before the diagnosis.

Mr. CORSER said that he agreed that it was a serious case, and having heard the facts he felt that a penalty should be imposed in respect of each default. He imposed the full penalty, £10, with £5 5s. costs, for the neglect under the special rules, and fines of £5 and 2s. costs on each of the other two summonses.

THE DRAINAGE OF COBHAM.

A CASE of some importance came before the Surrey county bench on Thursday of last week. The Epsom Rural District Council was summoned by the Thames Conservators for neglecting to abate a nuisance caused by the outfall of sewage from Cobham into the river Mole, a tributary of the Thames; notice of the nuisance and an order for its abatement having previously been served.

Mr. Bunting represented the Thames Conservancy Board, and Mr. Barnard Lailey appeared for the defendant Council.

Mr. BUNTING said that the summons was fully heard in June of last year, and the case was adjourned to give the defendants an opportunity of remedying the evils complained of.

Mr. BARNARD LAILEY said he would prove to the satisfaction of the Bench, and he thought also of the Conservators, that as much had been done by the Council in the time at their disposal as was possible to remedy the nuisance, and to provide an efficient scheme of drainage for Cobham, whereby the nuisance occasioned by the outfall of sewage into the river Mole would be mitigated. In addition to that the Council had set about borrowing a large sum of money to obtain possession of the land, until which time the scheme could not be carried out. The Council was prepared to pay any reasonable amount for the land, but the amount asked had been so greatly in excess of their surveyors' estimates that the Council had felt bound to refuse the offer. It was therefore necessary for the acquisition of the land to obtain compulsory powers. With regard to the loan which it was proposed to borrow, the Local Government Board had received the application of the Council, and the Council was now powerless to act, as the loan would not be granted before possession of the land had been gained.

Mr. W. O. Reader, solicitor, of Epsom, and Clerk to the Rural District Council, bore out counsel's statement as to the action of the Council. It had not been found possible to acquire the land by agreement with the landlord; and, until the land had been obtained, the Local Government Board would refuse to grant a loan of £22,000. As soon as the land could be obtained, the work would be commenced forthwith, as all plans had been prepared and approved. The Council had done all in its power to bring about the abatement of the nuisance. The Council's Sanitary Inspectors had been instructed to use their best endeavours to secure a mitigation of the nuisance, pending the carrying out of the large scheme.

The CHAIRMAN said the Bench were of opinion that such steps as could have been taken had been taken with regard to the acquisition of the land.

In cross-examination, Mr. Reader said he did not think it was necessary to send the detailed plans and sections to the Local Government Board before the matter could be taken further. Witness had seen one of the heads of the Local Government Board, and he had told witness that everything had been done by the Council towards securing the loan of £22,000 for the work.

Mr. Kiel, Sanitary Inspector to the Epsom Rural District Council, said he had a general order from the Council to do all he could to mitigate the nuisance, and had made frequent visits to the point of the outflow of the sewer, which was regularly cleaned out, and the general state of things was much better. There was no black, decomposed refuse as on the previous occasion.

Cross-examined: The Council had not spent any money in purifying the sewage, but the pits had been regularly cleaned out, and it was the matter in the pits that had been complained of by the Conservators.

The Bench considered it was very right and proper that the Conservators had brought the matter forward, and it had been shown that the improvement had been considerable. The summons would be again adjourned, and it was to be hoped that some definite steps would soon be taken in the matter.

Mr. LAILEY said the decision of the Bench would receive the close and immediate attention of the Epsom Council.

Notes and Queries.

[Subscribers have the privilege of obtaining advice in this column on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed to THE EDITOR, "Notes and Queries," THE SANITARY RECORD, 5, Fetter-lane, London, E.C.

NOTE.—If an answer be required immediately, a stamped addressed envelope must be enclosed, when we will endeavour to furnish a copy of the answer by post, as owing to the large number of queries received we cannot guarantee the insertion of a reply in the succeeding issue.

1106.—DRAIN AIR-INLET VALVE: MAKERS OF.—"Inspector, L.G.B." writes:—"In your Supplement to THE SANITARY RECORD of January 15th, 1897, on page 5, you illustrate and describe Mr. F. J. Simmon's patent drain air-inlet valve. I have tried, but failed to obtain the address of this firm. As I have some urgent work in hand I shall be grateful if you can supply me with the address of this firm."

Answer.—The name and address of the firm in question is Messrs. Alex. Wright and Co., 34—40, Millbank-street, London, S.W.

1107.—WELL SINKING: POLLUTION.—"Q. H. E." writes:—"I have just finished sinking a well, which is about 14ft. deep, passing through 3ft. of earth, 6ft. gravel, 5ft. clay, and 1ft. 6in. of grey soft sandstone, the water being drawn from the latter. I now find that the water is unfit for drinking purposes. Every possible care was taken in construction to exclude possible pollution, the steining down to the clay being formed of 9in. radiating bricks, backed with a coat of cement and 9in. clay puddle outside, so that no local contamination can possibly affect the supply. What can be done in such a case? Would it be got over by sinking the well lower, and ignoring the existing supply—that is to say, keep it out of the well, and tap another water-bearing stratum lower down?

Does it necessarily follow that I should find water by going lower? Or, if this course of sinking deeper, is no good, can you advise me the best course to pursue? I may mention that the analysis states that the contamination probably arises from drainage or cultivated land. I enclose section of well."

Answer.—Without a fuller knowledge of the local circumstances, it is somewhat difficult to advise. Has the querist ascertained whether there are any sources of pollution, such as leaking drains or cesspools, closely adjacent to the well, and which may be removed? Or is the land around the well manured, and so liable to pollute the supply? The section submitted shows that an impervious formation of clay has been passed through in order to reach the water-bearing stratum. Is the bed of clay thus shown continuous and impermeable or otherwise? If the latter, it may be difficult to avoid pollution unless the efficiency of the well is increased by sinking deeper, or tubes are driven through the underlying bed of clay into the next lower water-bearing stratum, if such be known to exist at a reasonable depth. On this point, in the absence of local knowledge, we should advise that a geologist of repute be consulted—one connected with H.M. Geological Survey is generally to be preferred. It might be prudent to obtain another analysis of the water before proceeding further. Our correspondent might usefully procure Swindell and Burnell's "Wells and Well Sinking," price 2s., obtainable from the Sanitary Publishing Company, 5, Fetter-lane, London, E.C.

1108.—Smoke Test Machines: Makers of.—"G. F. C." writes:—"I should be pleased if you will let me know names of the makers of smoke test machines. I should prefer one with a fan."

Answer.—The following firms manufacture smoke testing machines for drains, viz.:—Messrs. Burn Brothers, 23 and 24 Charing-cross, London, S.W., makers of the "Eclipse" tester; Messrs. John Watts and Co., Broad Weir Works, Bristol, makers of the "Asphyxiator" tester; Messrs. Baird, Thompson, and Co., 165, Queen Victoria-street, London, E.C., makers of the "Grahtryx" machine; Mr. John Barron, Great Northern Goods Depôt, Farringdon-street, London, E.C.; Mr. John Jones, 40, Sydney-street, Chelsea, S.W.; Messrs. J. G. Kirtley and Co., St. Thomas-street Works, Sunderland; Messrs. John Phillips and Co., 17, Anderston-quay, Glasgow.

1109.—Cement-testing Machines: Makers of.—"G. R." writes:—"Would it be convenient for you to inform me (1) where I could procure a good cement-testing apparatus; and also (2) mention the best publication treating of cements, limes, &c.?"

Answer.—Manufacturers of cement-testing machines are (1) Messrs. George Salter and Co., West Bromwich, makers of Kuhlmann's improved cement-tester; and (2) Messrs. Bowes, Scott, and Western, Limited, London, makers of Faija's cement-testing plant; (3) Heath's "Manual of Lime and Cement; their Treatment and Use in Construction," price 6s.; Gillmore's "Practical Treatise on Limes, Hydraulic Cements, and Mortar," 11th edition, price 18s., may be recommended. There is also the important series of articles on "Limes, Cements, and Mortars: their Composition and Analyses," by Mr. W. J. Dibdin, F.I.C., now appearing in The Sanitary Record, and which is intended to be published separately, which should not be overlooked.

1110.—Proto-Sulphate of Iron for Precipitation of Sewage: How Obtainable.—"J. W. W." writes:—"I wish to ask you if you could give me the address of some firms where I can get proto-sulphate of iron? I have Mr. Dibdin's book on "The Purification of Sewage and Water," and he speaks so highly of it that I have to try it."

Answer.—Proto-sulphate of iron may be obtained for precipitation of sewage from Messrs. T. Herschell, Jones, and Co., Swansea. This firm are mineral importers and chemical merchants, and can be well recommended. The price of proto-sulphate of iron is about 30s. per ton delivered.

1111.—Sewer Construction: Storm Overflow.—"E. T." writes:—"(1) Will the Local Government Board sanction an improvement scheme for street, where sewer is shown only 5ft. below surface, and not below cellar floor of adjacent houses? (2) What is the limit of storm overflows for sewers sanctioned by the Local Government Board, and how are they calculated?"

Answer.—(1) Our correspondent should have explained more clearly what he intended to be conveyed by an improvement scheme. Is the sewer in existence at present, or only proposed? If the latter, the Local Government Board might require the Local Authority—if a representation were made to them by any of the adjacent owners at the Local Government inquiry as to the insufficiency of depth of the proposed new sewer to receive the drainage from their cellars—to lay the sewer at such a depth as would be adequate to receive cellar drainage. It is possible, however, that the sewer cannot be laid lower, so as to be connected to the sewerage system; and if this be the case, the Local Government Board would not enforce a departure from the plans. (2) We do not know of any fixed limit as to the height of sills for storm overflows, nor for the proportion which storm water must bear to the sewage before the storm overflow can be put into action; nor is it likely that such a limit will be fixed, as so much depends upon the impurity of the sewage and the standard of purity which must be attained as required by Rivers Conservancy Boards before it may be turned into streams. In some cases sewage is so weak that if it is diluted with rain water to four times its own bulk it would be safe to pass it; while in other cases it may require dilution to ten times its bulk.

1112.—Sewerage: Velocity of Sewage: Ventilation.—"E. G. T." writes:—"(1) In calculating the quantity of flow of sewage into a settling tank, would it be enough to take the last length nearest to the tank for the velocity and discharge in a sewer having varying gradients, or would the other different gradients have a bearing upon it? (2) In making a sewer which falls both ways from the highest part of a street, would it be right to make the ventilator act for both lengths of the same?"

Answer.—If the section of sewer nearest the settling tank be of some considerable length, the velocity and discharge must be calculated from this section, especially if it be of a less gradient than those sections above. Where, however, the last length is short, the velocity and discharge will be influenced by any greater gradients which may exist above it. (2) From the sketch submitted by our correspondent, it appears that the street wherein the proposed sewers are to be laid falls from the middle of its length in two directions, and that the sewers are intended to discharge at opposite ends of the street, but that they will be joined together at a manhole in the highest part of the street. If a ventilating shaft be connected to this manhole, the shaft will serve the purpose of ventilating both sections of sewers.

1113.—Ditches Alongside Public Highways: Cleansing of.—"E. H. B." writes:—"What legal right has a Highway Authority in any part of England to make the owners or tenants—farmers of adjoining lands—clean out the ditches by the side of the highways? I am aware that the theory is that the ditches belong to the owner or occupier of the land on the other side of the hedge; but this seems to me to apply to field hedges and ditches, which are, of course, to the interest of the occupier to clean out. In the case of roads the public benefit at the expense of the owner or tenant, and

it always appears to me that if either of them refused to clean out the ditch, there is no power to compel them."

Answer.—It has been laid down by the law officers of the Crown that "at common law a duty exists on the part of the owner of lands adjoining a highway to cleanse and scour his own ditches to such an extent as to prevent nuisances or obstruction to passengers, but that this duty can only be enforced by indictment. The general practice with Highway Authorities is to cleanse the ditches, as they are enabled to do under Sec. 67 of the Highway Act, 1835, and charge the cost on the highway rate. The effect of Sec. 67, as referred to, is to empower the Surveyor or Highway Board to cleanse ditches in a more effectual manner than landowners could be compelled to cleanse them.

1114.—Expanded Metal for Use in Concrete.—"A. T. B." writes:—"I beg to thank you for your reply to my query, No. 1105, on 'Concrete Bridges.' Would you please give me the address of a firm who make wrought iron wove netting, suitable for use with concrete structures, such as bridges, &c.?"

Answer.—For use with concrete floors, bridges, &c., the new expanded metal manufactured by the Expanded Metal Company, Limited, 39, Upper Thames-street, London, E.C., is difficult to be excelled. This material can be obtained in meshes varying from $\frac{3}{8}$in. to 6in. wide, and in thickness from 24 B.W.G. to $\frac{3}{16}$in. in steel, brass, or aluminium.

1115.—Cesspool Vans: Makers of.—"F." writes:—"Can you oblige by informing me of the name of the maker of a good type of tank cart, detachable force pump and stand, with hose, suction and delivery complete, suitable for the emptying of underground sewage tanks or cesspools?"

Answer.—Cesspool vans, for the removal of contents of cesspools, are manufactured by the following firms:—William Glover and Sons, Limited, Eagle Works, Warwick; Bristol Wagon and Carriage Works Company, Limited, Bristol; Woods and Co., Stowmarket, Suffolk; George Waller and Co., 165, Queen Victoria-street, London, E.C. The last-named firm make a speciality of pumps, and we can speak with confidence of their lift and force cesspool pump, mounted on wheels. Messrs. Glover and Sons are makers of the patent Radstock cesspool emptier, which is a cesspool van or cylinder designed to empty cesspools automatically, the principle of which is that the cylinder is filled by pneumatic agency. By means of a rotary air pump, worked by the rotation of the wheels when the van or cylinder is travelling, a vacuum is created in the cylinder; on arrival near the cesspool, the cylinder is connected by the suction pipe, and on a valve being opened the contents of the cesspool rush into the cylinder, when on being filled it is removed for emptying, the process being repeated on the next journey.

1116.—Sanitary Institute Examinations.—"J. W. D." writes:—"Would you be so kind as to tell me what Acts of Parliament, orders, and regulations I would require to get up to enable me to pass the examination of the Sanitary Institute, and where I could procure same?"

Answer.—Our correspondent should refer to our reply to Query 1034, in our issue of April 15th last, wherein we gave a list of books to be studied for the Inspectors' examination of the Sanitary Institute. We have previously advised, and continue to advise that candidates for these examinations will generally enhance their chances of success by studying under the guidance of an experienced "coach," several of whom advertise in our pages. Reid's "Practical Sanitation" (6s.) and Davies and Yabbicom's "Notes on the Factory and Workshop Acts," 4d., contain all the law necessary to be learnt by students.

1117.—Reduction of Salaries of Inspectors of Nuisances when off Duty through Sickness.—"L. S. D." writes:—"The Urban District Council of K— has recently adopted a resolution to pay their Sanitary Inspectors, who are appointed at a yearly salary, a very much reduced rate during sickness. There are no terms in their original engagements as to reduced salary during sickness, and they have hitherto received full pay when off duty through sickness. Can the Council legally stop part of the salaries under such circumstances? Please state any case bearing on the question. The resolution of the Council appointing the officer is in the following terms:—'Resolved that —— be, and is hereby appointed an assistant inspector at a salary of ——; that he devotes the whole of his time to the service of the Corporation, and that this appointment be terminable by one month's notice on either side.'"

Answer.—The power of Urban Authorities to appoint an Inspector of Nuisances and assistants is conferred by Sec. 189 of the Public Health Act, 1875. In the case of Inspectors, part of whose salaries is repayable by the County Council, under Sec. 243 of the Local Government Act, 1888, the appointment is subject to the approval of the Local Government Board. We are not informed whether the Inspector's appointment in the case put to us was subject to this approval. In any case, we are of opinion that the Local Authority cannot, in the appointment of an Inspector of Nuisances, make any deduction from his salary on account of illness, and he would be able to recover the amount of any deduction in any court of law. If the Inspector's appointment has been confirmed by the Local Government Board, we should advise him to communicate with that Board on the subject.

Contracts Open.

The dates given below are the latest up to which tenders can be received.

Bury St. Edmunds.—June 13th.—Plant.—Mr. F. Hastings Medhurst, B.Sc., M.I.E.E., consulting engineer to the Corporation, Westminster-chambers, 13, Victoria-street, S.W.

City Engineer (Cape Town, June 15th).—For the Corporation of the City of Cape Town. Commencing salary £800 per annum. Messrs. Davis and Soper, 54, St. Mary-axe, London, E.C.

Walton (Wakefield).—June 13th.—Sewering and Road-making.—Mr. William Watson, architect, Barstow-square, Wakefield.

Blackburn.—June 13th.—Reconstructing Privies, &c.—Mr. William Stubbs, A.M.I.C.E., borough and water engineer, Municipal-offices, Blackburn.

Rochdale.—June 15th.—Sewers.—Mr. S. S. Platt, M.I.C.E., borough surveyor, Town Hall.

Newark.—June 16th.—Lighting.—Mr. F. B. Foottit, secretary, Newark.

Poole.—June 16th.—Drain.—Mr. John Elford, borough surveyor, King-street, Poole.

Stonehaven (Scotland).—June 18th.—Sewer.—Mr. Murdoch, burgh surveyor, Stonehaven.

Totnes.—June 20th.—Sewage Works.—Mr. W. F. Tollitt, borough surveyor, Gate House, Totnes.

Hale (Cheshire).—June 21st.—Sewers.—Mr. J. M'D. M'Kenzie, 7, Market-street, Altrincham.

Southampton.—June 14th.—Sewerage Works.—Mr. W. B. G. Bennet, borough engineer.

To Medical Officers, Surveyors, Sanitary Inspectors, &c.—High-grade Cycles at reasonable prices for prompt cash and on the GRADUAL PAYMENT SYSTEM. Catalogue post free.—MELROSE CYCLE COMPANY, Coventry.

Vacancies.

BUILDING INSPECTOR (MERTHYR TYDFIL, June 13th).—For the Urban District Council. Salary, £2 2s. per week. Mr. John Vaughan, clerk, public offices, Merthyr.

CLERK OF WORKS (BERKHAMPSTEAD, June 16th).—For the Joint Committee for the Berkhampstead and Northchurch sewerage. Salary, £3 3s. per week. Mr. Samuel Stallon, clerk, Hemel Hempstead.

CLERK OF WORKS (ROCHESTER, June 15th).—Salary, £3 per week. City Surveyor, Rochester.

CLERK OF WORKS (ROTHERHAM, June 11th).—For the Board of Guardians. Salary, £3 per week. Mr. G. T. Barras, clerk, Rotherham.

CLERK OF WORKS (Surbiton, June 11th).—For the Urban District Council. Salary, £3 per week. Mr. Samuel Mather, A.M.I.C.E., district surveyor, Surbiton.

CLERK OF WORKS (WIMBLEDON, June 13th).—For the Urban District Council. The salary will be £3 3s. per week. Mr. W. H. Whitfield, clerk, Council Offices, Broadway, Wimbledon.

ENGINEER (LIVERPOOL, June 15th).—Mr. James Moulding, clerk, 15, High Park-street, Liverpool.

INSPECTOR OF WEIGHTS AND MEASURES (DEVONPORT, June 15th).—For the Town Council. Salary, £75 per annum. Mr. A. B. Pilling, town clerk, Devonport.

SANITARY INSPECTOR (LONDON, E.C., June 14th).—For the Corporation of London. Salary, £140 a year, with annual increments of £5 to a maximum of £200 per annum, with uniforms. Town Clerk, Public Health Department, Guildhall.

SURVEYOR (CONSETT, June 15th).—For the Urban District Council. Salary, £180 per annum. Mr. Thos. Wm. Welford, solicitor, clerk, Consett.

COMPETITIONS.

LINSDALE, July 1st.—Sewage Disposal and Water Supply. — The Linsdale Urban Council invite plans, specifications, with estimates for dealing with the sewage disposal and water supply for the above-named district, such plans and estimates to be sent to Mr. R. I. Platten, clerk, Linsdale, Leighton Buzzard, by July 1st, marked with a motto or *nom de plume*, and endorsed "Linsdale Sewerage and Water Supply."

FORMBY (LANCS), July 1st.—Sewerage Scheme.—The Formby Parochial Committee invite competitive schemes for the sewerage of a portion of the township of Formby. Premiums are offered amounting to £100 for the scheme considered first in order of merit, £50 for the second, and £25 for the third. Mr. J. H. Havelock Suttor, Piercefield-road, Formby. A professional assessor will be appointed to adjudicate upon the plans.

INSURANCE.

THE MUTUAL LIFE INSURANCE COMPANY OF NEW YORK.

PRESIDENT:
RICHARD A. McCURDY.

Policy-holders in the "Mutual" enjoy the advantages of

SECURITY—
Assets, 1897.. .. exceed £52,000,000
Surplus .. .. .. exceeds 7,250,000

ADAPTABILITY—
LIFE INSURANCE.
INVESTMENT.
INCOME.

PROMPTITUDE—
Claims paid in London immediately on receipt of satisfactory proofs.

LIBERALITY—
Bonuses have, in many cases, trebled the original sum.
Surrender values of unique liberality paid.

Detailed information supplied on application.

Head Office for the United Kingdom—
17 and 18, CORNHILL, LONDON, E.C.
D. C. HALDEMAN, General Manager.

TO OUR READERS.

The Editor solicits the co-operation of readers in making THE SANITARY RECORD *more attractive by means of pen-and-ink sketches, photographs, and diagrams. There are many phases of sanitary work which lend themselves admirably to illustration. By this means not only individual articles, but the journal as a whole will be brightened.*

CAMPHYLENE CREAM

(unlike most Fluid Disinfectants) possesses a most refreshing and agreeable odour, yet thoroughly effective.

Unequalled for use in Hotels, Clubs, Public Conveniences, for Flushing Drains, Sewers, &c. &c. Supplied to a large number of Corporations, County Councils, and other bodies throughout the United Kingdom. 3s. 6d. per Gall. in 5 or 10 Gallon drums. Samples and special quotations for quantities on application.

PRACTICAL Smoke Prevention.

By W. NICHOLSON,
Smoke Inspector, Sheffield.

This little booklet, from a practical pen, deals in a comprehensive and capable way with a problem in which most of our big towns and cities are concerned. Its reasonable price should enable it to be distributed wholesale in quarters where the lessons it inculcates would be appreciated, and so distributed, it cannot fail to be productive of much good.

PRESS OPINION.

"A very useful little book, which will be found very instructive to engineers and all having care of steam boilers."—*Liverpool Daily Post.*

Notes.

Legislative Prospects.

NOW that Parliament has once more resumed its labours, it is appropriate and fitting that we should make a brief forecast of what we may expect from the session that has just commenced. The Government are in the fortunate position of having already cleared off most of the larger measures which they placed in the forefront of their legislative programme; so that, with their enormous majority, there is no reason in the world why the larger number of their minor Bills should not be placed on the Statute Book before the prorogation. We are not sure, however, that we are entitled to make this assumption, from the outline which Mr. Balfour gave the House of Commons of the business with which he intends to proceed. A studious reticence was maintained on the subject of the Food and Drugs Adulteration Bill, and it is still uncertain what are the Government's intentions with regard to that measure. As to the Aliens' Bill, which affects so deeply the question of overcrowding in the East End of London, Mr. Balfour would give no assurance, as it is not a Government Bill. The Vaccination Bill and the Prisons Bill are, however, well advanced by this time, and we may reasonably look for their being passed into law.

The Dangers of the Match Trade.

THE Home Secretary was also subjected to an important series of questions arising out of the Bryant and May prosecution, which we noticed last week. The whole subject of the dangers incident to the use of phosphorus in the match trade is one for the serious consideration of the Home-office, and it is reassuring to know that Sir Matthew Ridley is fully alive to the necessity for an improvement in the law such as will prevent a repetition of the lamentable occurrences in Bryant and May's factory. We welcome with satisfaction his assurance that the responsibility for those occurrences in no way attaches to the certifying surgeon. The fatal neglect of duty lies at the door of the works doctor, and we expect that we shall hear soon of some further action—possibly penal—being taken with regard to his conduct. On the general question of the protection of the operatives in match factories, it is evident that we have something to learn from our continental neighbours regarding the restrictions in the use of phosphorus in the manufacture, and the Home-office has undertaken to inquire into the restrictions that are observed in France and elsewhere abroad. It would also appear that the danger of phosphorous poisoning may be obviated to a certain extent by the adoption of machinery capable of making lucifer matches without the close proximity of the workers, coupled with an improved system of ventilation. There is obviously a large field for inquiry, and the sooner it is undertaken the better. The special rules will have to be strengthened, and the medical supervision improved; and if these reforms are speedily effected, the Bryant and May case will not have been without its good results.

The Sale of Poisons.

A BILL, promoted by the Pharmaceutical Society, and having for its chief object an amendment of the constitution of the Society, is at present before Parliament; and an attempt has been made to make it the occasion for a removal of the restrictions on the sale of poisons. The desire for greater liberty was conceived in the interests of perfectly legitimate trade, and was no doubt very natural. Many manufacturers who supply farmers with insecticides or preparations for destroying vermin or disease in plants find the Pharmacy Acts a serious impediment. But we are glad that the House of Commons was in no mood to favour a relaxation of the law. We have just had, in the St. Neots murder case, a very glaring illustration of the dangers of laxity in the law relating to the sale of poisons; and sensible men are asking themselves, not whether the existing regulations should be relaxed, but whether they should not be made much more stringent.

Lead Poisoning in the Potteries.

As we anticipated in our recent remarks on this subject, the question of the appointment of Lady Inspectors for the Potteries district has been brought up in the House of Commons, and not only this question, but also the whole question of how the interests of the workers in the unhealthy and dangerous pottery industry may be most effectually safeguarded. Mr. Hedderwick asked the Home Secretary whether he would appoint a Lady Inspector for the protection of the workers, who are mostly women and children; and, further, whether he would altogether prohibit the use of lead in glazing processes in potteries, or bring such processes within the scope of the Workmen's Compensation Act. There were thus three distinct issues raised. As to the first of these, the Home Secretary contended that the existing staff of Lady Inspectors had done most useful work in the Potteries district, and he hoped would continue to do so in the future; and he even went so far as to express his cordial appreciation of the value of inspection by women in this industry, and to indicate that he was, in fact, considering the desirability of increasing the staff, though he would give no definite assurance on the point. That, it will be noted, is a considerable concession on his previous attitude, which it is gratifying to observe. The most urgent question, however, in the view of the Home-office, relates to the appointment of a Medical Inspector. It is at present under consideration, and upon the issue of that question will largely depend the decision of the department as to an increase in the number of Lady Inspectors.

A Promise of Reform.

THE second issue, as to the total prohibition of lead in glazing processes is one that Sir Matthew White Ridley declared he had no power to deal with. He can regulate and control dangerous processes by special rules under the Factory Acts, but the Acts do not extend this power to one of prohibition. The Home-office believes, however, that certain reforms in the direction of diminishing the use of dangerous glazes are practically possible. What these may be will entirely depend on the report to be made by the experts who have been appointed to inquire into the subject. Inquiries are also being made into the methods in vogue in foreign manufactures, which are expected to afford us additional light for our guidance. The third question raised by Mr. Hedderwick, involving the extension of the Workmen's Compensation Act to pottery employés, cannot be dealt with except by fresh legislation, which the Home Secretary says he is not in the meantime prepared to initiate. But if he is right in his belief that the new special rules will materially diminish the dangers to which the workpeople are exposed, we shall have much cause to be thankful for a greatly needed reform.

The Accumulation of Evidence.

ANOTHER fatality was reported in the Potteries last week. A young woman, aged 27, had to cease work some six months ago, and was laid up for five weeks. A few days since she resumed work, but soon complained of pains in the head. An epileptic fit followed, and, after terrible suffering, she died. At the inquest it was proved that the cause of all this agony was lead poisoning. On Monday last a letter appeared in the *Times* from Mr. Sydney Holland, the highly-esteemed chairman of the London Hospital. It appears that three victims have been removed from the Potteries to London in the hopes that something might be done for them. It is after a visit to these that Mr. Holland pens his letter. We can only give a few words:—"I have just left a poor woman sitting quietly and patiently, resigned to her terrible fate, blinded for life by lead poisoning. By her side sat another girl, nearly blinded by the same foul poison, but whose sight we hope to save. In another ward is a poor man suffering from epileptic fits due to the same cause, and the story they tell would simply not be believed if they did not bear on themselves the truth of their statement. I met a man visiting these poor patients, who has just returned from the Potteries, upon whose testimony I can rely. I will quote him and not them, lest it should be suspected that their evidence is prejudiced—little wonder if it was. He tells me that fourteen cases of blindness have lately come to light, some of them partial, but the majority total and incurable; that the lead poisoning is admitted by the authorities to be increasing, and that the cases reported from the Potteries number some hundreds every year; that the methods of production pursued in the Potteries are guided, not by science—there is not, he tells me, on the authority of a manufacturer, a single consulting chemist in the Potteries—but by rule of thumb." This latter statement is simply astounding, for such a thing is directly opposed to the employers' own interests. But the case for special Inspectors—male and female—is proved over and over again. Will the Home Secretary still hesitate to act?

The Exeter Sewage Scheme.

WE draw the special attention of our readers to the announcement made on another page to the effect that the Local Government Board has given its consent to the proposed sewerage scheme for Exeter. It is well known that the decision of the Board was awaited with some anxiety, for the scheme propounded possesses many features of novelty, which are regarded by some as purely experimental. This also appears to have been the feeling at headquarters, for the "approval" is given on the understanding that many "safeguards" are introduced in case of failure. We do not think any complaint can be made against such action; for there is no doubt several places have had to pay dearly for ill-advised experiments in days gone by. The engineer, Mr. Cameron, is very confident of success, and he claims that the results obtained on a small scale warrant his belief. The most notable feature, however, is the fact that the decision of the Board shows that it is fully alive to the advances made in the scientific treatment of sewage, and other districts will be encouraged to avail themselves of newer and better methods than those at present employed.

The Royal Institute of Public Health.

IN our issue of June 3rd we gave a brief outline of the arrangements made for the Annual Congress of this Institute, which opens in Dublin on August 18th. We are now able to give further details of

the suggested proceedings in the Sanitary Inspectors' section under the presidency of Mr. Conway Scott, C.E., Belfast. Inspectors and others are invited to contribute short papers for discussion upon the following important subjects: — (1) The relative responsibility of landlord and tenant for sanitary improvement and abatement of nuisances, and the amendment of the laws relating thereto. (2) Sewers and drains—amendment of laws relative to, &c. (3) Education and examination of candidates for the office of Sanitary Inspector. Practical papers bearing upon these subjects should elicit interesting critical discussion, and so draw out valuable suggestions. In consequence of the considerable advances made in sanitary legislation and the growing necessity for meeting the requirements of domestic and public hygiene, it becomes a matter of vital importance that sanitarians and all others interested in the welfare of public health should be afforded the opportunity of assembling and exchanging views and suggestions at meetings such as the above Congress affords. In addition to the papers to be read, and the discussions upon same, it is proposed that inspection shall be made of the principal buildings in connection with the Public Health Department of the Corporation and their workings explained to the delegates. Large public works and institutions throughout the city will also be visited. These inspections are additional to those previously announced.

Workmen's Compensation for Accident.

It will be well for Local Authorities to realise that we are on the eve of a complete revolution in the conditions of employment. The new Workmen's Compensation Act, which comes into force on the 1st of next month, is causing considerable anxiety among ordinary manufacturing firms, and preparations are being made for meeting the increased liability imposed upon them. But many of our public bodies do not appear to understand that they, too, are included within the scope of the Act, and that their responsibility is just as great as that of an ordinary employer. What the extent of that responsibility is, it is impossible to estimate. One who took a prominent part in framing the measure puts it at just about double what it would be under the old Employers' Liability Act, in other words, where an annual premium of £2 10s. was sufficient to secure them against loss, all that should now be necessary is one of £5 at the outside. But the insurance companies think otherwise, and we hear of premiums twenty times as large as those formerly demanded. Thus we have a wide divergence of opinion. One thing, however, is clear, it is extremely unwise for the various Councils to ignore the new *régime*. They should either establish a private fund, or effect insurances in some of the best offices. Anyhow, the matter is one of urgency, and should receive the attention of Councils and Vestries without delay.

The Itinerant's Ice Cream.

Something is likely to come from the action of the St. Olave's district in calling the attention of the Local Government Board to the dangers arising from the sale of "ice cream" by street vendors. The circumstance has been noted in a large number of metropolitan and provincial papers, and the *St. James's Gazette* sent forth a "special" to make inquiries. The Clerk of St. Saviour's was visited; Dr. Harris, the Medical Officer of Health for Islington, interviewed; and the report of Dr. Klein consulted, with the result that on Monday last our contemporary was able to issue the most telling contents bill of the day. We pass over the the details concerning "millions of microbes," or the analyses of Dr. Klein showing colonies of "billions of bacilli"—not "inferior to that obtained from sewage." We are afraid the boys of the street will not see the doctor's report, or, even if they did, they would but slightly realise the danger they run in consuming such concoctions as the itinerant vendor supplies. The most important point brought out by the special correspondent is Dr. Harris's remark that there is no standard for ice-cream, and none can say of what it should legally consist; and there is nothing in the Public Health Act whereby the sale can be prevented or the manufacture controlled. A short Bill in Parliament, however, might remedy this, and Local Authorities should be empowered to compel the registration of vendors, and make bye-laws regulating the conditions under which ices can be made and sold.

The National Health Society.

The large company assembled on Saturday last at Grosvenor House demonstrated the interest evinced in this Society. Very quietly it does its work, but the nation owes much of the improved hygienic condition to its operations during the twenty-one years the Duke of Westminster has presided over its fortunes. This fact was emphasised by Sir James Creighton when he stated that the gospel of cleanliness was being preached in all directions, in contradistinction to what was done fifty years ago. One notable effect is the marked decrease in consumption. In 1837 the proportionate death-rate was double what it is to-day; and one eminent authority has gone so far as to predict that thirty years hence this disease will be almost unknown. If this should prove correct, Sir James claimed that in no small degree would it be due to the efforts of the Society. The Princess Christian—ever ready to help a good cause—was present, and distributed diplomas, medals, and certificates to successful candidates.

Registration of Midwives.

The movement in favour of compulsory registration makes steady progress. At the annual meeting of the Association for securing this object, it was stated that as the result of letters sent out to the various coroners, asking permission to publish their names as being in favour of the objects of the Association, 153 out of 240 expressed themselves in accord with them, and only 15 were in any way opposed to the measure. People do not realise that almost any woman, however unskilled, can at present set up as midwife without being under the control of anyone, and that the only risk she runs is to receive censure from the coroner in any cases in which her inefficiency might have fatal consequences. Compulsory registration would alter this, and act as a "most salutary safeguard to the public."

THE CHEMICAL AND BIOLOGICAL ANALYSIS OF WATER.

By T. H. Pearmain and C. G. Moor, M.A. (Cantab).

Members of the Society of Public Analysts. Authors of "Applied Bacteriology," "The Analysis of Food and Drugs," &c.

(*Continued from page* 614.)

CHEMICAL EXAMINATION.

TOTAL SOLIDS.

The amount of solid matter left on the evaporation of a given quantity of water will naturally vary largely according to the geological character of the locality from which it has come. The "total solids" of a potable water consist mainly of calcium carbonate, sodium chloride, small quantities of nitrate, and sulphate of calcium, and a little silica, together with any non-volatile organic matters that may be present. The total solids in a good drinking water are generally not much above thirty grains per gallon.

If it is not desired to ascertain what the total solids consist of, but merely to learn their amount, it will be sufficient to work on 70 c.c., which should be evaporated in a platinum dish. The dish must be cleaned with pumice powder till quite bright outside and in, and the evaporation may be begun over a lamp, but must be finished over a water bath.

A temperature of 100 deg. Cent. is not sufficient to expel all moisture, and the dish should then be placed in an air bath and heated up to just 120 deg. Cent. for at least twenty minutes. It is then placed in a desiccator till just cold and weighed without delay. Not only do the "total solids" absorb moisture with great readiness, but the dish itself becomes heavier owing to the property possessed by platinum of occluding gases on its surface, so that a dish weighing 25 to 30 grammes may gain two milligrammes in standing in half an hour after heating. It is therefore essential that the dish should be weighed within a definite time, say, four minutes, after placing in the desiccator, whether it contain "total solids" or be weighed empty.

After the weight of the total solids has been obtained it is well to note carefully their behaviour when they are exposed to a very low red heat. If an appreciable quantity of organic matter is present when heat is applied, the solids will darken, and, on smelling, an odour of weeds or of burning animal matter may be perceived, according to whether vegetable or animal pollution is present, and in most polluted waters the smell produced is very distinctive. The temperature at which the ignition should be done is the lowest possible red heat, which must be continued just long enough to cause any darkening to give place to a white or grey, thus showing the complete combustion of the organic matter. By heating in this way we shall obviously expel carbonic acid from any carbonate of calcium that may be in the residue, and if the weight of the solids after ignition is subtracted from that of the total solids before ignition, the loss will be due to organic matter and to expelled carbonic acid. As it is our object to obtain as closely as possible the true weight of combustible matter, we replace the expelled carbonic acid by moistening every part of the residue with a strong solution of ammonium carbonate. After drying, the dish is very cautiously heated so as to expel all excess of ammonium carbonate, but not to causticise the calcium carbonate afresh. Although it is more than probable that the figures we obtain in this way are liable to considerable errors, the estimation is well worth making, for it will rarely happen that a good water, except possibly a peaty one, will yield a residue that will either darken or smell much on ignition, while there are very few bad waters that will not betray their character by the one or other indication. The "loss on ignition" in a water of good quality will seldom amount to more than 20 per cent. of the total solids. Generally speaking the total solids should not exceed 40 or 50 parts per 100,000, but, of course, much depends upon the constitution of the solids and upon the geological source of the water. Except in the case of waters from peaty sources, the slightest evidence of fumes, or darkening of the solids on ignition, will point to organic contamination.

ESTIMATION OF CHLORIDES.

Sodium chloride is a very constant constituent of urine, in which it is present to the extent of about 0·75 per cent., and hence is always to be found in waters that have suffered contamination from sewage or cesspool leakages.

The absence of chlorides in a water may be taken as good evidence of absence of sewage pollution, but the converse is, of course, not the case, as chlorides in water are also derived from the geological strata through which the water passes.

As chlorides are not readily removable from drinking water or sewage by any natural or artificial process, except, perhaps, by being drawn up by the roots of plants, it follows that when a water has suffered contamination with sewage matters the chlorides will remain as evidence, even after the organic matter that accompanied them has undergone natural purification and has disappeared.

Chlorine is usually estimated by titrating 70 c.c. of the sample, filtered, if necessary, with a standard solution of nitrate of silver. Decinormal solution of silver nitrate being rather too strong for convenience, it is customary to use a solution, so that every cubic centimetre of silver solution used up will indicate a grain of chlorine per gallon.

According to the equation,

$$AgNO_3 + Na\,Cl = AgCl' + NaNO_3,$$

and the molecular weight of silver nitrate being 170 and chlorine 35·5, one part of chlorine will be exactly precipitated by $\frac{170}{35·5}$ or 4·79 parts of silver nitrate, so that a solution, one cubic centimetre of which exactly precipitates a milligramme of chlorine, must contain 4·79 milligrammes of silver nitrate per cubic centimetre, or 4·79 grams per litre.

In preparing the solution nitrate of silver should be heated in the air-bath nearly up to the fusing point, and then 4·79 grammes weighed out quickly and dissolved in a litre of distilled water. The solution should be kept in a brown coloured bottle, or in the dark. The titration is performed in a white porcelain dish, and a drop of solution of potassium chromate is used as indicator. As soon as all the chlorides in the water have been converted into the silver salt any further addition of silver will cause the formation of silver chromate,

which is brick-red in colour, so that as soon as a perceptible colour is observable the titration is stopped, and the amount of silver solution used up is noted.

It is usual to deduct ·2 of a cubic centimetre for the amount of silver solution required to change the colour of the indicator.

W. G. Young has shown (*Analyst* 18, 125) that titrations to estimate chlorine should be performed always on cool solutions, as an increase of temperature even to 38 deg. Cent. (blood heat) gives results too high in consequence of the increased solubility of silver chromate with rise of temperature. He also shows that it is preferable to concentrate the solution to be titrated, and not to work with too dilute a solution of silver nitrate.

The amount of chlorine found in a water depends largely upon the nature of the soil through which the water has permeated. Surface waters and waters collected in the neighbourhood of the sea frequently contain very large quantities of salt, and in these cases the amount of chlorine found has but very little significance, but in cases where the geological strata contains but little chlorides, and where there are no manufacturing effluents to cause pollution, the amount of chlorides found is a very valuable guide to the approximate amount of sewage contamination present in the water. In several of the American States, particularly Massachusetts, the normal distribution of chlorine has been mapped out. This has been done by estimating the amount of chlorine in the unpolluted waters of the districts at a large number of points. When these points are joined by means of lines the normal distribution of chlorine at a particular point is easily found. These lines are known as *Isochlors*. From the chart so prepared of the "isochlors" in Massachusetts, the normal chlorine is found to vary from 0·45 grains per gallon near the coast, to less than 0·06 in the western part of the State ("Board of Health Report, 1892") These plans of the "isochlors" are exceedingly valuable, as when in a given spot an amount of chlorine is found in excess of the normal, it points to practically positive evidence of sewage pollution. It has been estimated by Thresh that each 100 persons per square mile add on the average 0·03 grains of chlorine per gallon to the water flowing from the area in consideration. From this data it is easy to calculate the approximate extent of the pollution. Unfortunately the plan of determination of the "isochlors" of districts, which is being so systematised in the United States, has but little application in small insular countries like England, although much valuable information might be gained by the systematic determination of the normal chlorine in the unpolluted waters of given areas. It should be noted that the value of the chlorine determination is largely detracted by the fact that the organic matter which originally accompanied the pollution may have become completely oxidised. Therefore it should be noted that the chlorine figure does not necessarily denote present pollution, although it may to a great extent be a measure of the past pollution, if it exceeds the normal chlorine figure of the district, which is due to geological conditions.

Generally speaking, unless it is accounted for by the geological conditions of the district, a greater amount than two parts per 100,000 should be regarded with suspicion.

HARDNESS OF WATER.

The hardness of water is generally due to the presence of salts of calcium and magnesium. It is measured by ascertaining how much of a standard soap solution is required to produce a lather lasting for two minutes with a certain volume of the water.

When a standard soap solution is run into a solution of a calcium salt till a lather is formed, in determining hardness in water, each equivalent of lime destroys an equivalent of soap. Put in an equational form in the case of calcium sulphate and sodium oleate,

$$CaSO_4 + 2NaC_{18}H_{33}O_2 = Ca(C_{18}H_{33}O_2)_2 + Na_2SO_4$$

A convenient quantity of water to take for the purpose is 70 c.c., and then if our soap solution contains just sufficient soap per cubic centimetre, to be exactly precipitated by a milligramme of chalk, it is clear that the number of cubic centimetres of soap precipitated by 70 c.c. of the sample of water will indicate the number of grains per gallon of chalk in the water, after allowance has been made for the amount of soap needed to produce a lather in pure water. It is clear that a certain amount of soap solution will be required to make a lather even in a water containing no hardness at all, and if the experiment be tried, using 70 c.c. of distilled water, it will be found that 1 c.c. of soap solution makes a lather lasting about two minutes. It is therefore customary to subtract 1 c.c. from the number of cubic centimetres of soap solution required to make a lather with distilled water. Soap solution is most easily prepared by dissolving 10 grammes of white Castile soap in fine shavings in methylated spirit. After warming, the soap will dissolve, but the solution will probably be cloudy, and must be filtered through filter paper. This solution has now to be tested against a water of known hardness, and, if too strong, some more spirit must be added, or, if too weak, some more soap. The soap solution will not keep at the same strength, but gradually becomes weaker, and it is therefore best to test it every time before it is used. For this purpose we require a solution of standard hardness, which is generally made by dissolving a gramme of Iceland spar—a pure form of calcium carbonate—in hydrochloric acid, evaporating to expel excess of hydrochloric acid, and making up to a litre with distilled water. Such a solution will then contain the equivalent of one milligramme of calcium carbonate in every cubic centimetre. We are obliged to dissolve the Iceland spar in an acid, because neither Iceland spar nor any other form of calcium carbonate is soluble to the extent of more than two grains per gallon. We have, therefore, to assume that the soap-destroying power of the calcium is the same when dissolved as calcium chloride, as it has in an ordinary drinking water, where it exists mainly in the form of calcium carbonate kept in solution by excess of carbonic acid gas. Supposing, then, that we are testing a fresh batch of soap solution, we should place the soap solution in a burette and take 10 c.c. of the solution of standard hardness, make it up to 70 c.c., and run in the soap, as in testing an ordinary water.

If the soap solution is just of the right strength a lather, lasting two minutes, should be produced by 11 c.c.

(To be continued).

THE MANCHESTER REPORT ON SYSTEMS OF SEWAGE PURIFICATION.

(Continued from page 590.)

SAMPLES of sewage and tank effluent were obtained by the Committee's Chemist, and the following is his report :—

Oldham Sewage Works,
January 12th.

Description of Samples.

The raw sewage contains grey suspended matter. It is chiefly of a domestic character. It occasionally contains a certain amount of cotton waste and oily matter from the cotton mills.

The tank effluent taken at 12 noon has a white opalescence ; is neutral to litmus.

The cinder filter sample has the same opalescent appearance, though to a less extent than the tank effluent. It is all neutral to litmus. It was taken shortly after noon.

Analytical Numbers

	Grains per Gallon.			
	Oxygen absorbed, four hours.	Free and saline ammonia.	Albuminoid ammonia.	Chlorine.
Raw sewage (shaken)	4·08	2·30	·70	—
Raw sewage (settled)	1·98	2·40	·38	4·5
Tank effluent	.98	1·10	·17	4·4
Effluent from cinder filter	·48	·85	·14	4·8

The chlorine figure shows the cinder filtrate to be from rather stronger sewage than the tank effluent. Reducing the two to a common chlorine standard, the albuminoid ammonia figure for the cinder filter becomes ·13.

Incubator Tests.—Three Minutes' Oxygen Absorption.

	Grains per Gallon. Before incubator.	After incubator.	Putrescibility.
Sewage (settled)	·58 ...	2·63 ...	Putrid in 2 days
Tank effluent ...	·36 ...	1·06 ...	Putrid in 2 days, goes quite black
Cinder filtrate...	·14 ...	·43 ...	Somewhat putrescent, but much better in appearance and smell than tank effluent

The Noton Shelf Filter.—This filter, which is the invention of Mr. Noton, consists of a framework supporting four lattice-work shelves, on which the filtering material is laid. The tank effluent flows over the top shelf, percolates through the filtering medium, and drips on to the next shelf, and so on to the bottom of the filter. There is 1ft. interspace between the bottom of one shelf and the surface of the filtering medium on the next. The bottoms of the shelves are constructed of laths set edgewise, with ½in. interspaces. On these the filtering medium is laid, consisting of a layer 1ft. deep of blue furnace cinders, broken down to pieces about 1½in. by ¾in. The clear area of each shelf is 6ft. by 4ft. The filter passes 5000 gallons in 24 hours, including periods of rest.

Samples were taken at the top and bottom of the Noton Shelf Filter. The analytical figures were as follows :—

	Grains per gallon.			
	Oxygen absorption, 4 hours.	Free and saline ammonia.	Albuminoid ammonia.	Chlorine.
Top of filter	·80	1·00	·16	4·3
Bottom of filter ...	·64	·98	·15	4·4

Incubator Test.—Three Minutes' Oxygen Absorption.

	Grains per gallon. Before incubator.	After incubator.	Putrescibility.
Top of filter ...	·30 ...	1·02 ...	Putrid in 2 days
Bottom of filter	·20 ...	·85 ...	do.

The above results appear to show that but little purification is effected by this filter.

Cascade Experiment.—Samples were also taken from the top and bottom of a set of wooden steps down which the effluent fell in a cascade. The analytical figures were as follows :—

	Grains per gallon.			
	Oxygen absorption, 4 hours.	Free and saline ammonia.	Albuminoid ammonia.	Chlorine.
Top of fall	·84	1·00	·16	4·4
Bottom of fall	·80	1·05	·16	4·3

Incubator Tests.—Three Minutes' Oxygen Absorption.

	Grains per gallon. Before incubator.	After incubator.	Putrescibility.
Top of fall ...	·32 ...	1·12 ...	Putrid in 2 days
Bottom of fall ...	·26 ...	1·00 ...	do.

From these results it will be seen that practically no effect is produced by aëration due to the cascade.

Nitrification.—Both the tank effluent and the cinder filtrate were tested for nitrites and nitrates practically without result. The tank effluent contained only ·013 nitrogen as nitrates, and the cinder filter ·016. No nitrites were found. Although the cinder filter effects considerable improvement in the effluent, yet the result, so far as it is reasonable to judge from an isolated sample, does not appear to be entirely satisfactory.

Supplementary samples from the Oldham Sewage Works.—Since the above report was written, a second visit was paid by the Chemist to the Oldham Sewage Works on the afternoon of February 11th. A second set of samples was obtained, and the analytical report on them is as follows :—

Description of sample.—The raw sewage sample was a mixture of samples taken at 4 a.m., 9 a.m., and 5 p.m. on February 11th. It contained a con-

siderable amount of fibrous suspended matter, which readily settled, leaving a fairly clear liquid, which was apparently diluted to some extent by the rain which had fallen during the earlier part of the day. The tank effluent sampled at 5 p.m. contained rather an excessive amount of brown suspended matter, probably owing to the increased speed of flow through the tanks, owing to rain. It was neutral to litmus. The cinder filtrate, sampled about 5.10 p.m., showed a slight white opalescence, as on the occasion of the Committee's visit. It was neutral to litmus.

	Analytical numbers (in grains per gallon.			
	Oxygen absorbed, 4 hours.	Free and saline ammonia.	Albuminoid ammonia.	Chlorine.
Raw sewage (shaken)	3·00	·70	·55	3·6
Raw sewage (settled)	·66	·70	·13	—
Tank effluent	1·82	1·15	·18	4·6
Cinder filtrate	·22	·55	·055	4·4

Incubator Tests.—Three Minutes' Oxygen.

	Absorption before incubator.	After incubator.	Putrescibility.
Raw sewage (settled) ...	·36	·28	Smells badly in 2 days
Tank effluent	·74	1·16	Black and putrescible in 2 days
Cinder filtrate	·16	·05	Remains sweet

Nitrification.—Nitrites were found to be present in the cinder filtrate, but not in the tank effluent. The total nitrogen as nitrites and nitrates was found to be as follows :—Tank effluent, ·04 ; cinder filtrate, ·25. The numbers show that under favourable circumstances some nitrification takes place. The chlorine numbers above given show that the tank effluent and cinder filtrate are fairly comparable. From the two sets of samples now examined it may, therefore, be concluded that the Oldham cinder filters give, on the whole, satisfactory results. Under occasional circumstances, as in the case with the filter at Davyhulme, a sample may be taken which is not absolutely non-putrefactive, but the amount of putrefactive change on incubation, even in such a case, is only small. The analyses of samples from other works described in this report show that nitrates are produced in greatest quantity by filtration when the sewage is largely of a domestic character. Oldham appears to be an exception to this rule ; the filters, however, have not been a very long time in use.

Chemical report. — The sewage here is much more of a domestic character than that of Manchester ; the precipitants are the same as used in Manchester, but the quantity is smaller, approximating to that in use at Barking. There is a distinctive feature in their mode of adding the lime, which there is no doubt gives greater efficiency for the quantity used over the method adopted in Manchester, and in fact at most other sewage works. The bulk of lime-water used is so great, being one-twentieth of the total sewage, that its adoption at our works would be somewhat difficult. The proportion of organic purification effected in the tanks is considerable, but the tank effluent is still decidedly putrescent. The filtration of this effluent through the cinder filters, however, practically removes this defect, and the resulting filtrate is on the whole satisfactory. We were informed that the effluent only remained one hour in these filters. In our opinion slower filtration and longer contact with the bacterial contents of the filters might be advisable.

Report as to cost and general working of filters.—One of the precipitating tanks at this place has been filled to a depth of 4ft. with clinkers and ashes as an experiment. The result was so satisfactory that the Town Council resolved on treating the whole of their effluent by biological filters, and three acres are now nearly complete. The most accurate details of cost were given, and the Mayor and the Engineer stated that it amounted to £700 per acre. This is for filters excavated to a depth of 3ft., and filled with clinkers to a depth of 28in., the sides being protected with 3in. deal plankings ; they are constructed on a natural retentive clay bottom, puddled where necessary. These appear to be the least costly filters we have seen. It is stated that these filters if charged more frequently are capable of passing over a million gallons per acre during the 24 hours.

(*To be continued.*)

Institute of Sanitary Engineers

INCORPORATED

OFFICIAL TRANSACTIONS.

THE following members have recently been elected :—

Fellows.—Chas. Abburrow, Johannesburg ; S. J. Adams, Southend-on-Sea ; J. R. Brooks, Wimbledon ; Marshall Hainsworth, Teddington ; Harold Harlock, Southend-on-Sea ; E. J. Jones, Cardiff ; J. C. Leed, Cambridge ; Hugh McLean, Nottingham ; J. N. Matthews, Doncaster ; A. Morris, St. Boswells, N.B. ; F. S. Rayner, Newhaven ; J. F. Stow, Bridlington ; W. T. Unwin, March.

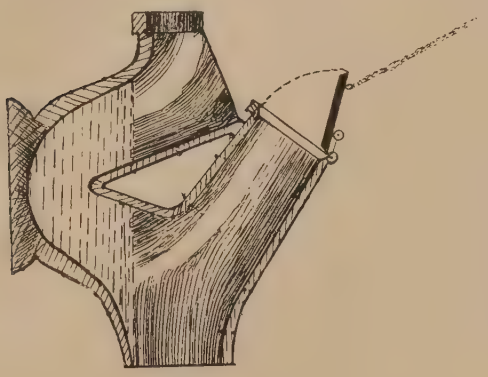
Associates.—J. H. Bridge, West Bromwich ; C. E. Butcher, London ; W. H. Chown, Lympstone, Devon ; J. S. Coverley, Penmaenmawr ; J. Davies, Carmarthen ; C. E. Getting, Sydney, N.S.W. ; H. L. Jacques, Manchester ; H. G. Mankin, London ; W. J. Mansfield, Nottingham ; W. E. Markham, London ; W. R. Nicoll, Perth ; Geo. Nuttall, Haslingden ; E. Streather, Deptford ; Wilmer Sturch, London ; J. T. Webb, Sutton ; E. Wade Wilton, Batley, Yorks.

Any of our readers desiring information concerning the Institute should communicate with the Secretary, 63, Chancery-lane, W.C.

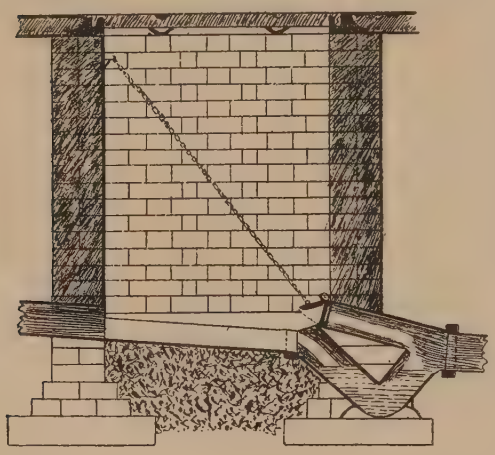
NOTICE.—The Annual Subscription to this Journal has been raised to 12s. 6d. to all NEW Subscribers. NO ADVANCE will be made to our friends whose names were entered on our Subscription list prior to March 31st, so long as they continue to subscribe.

A NEW PATENT INTERCEPTING TRAP.

We have much pleasure in introducing to the notice of our readers a new patent intercepting trap, the invention of Mr. Arthur A. Grist, Sanitary Inspector for the Board of Works for the district of St. Saviour's. The invention consists of a device by



means of which the stopper of the sweeping arm of intercepting drain traps is hinged, which not only prevents its being blown out and blocking the drain, but should it become choked from any other cause, and the inspection chamber and drains fill with sewage, it can be readily opened by means of the chain attached to it, the end of which is fixed to the



brickwork of chamber near the surface, and the sewage let off through the sweeping arm, or if the drain is choked beyond the trap, the rods can be inserted and the stoppage cleared, thus saving the very objectionable method of baling out the sewage before the stopper of the intercepter now generally in use can be taken out. This should commend itself not only on account of its great simplicity and utility, but also because it can be attached to existing traps by cementing a short length or collar with fitted hinged stopper into the sweeping arm of almost every description of intercepter at a very small outlay. It will, without doubt, be largely recommended and adopted, not only by Sanitary Authorities and Inspectors, but by sanitary engineers and the trade generally, as soon as it is placed upon the market, as it supplies a long-felt want in this direction.

THE LOCAL GOVERNMENT BOARD AND THE EXETER SEWAGE SCHEME.

THE SYSTEM SANCTIONED.

The Local Government Board have, we understand, decided to give their approval to the scheme submitted to the Exeter City Council by Mr. Cameron, the city surveyor, for disposing of the sewage of the city, and will authorise the raising of the loan required for this purpose, the amount being estimated at about £40,000. Under Mr. Cameron's scheme the whole of the sewage of the city will be carried by four intercepting sewers to the Council's property at Belle Isle and Eveleighs, where it will pass into septic tanks and become the subject of bacterial treatment. The effluent will be disposed of by filtration over land at Duck's Marsh.

Experiments have been carried on by the City Surveyor for just two years. An inquiry into the system was held a short time since by Inspectors from the Local Government Board, and it was attended by representatives of Sanitary Authorities in all parts of the kingdom. The evidence was very complete, and seemed to leave no room for doubt as to the efficacy of the system suggested by Mr. Cameron. The Local Government Board have followed up the public inquiry by careful examination on their own account, and by acquiring further information on various points as they, on consideration, presented themselves to their minds.

The Board have directed their inquiries with the view of determining two questions. In the first place, they desired to ascertain whether the final effluent obtained by the septic process was uniformly of such a character as to permit of its discharge into the river without further treatment on land. If not, was the process a sufficient preliminary to the treatment of the sewage on land, and was the land possessed by the Council suitable in quality and quantity?

We understand that the Local Government Board have come to the conclusion that if the septic process be adopted, a further treatment of the sewage on land would still be required previous to the effluent being discharged into the river. The Board are not, however, unwilling to accept, by way of experiment, the adoption of the process recommended by the City Surveyor as a method of treatment preliminary to further treatment on land. The Local Government Board will approve of the scheme on the distinct understanding that the City Council, in adopting this system as an experimental substitute for the ordinary process of chemical precipitation, will accept the entire responsibility for the experiment and will give an undertaking that, in the event of the process failing to give satisfactory results when applied to the sewage of the entire city, they will adopt in its place some process of treating the sewage with chemicals combined with artificial filtration. The Board mention, in this connection, that they understand that the tanks

can readily be made available for use as part of such a system.

With regard to the quantity of land required, the Local Government Board assent to the scheme of the Council possessing themselves of land for treating the effluent equal to that which is required under schemes in which chemical precipitation and artificial filtration are adopted—that is to say, an acre for each 2000 of the population. The Council have now in their possession, attached to the site of the works, close upon this quantity. The Local Government Board point out that they have further land at Countess Weir, some portion of which land they might probably exchange for the further quantity they will require adjoining Duck's Marsh, and which land is quite suitable for the purposes of filtration.

The Local Government Board will require the Council to protect themselves from floods, and will, therefore, stipulate for flood banks at Duck's Marsh and Belle Isle. Although the construction of these flood banks was not originally contemplated by Mr. Cameron, still this work will not be of a very serious character, inasmuch as the excavations necessary for forming the tanks will provide most of the material necessary for making the flood banks, and, indeed, will save it being carried elsewhere for disposal. The Board also deem it right to stipulate that the works shall be strengthened at certain points, their evident desire being that everything possible shall be done to minimise the chances of failure from any cause whatever.

MUNICIPAL ENGINEERS AT NORWICH AND YARMOUTH.

THE Eastern Counties district meeting of the Incorporated Association of Municipal Engineers was held at Norwich on Friday last. The members were welcomed by the Mayor (Mr. C. C. Rix Spelman) and other members of the Corporation. The chair at the Engineers' meeting was occupied by Mr. J. S. Eayrs (past president). A paper, describing some of the chief features of Norwich and the municipal engineering works in progress, was read by Mr. A. E. Collins, the City Engineer. The population of the town, it appears, is 112,000, and the area of the city 7472 acres. The rateable value is £346,553, which is regarded as extremely low, having regard to the population and area, the result being that the rates in the £ were high, being over 8s. in the £. Some portions of the drainage system still in use were centuries old, and during the past few years considerable lengths of ancient sewers had been put out of use, these being built with walls and flat bottoms. In consequence of the earlier works of sewerage being constructed so as to discharge into the river, a serious nuisance was caused, which necessitated the construction of a new main intercepting sewer, and the provision of a sewage farm of 503 acres, 268 acres of which being available to receive sewage, the mode of treatment being broad irrigation, the effluent discharging into a tidal stream. Soon after the main outfall sewer was brought into use it was found that it admitted subsoil water to an extraordinary amount, necessitating great cost in pumping to the farm. As the result, it was advised that (1) the construction of a new main outfall sewer at a higher level than the old one be constructed, and that the old one be abandoned; (2) the adoption of the Shone system for raising the sewage of the low-level districts into the new main outfall sewer; (3) the re-drainage of the whole of the city on the separate system. This work has been in progress for a considerable period, and is still proceeding. The larger sewers are constructed in concrete pipes backed with cement concrete, the smaller-sized sewers being formed with stoneware pipes, jointed with the Hassell and Parker joint.

For the construction of the sewers across the river at five points, comprising nine actual pipe crossings, various methods were adopted as circumstances dictated. At Carrow Bridge, where the river is crossed by a 12in. sealed main, a 7in. low-level gravitating sewer, and a 3in. air main, advantage was taken of the old low-level branch sewer 30in. in diameter to receive the three new pipes. The old sewer was too small to admit of the jointing of pipes within it; moreover, it was neither straight, horizontally, nor vertically. At Foundry Bridge advantage was taken of the existence of the old low-level sewer crossing, which consisted of an iron pipe 6ft. internal diameter. The size available made constructional work comparatively straightforward at this point. At Fye Bridge a 24in. sealed main, inclining from north to south, and a 9in. gravitating sewage sewer from south to north, had to be constructed beneath the bridge and below the navigation depth of the river. This work had to be done without stopping the bridge for traffic or the river for navigation excepting during a limited number of hours, and was effected as follows:—Steel pipes 30ft. long (the span of the bridge being 33ft.) were obtained; at both ends of this pair of pipes wooden yoke pieces were attached in such a manner as to secure the pipes in their proper relative positions to each other; the joints between the yoke pieces and the pipes were caulked so as to be water-tight, the sides of the yokes were grooved to receive the sheeting planks of a cofferdam, and to their tops doors were hinged; such doors afterwards formed parts of the cofferdams. The pipes having been prepared in this manner, they were floated upon a pontoon beneath the bridge, and slung from the bridge by means of proper tackle above a trench which had previously been dredged to receive them. The pontoon was then floated away, and the pipes lowered on to the dredged bed. Up to this time the doors above mentioned were lying horizontally upon the pipes, this being necessitated by the limited head-room beneath the bridge. When the pipes had been lowered the doors were raised to the vertical position, the position of the pipes accurately adjusted by the aid of marks previously placed upon the doors, and the pipes covered with concrete. Cofferdams were then driven in continuation of the small portions of such dams formed by the doors and yokes. The driving of the piles had to be effected to a great extent by means of hydraulic jacks, which abutted against the underside of the bridge. Shafts were then sunk at the landward end of both abutments and headings driven beneath the abutments into the cofferdams. This work had to be carried out at such a depth as to be in parts below the points of the piles supporting the bridge abutments. A manhole was built at each end of the river length. Through these manholes the pipes are carried in special castings provided with large access doors to enable blockages to be dealt with should they occur. Blow outs and stop valves are also arranged on the up-stream

side of each of the deepest dips to enable the pipes to be to a great extent emptied without pumping. These precautions were taken with the whole of the inverted syphons excepting that from No. 5 ejector near New Mills, where the dip is comparatively slight. The difficulties arising from the attempt to carry out the separate system in this ancient and irregularly built city were found to be so great and likely to lead to such an enormous outlay that the author, soon after his appointment, advised that, except in the low-level districts drained by means of ejectors and in new buildings and new building estates, the separate system be not proceeded with for the time being, but that the then existing combined sewers be intercepted at suitable points in such a manner that sewage and storm water up to a sufficient dilution should pass into the sewerage system, and after the pre-arranged amount of dilution had been exceeded the whole flow should pass to the river, which where any of the storm overflows exist is tidal, and below the New Mills Weir, which in its turn is some distance below any waterworks intake. The Council accepted this proposition, and since that time the works have proceeded on the lines recommended. Whilst the author upholds the separate system of sewage as the best one extant, yet the complications and expense are so great in cases similar to that which he is dealing with in Norwich, that he feels he is perfectly justified in the departure from it he has made.

For the drainage of the districts lying below the levels commanded by the new main outfall sewer six ejector stations have been constructed, each containing a pair of Shone's ejectors, manufactured by Messrs. Hughes and Lancaster. The pair of ejectors at station No. 5, near the New Mills, are the largest yet constructed, and are notable as having double inlet and outlet pipes and valves to facilitate filling and discharging. This pair of ejectors have lifted 1000 gallons per minute against a head of 14ft. 8in. through an 8in. rising main, 375 yards long, discharging into the main outfall sewer in St. Benedict's-street. The whole of the ejector stations are for the greater part of their depths below the line of saturation. Large volumes of water had to be dealt with in sinking them; in two cases pumping was of no avail, and air pressure had to be used during the excavations. Air under a nominal pressure of 15 lb. to the inch is distributed to the six ejector stations from the power station at New Mills, through 2⅞ miles of cast iron pipes, having a maximum diameter of 9in. and a minimum of 3in. As the pipes were laid, and again after completion, they were tested with air pressure at 40 lb. to the inch, and were not accepted unless the losses from all causes amounted to less than 5 per cent. of the absolute initial test pressure in one hour.

Mr. Collins then went on with considerable detail to describe the air-compressing machinery. The method adopted for raising the refuse is special, and was due to the fact that sufficient space was not available for the construction of an inclined road to the top of furnace setting, which is higher than usual above ground level because of the liability of the site to floods and the desire to keep the flues, &c., dry. The method in question is as follows:—A sunk rail pit has been constructed in such a manner as to enable the house scavenging vans to tip their contents into trucks running on rails in the rail pit. The trucks are each of equal capacity to that of a van. When refuse is required for the furnaces an overhead rope-driven traveller, which commands the rail pit and the furnace top, raises the body only of a truck, travels with it to the charging hole of a furnace, where the truck bottom is opened and the refuse is deposited; the empty truck is then returned by the traveller to its wheels. A sufficient length of rails has been provided to accommodate twelve trucks, and storage for additional truck bodies is being provided at the level of the furnace top. The six trucks included in the experimental delivery do not give quite satisfactory results, as in consequence of the local practice of collecting every class of refuse, a large amount of fibrous material such as straw, &c., has to be dealt with which does not fall through the openings in the truck bottoms freely. It is intended to adopt a different arrangement for the remainder of the trucks and to alter the six experimental ones. The new trucks will be provided with trunnions to enable them to be tipped, and thus emptied. The flow of the river Wensum, which has an average fall of 6ft. 6in. at New Mills, offers an alternative to the steam plant for actuating the air compressors. The old-fashioned small sluices which formerly existed at New Mills caused river floods to be greater than they should have been, due to a great extent to the tendency they had to become blocked with *débris* brought down by the river. In constructing the new works, advantage has been taken of the late Mr. Stoney's invention, and a sluice on his principle, 14ft. 3in. wide by 8ft. deep, has been provided. This sluice was supplied by Messrs. Ransome and Rapier, of Ipswich. It can be raised or lowered with the full head of water against it by one man. Mr. Collins concluded his interesting paper with a description of the Free Library and Baths.

A ROUND OF VISITS.

The rest of the afternoon was spent in a round of visits of inspection. A time table had been drawn up by Mr. Collins with such good effect that the visitors, who were conveyed rapidly from point to point in pair-horsed wagonettes, were able to see not only the principal engineering features of the city, but two or three places of general interest. They first rode down to St. Andrew's Hall in order to see how the pneumatic painting machine does its work. The lightning painter, one of Messrs. Wallwork and Well's patent, is so new an invention that though Norwich is not exactly the first of the provincial towns in which it has been employed, most of the visitors had to confess that they had had no previous experience of it. Undoubtedly it represents an enormous advance upon the old system of painting by brush, and particularly so in cases where there are large wall spaces to be covered.

Some twenty minutes having been occupied in seeing how the machine adapted itself to stencilling and other tests demanded of it, the party proceeded to the New Mills air-compressing station. Here machinery has been erected for lifting the sewage to higher levels, in accordance with the principles of the Shone system, the power being transmitted through cast iron air mains to the various ejector stations in the streets.

After luncheon a visit was paid to Carrow Works, which came not strictly within the sphere of muni-

cipal engineering. But at Carrow there is so much of mechanical interest to be seen that Mr. Collins, knowing that his party could not go away without visiting the adjacent pumping station, undoubtedly did well to procure admission to a few of the departments. The party next inspected the Trowse Drain Outfall Sewerage Station, where by means of extremely powerful machinery the sewage is pumped up to the sewage farm. From thence they drove to the Castle Museum, where Mr. Collins conducted the party to the battlements and showed them the principal objects in the panorama lying around about.

In the evening the members of the Association dined together at the Maid's Head Hotel. Mr. Eayrs again presided, and there were about sixty-five members present.

NATIONAL HEALTH SOCIETY.

HER Royal Highness Princess Christian, attended by Colonel Martin and Miss Emily Loch, on Saturday presented the diplomas, medals, and certificates gained by the successful candidates at the various classes and examinations held during the past year by the National Health Society. The ceremony took place at Grosvenor House, by permission of the Duke of Westminster, who, as president of the Society, occupied the chair. There was a large attendance of ladies and gentlemen.

The DUKE OF WESTMINSTER, in opening the proceedings, said that he had been twenty-one years president of the Society, and nothing could be more satisfactory than the extraordinary and increasing success which had attended its operations. The number of certificates to be presented was less this year than last, but this was only because of the large growth of the work in the country districts. Examinations were now held at centres so far removed from town that it was not possible for the successful candidates to be present. Lectures and examinations were now, in fact, held all over Great Britain and Ireland. The Society now examined classes and granted certificates to the quarter-masters of the regiments stationed at Aldershot, the Duke of Connaught having ordered that they should have instruction in hygiene and sanitation. This knowledge would be of the greatest possible value to them in their Army work. The Society had to deplore the loss of Mr. Ernest Hart, the chairman of the Committee, who had done excellent work for many years. His place had been worthily filled by the Rev. C. J. Ridgeway.

Princess Christian then presented the awards, and this was followed by an address by Sir A. ARNOLD, who, referring to the death of Sir Robert Rawlinson, said that event could not fail to raise thoughts of the great improvement in our national health which had taken place during the last half-century. The humblest dwelling in Whitechapel was to-day in a better sanitary condition than were then the residences of the most distinguished and august people in the land. That being so, to what might we not look forward in the future? There could, however, be no satisfactory reform without instruction, which the Society gave, and therefore its work deserved the heartiest support at the hands of all classes of her Majesty's subjects.

The Rev. C. J. RIDGEWAY moved a vote of thanks to her Royal Highness, and

Sir J. CRICHTON-BROWNE, in seconding, mentioned that during her Majesty's reign the deaths from tubercular diseases had decreased two-thirds. This exactly corresponded with the advance in sanitary science.

The resolution having been carried amid loud cheers, Princess Christian bowed her acknowledgments, and the proceedings were closed with a vote of thanks to the Duke and Duchess of Westminster.

CONSUMPTION: SUGGESTION TO SANITARY AUTHORITIES.

AS a means of spreading information upon this important subject, Sanitary Authorities could undoubtedly accomplish much towards the prevention of consumption by issuing a circular like the following :—

THE PREVENTION OF CONSUMPTION.

Instructions to Consumptives and their Friends.—Consumption is a dangerous communicable disease. One consumptive may spread the disease to very many healthy persons. The chief danger exists in the expectoration of the consumptive person, and if this expectoration is carefully destroyed before it is dried, little danger need be feared.

Consumptives should be instructed not to spit upon sidewalks, the floors of rooms, public halls, street and railway carriages, and other vehicles, or anywhere that the sputum may become dry, for in the dried state the wind, trailing skirts, the act of sweeping, &c., diffuse the germs, so that they may be readily inhaled and swallowed ; nor should they spit where fowls or dairy cows may take in the sputum, or the dust of it with their food. They should spit into pieces of cloth, or receptacles made for the purpose, containing a saturated solution of carbolic acid (one part of carbolic acid crystals to about fifteen parts of water). Such pieces of cloth should be destroyed by fire, before the sputa become dry, and other receptacles should be cleansed with scalding water, their contents having been destroyed or otherwise carefully disposed of. Handkerchiefs which may have been used from necessity should be boiled half an hour before washing.

A healthy person should not sleep in a room with a consumptive.

Remember that sputa must never be allowed to become dry.

A circular on the "Restriction and Prevention of Consumption" will be forwarded to any person upon application.

HAMPTON.—The County Analyst for Surrey has made an examination of two samples, taken from the sewers at the manhole in Lower Teddington-road. He reports that one sample had a very "tarry" smell, and light oil floated on the surface. This pointed to the presence of mineral matter far higher than in ordinary sewage. The inference drawn from this report is, that the gasworks of the neighbourhood are discharging refuse into the drains. A notice is to be served on the gas company to discontinue the practice.

Annotations from Annual Reports.

Scarlet Fever and Dairy Supplies.—The following extract from the report of the Medical Officer of Health for the Borough of Halifax affords a striking instance of how disease may be spread through negligence on the part of those responsible for milk supplies:—"On Saturday, the 19th June, eight cases of scarlet fever were notified to the Health Department, and five more on the following Monday, the 21st. As this was an unusual number for us to receive in two days, especially from one district, viz., Saville Park, Inspector Archbell received instructions on the Monday morning to visit the address of every notified case, and ascertain the milk supply in each case. In less than two hours we had the information that every one of the reported cases received milk from one or the other of two purveyors, Mr. Valentine and Mr. Fell, the latter being only a dealer, living in the immediate neighbourhood. The Inspector called upon him first and satisfied himself that there was no cause of suspicion in Mr. Fell's house. Inquiring of Mr. Fell as to his milk supply, the Inspector was informed that he received about five gallons a day from a Mr. Valentine, a farmer, living about a mile on the west side of the town, and a larger quantity also from a farmer in Warley. The Inspector then visited the latter place, and could find no trace of scarlet fever there. He then went to the farm of Mr. Valentine, and found evidence of scarlet fever in several members of the family, who had been or were ill, without any medical attendant. All this was reported to me at noon of the same day, and, accompanied by the Chief Inspector, I went at once to the farm and found a boy, aged thirteen, fresh in the fever, had a good rash out and sore throat, &c., and going freely about the premises, in and amongst the cows. Mr. Valentine himself was in bed with a sore throat, and Mrs. Valentine showed some signs of desquamation, although she stoutly denied having been ill. Besides the above there was an elder son aged nineteen, who took the milk to the town, and a farmer's man, who did the milking and other work on the farm; the latter had not complained of anything, but the elder son had had a very sore throat, and still kept to his work. Here, of course, was the source of all the mischief."

Law Cases.

THE POLLUTION OF RIVERS.

THE case of West Riding of Yorkshire Rivers Board *v.* Goldthorpe and Another was heard last week in the High Court (Queen's Bench Division), before Mr. Justice Day and Mr. Justice Lawrance, under a special Act of Parliament (the West Riding, Yorkshire, Rivers Act, 57 and 58 Vict., cap. 166) by way of appeal from the Quarter Sessions of the West Riding of Yorkshire at Leeds. The case had been argued before another Divisional Court last sittings, but that Court had been of opinion that the facts should be considered as well as the law, and eft the matter open.

Mr. Tindal Atkinson, Q.C., Mr. Longstaffe, and Mr. Roskill had appeared for the appellants: Mr. Cripps, Q.C., Mr. T. R. D. Wright, and Mr. T. Ellison for the respondents.

The appellants were the River Board; the respondents were corn mill owners on the river Don. The question was whether the respondents had committed an offence under Sec. 5 of the Act, which prohibited the deposit of mud, sludge, or solid matter in a river. The process of the respondents was to collect in the mill dam the water that worked the mill, by reason of which a deposit was created. Periodically this deposit was shovelled out into the stream and allowed to be washed down. Evidence was given that as much as 300 tons in one day was thus sent down, and a sample of dark-coloured water was put in evidence. There is a proviso in the Act that no person should be deemed to have committed an offence for putting or permitting to be carried into any such river any sand, gravel, or natural deposit which should have flown in or been deposited by the current of any such river or stream, provided that the sand, gravel, or other natural deposit so put back or carried as aforesaid did not interfere with the due flow of or pollute the water of such river. The justices and the Quarter Sessions had refused to convict on proceedings taken under the Act.

The Court dismissed the appeal.

Mr. JUSTICE DAY said he concurred with the decision of the Petty Sessions and the Quarter Sessions, which was a Court very largely attended by justices who knew the locality and the river in question. The proceedings were taken under an Act entitled "An Act to make more effectual provision for preventing the pollution of the rivers of the West Riding of Yorkshire and their tributaries." He had a bias in favour of such an Act, for the pollution of rivers in the teeming populations of the day was deserving of condign punishment. But this was not a case for a prosecution. The respondents were people who kept a flour mill—one of the most ancient industries in the country. This was a rural flour mill, the first mill on the Don. There were many others lower down on the same river, and there were also manufactures below in towns. Grinding corn was not a pollution of either air or water. In a certain sense, however, the respondents had caused an influx of solid matter into the river. His Lordship read the preamble referring to the "polluted and filthy condition" of the rivers and Sec. 5 of the Act. Commenting on the latter, he said that general words must be treated as associated with the other special words of the section. A rural mill for grinding corn was not the same class of thing as the manufactures or other matters mentioned in the Section. The Act was meant to prohibit the putting into the river the dirt, &c., that came from manufactures such as one met with in towns. He did not see that in this case anything more was put into the river than the river itself brought down, which was an exception within the Act under Sec. 6 (3). In his opinion, Sec. 5 did not apply to "the cleaning out" a natural deposit of a mill dam. That was a natural deposit ordinarily associated with a mill pond when the water was torpid for a certain time. This was not an offence under Sec. 5, and, if it were, it would come within the exception.

Mr. JUSTICE LAWRANCE concurred. The main object of the Act was to prevent the pollution of

rivers. There must be either pollution or interference with the clear flow of the stream. There was no evidence of pollution in the proper sense of the word in this case. What was done was that the mud was periodically stirred up and sent down the stream. It was mud that was naturally found in the river. The magistrates below were quite right.

General News.

CHATHAM.—It is stated that measles has broken out in this town, and that the Medical Officer has ordered the closing of all schools.

BIRMINGHAM.—It is announced that Messrs. Morrison and Mason, of Glasgow, have secured the contract for the water supply extension for Birmingham. The contract price is half a million sterling.

SOUTHWARK.—Another open space has been secured in this populous district. The Vestry and the London County Council have purchased a plot of ground from Lord Llangattock, the contribution of the former amounting to £3400.

LONDON.—A letter has been received by the Vestry of St. Luke's from the Burgomaster, stating that the City of Cologne had resolved to get rid of its refuse by burning. A deputation was about to travel to England in order to inspect the arrangements made by the various towns in which destructors were employed, and asking permission to inspect the destructor of the parish.

SEVENOAKS. — The Medical Officer of Health has made an analysis of the water supply for the Urban District Council. From his chemical examination in May he found the sample to be an excellent water for drinking and domestic purposes, whilst from bacteriological examination, in which Dr. Tew made a special search for the typhoid and coli bacilli, the result was entirely negative—from a bacteriological point of view the water was pure and uncontaminated.

HAMPTON COURT.—Another interesting discovery has been made in the course of the excavations for the effluent pipe of the new Thames Valley drainage, along the towing path of the Palace Gardens at Hampton Court. Last Friday, between the railings of the private gardens opposite the end of Queen Mary's Bower, the foundation of the old water gate, or "water gallery," built by Henry VIII., was cut through. The walls or piers were found to be of immense thickness, not less than 25ft. wide, and constructed of the hardest chalk faced with stone. It is said that the opening through which the State barges once passed is clearly discernible.

CAMBORNE.—The official report of Dr. R. Bruce Low, one of the Medical Inspectors of the Local Government Board, on the outbreak of typhoid fever in the urban district of Camborne, and in portions of the adjoining rural districts of Redruth and Helston, has just been sent to the members of the Councils affected. The outbreak occurred during December and January last, and was reported to the Local Government Board on December 15th by Dr. Telfer Thomas, Medical Officer of Camborne, and subsequently by Dr. A. E. Permewan, of Redruth, and Dr. N. H. Haswell, of Helston. The report concludes:—"The sanitary condition of Camborne and Illogan, as well as of parts of Crowan, is far from being satisfactory." The appendices include the recommendations of Dr. Reece in 1894, which are referred to in the report. Those deal with the water supply, isolation provision, excrement and refuse disposal, insanitary dwellings, and the provision of houses for the working classes, and overcrowding of persons in houses.

ABERDEEN.—Three new wings are to be added to the City Hospital, according to designs by Mr. John Rust, city architect, at a cost of £4650.

ROTHERHITHE.—At its last meeting the Vestry accepted the tender of Messrs. Henry Knight and Son, of Tottenham, for the erection of dust destructor buildings, at a cost of £3933 10s. 6d.

KNARESBOROUGH.—The Urban District Council has appointed a deputation to meet the Harrogate Corporation and the Knaresborough Rural District Council with respect to the provision of an isolation hospital for the district.

LEAMINGTON.—The Local Government Board has intimated its intention of sending an Inspector to inquire into the proposal of the Corporation to borrow £5500 for works of water supply, and £5010 for purposes of public walks and pleasure grounds.

CARNARVON.—At a recent meeting of the Town Council a long discussion took place touching a recommendation by the Sanitary Committee that a new reservoir be erected at Ysbytty, and that a new 8in. main be laid from there to the town at an estimated expenditure of £3309. The Committee's reccommendation was eventually adopted.

DOUGLAS (ISLE OF MAN).—The Corporation has decided to increase its water supply by the construction of a reservoir at West Baldwin capable of containing 300 million gallons. This will place Douglas in a magnificent position and provide for the requirements of the borough for the next generation. The holding capacity will be six times that of the Clypse reservoir. It will take five years to complete the new scheme, which will place Douglas with regard to its water supply in as good a position as any borough of the same size in the United Kingdom.

LAMBETH.—Dr. Priestley reports a death-rate of 14·6 per 1000 for the four weeks ending May 21st. Considering the immense area of the district, this compares very favourably with that of the metropolitan area, which was 16·4 per 1000. At the last meeting of the Vestry the Surveyor, Mr. James P. Norrington, tendered his resignation. He gave as his reason that it was impossible to carry out his duties efficiently with "the present insufficient staff." We think there must be good ground for this complaint, for Lambeth is notoriously in arrears with its work; and this state of affairs will continue, unless the Vestry obtain the help of contractors to make up some of the roads—work which in some cases has been paid for by the owners months ago.

BARMOUTH.—On Saturday Barmouth new waterworks were formally opened by Mr. T. W. Russell, M.P., Parliamentary Secretary to the Local Government Board. These works are situated amongst the Merionethshire mountains, and the reservoir contains a storage of 100 million gallons, of which 52 million gallons are for the supply of Barmouth, and will supply a population of 20,000 for 104 days. The works cost nearly £30,000. At a banquet held in the afternoon Mr. T W. Russell, in reply to the toast of "The Local Governing Bodies of the United Kingdom," spoke of the enormous and increasing work of the Local Government Board, and said that since its establishment it had sanctioned the spending upon sanitary work of £162,760,000. Whereas before the establishment of the Central Authority the expenditure upon sanitary work in the kingdom during ten years was only £2,956,000, the sum spent during the last ten years was £46,000,000. With due deference to those in favour of decentralisation, he contended that there was no tribunal in the United Kingdom where more fair play was shown than in Committees of the House of Commons and the House of Lords. He was in favour of the principle of local tribunals to deal with local affairs, but the difficulty was to find the best plan for devolution, and he did not look forward to a speedy settlement of that problem.

LONDON.—At the meetings of several of the Vestries last week it was reported that their horses had taken prizes at the great Cart Horse Parade at Regent's Park on Whit Monday.

BRADFORD-ON-AVON.—New baths have been erected at Bradford-on-Avon, as a memorial of the Queen's Diamond Jubilee. The cost of the baths is about £1400, and the style of the buildings is Gothic, Mr. S. Howard, Town Surveyor, being the architect.

WEST HARTLEPOOL.—Although the rate of mortality in West Hartlepool just now is down to 9·23 per 1000, the satisfaction to be derived from this apparently healthy condition of the borough is, Dr. Gourley reports, marred by the alarming mortality from pulmonary phthisis. It appears that during the period—one month—covered by Dr. Gourley's report, 25 per cent. of the deaths arose from phthisis. The Medical Officer regards this as a very serious matter, especially when it is remembered that more precautions are taken for the prevention of tubercular diseases in West Hartlepool than in most other towns. The doctor exonerates the meat and the milk, and concludes that the infection is inhaled with the air we breathe.

NEWINGTON.—This parish claims to be the pioneer in the matter of refuse disposal. Many years have elapsed since its first depôts were opened, and now further extensions are contemplated. A report from the Roads and Depôt Committee recommends the obtaining a loan of £5000 from the London County Council for the extension of the high-level dust sidings at Walworth, the construction of coal bunkers at the baths establishment, and the erection of three flats for the accommodation of Vestry employés. The sidings were originally designed to receive twenty-nine trucks, and were provided when the refuse of the parish was under 30,000 tons per annum. The great developments of recent years, together with the more rapid collection of street refuse, had more than doubled this quantity, hence the enlargement. It is stated by the chairman of the Committee that Newington removes its dust at a cost of 1s. per ton less than many other large parishes. One item in the above report is open to criticism. To spend £1897 on the erection of flats to accommodate three families is rather a big order. No wonder some members are of the opinion it would be cheaper to pay the men higher wages and let them find their own houses.

LONDON (CITY).—The following interesting abstract is taken from a report just presented to the Court of Common Council:—It is stated that some years ago the Corporation, with a view of testing the asserted monopoly of the New River Company to supply water to the City at prices reckoned on the rateable value of the premises without consideration as to the amount consumed, sank an artesian well in Stoney-lane, Houndsditch, to supply the artisans dwellings there. The quantity of water raised daily is about 33,000 gallons, or over 10 million gallons a year. Of this quantity about 22,000 gallons a day, or seven millions a year, are used for the purposes of the dwellings, leaving an available daily surplus of 11,000 gallons. The average quantity of water used annually for street watering and washing is 41 million gallons, for which the New River Company charge 9d. per 1000 gallons. The annual cost of pumping the water now supplied to the artisans' dwellings is £180, or about 5½d. per 1000 gallons, while the cost of the well has been £5610. The original charge made by the New River Company for a constant supply to the dwellings was £84 per annum. Thus the Corporation by their experiment have not only sunk nearly £6000, but are losing £100 a year in the expense of supplying the water. There are no means, without great additional expense, of utilising the surplus daily supply for watering the streets, and the Corporation have decided not to attempt it.

STOURBRIDGE.—The Local Government Board has issued a Provisional Order to the Urban District Council, authorising it to acquire two fields on which to erect a refuse destructor for its district.

HAYDON BRIDGE.—The Hexham Rural District Council has engaged Mr. Harry W. Taylor, of Newcastle-on-Tyne, to prepare a scheme for the water supply of Haydon Bridge, Northumberland.

COLNE.—The Town Council has resolved that the seal of the Council be affixed to an agreement for the purchase of thirty acres of land for the purpose of erecting an infectious diseases hospital thereon, at a cost of £2100.

HOPE.—The Parish Council has had referred for its consideration a report which has been prepared by Messrs. Sterling and Swann, civil engineers, of Chapel-en-le-Frith, for the supply of the village of Hope with water from Crookstone.

Personal.

MR. J. F. TABB has been appointed Medical Officer for the Greenwich East district.

MR. W. J. BOWDEN has been appointed Medical Officer of the Glossop union workhouse.

MR. F. WRIGHT has been appointed Medical Officer for the Escrick out-relief union, York.

MR. JOHN STORE has resigned the position of Town Clerk for Bath, after forty years' service.

MR. A. J. SAISE has been appointed Inspector of Nuisances for the urban district of Kingswood.

MR. HENRY JOHNSON has been appointed Inspector of Nuisances for the urban district of Wimbledon.

MR. R. B. SIDEBOTTOM has been appointed Medical Officer for the Whitfield district of Glossop union.

MR. W. T. DAVIES has been appointed Medical Officer for the second and third districts of Hertford union.

DR. STAINTHORPE has been reappointed Medical Officer for the Urban District of Skelton and Brotton.

MR. S. R. CHRISTOPHERS has been appointed Assistant Medical Officer of the Mill-road Infirmary, West Derby.

MR. W. D. WIGGINS has been appointed Assistant-Medical Officer at the Greenwich union workhouse and infirmary.

MR. R. BROWN has been appointed Surveyor and Chief Sanitary Inspector for the Vestry of St. Mary, Stoke Newington.

MR. WM. JAMESON, Assoc. of the San. Inst., has been appointed Assistant Sanitary Inspector for the borough of Scarborough.

MESSRS. J. HEMINGWAY and G. W. BRABYN have been appointed Medical Officers for the South Wimbledon districts of Kingston union.

DR. J. W. HUNT has been appointed Medical Officer for No. 7 district under the Hackney Board of Guardians, at a salary of £80 per annum.

THE Local Government Board has sanctioned the re-appointment of Dr. T. B. Young as Medical Officer to the Halesowen District Council, at a salary of £80 per annum.

Sewerage Schemes.

[To Municipal Engineers and Surveyors.—The Editor will be pleased to receive items for publication relating to sewerage schemes projected or inaugurated, together with explanatory diagrams or photographs. The former should be drawn and lettered in black ink.]

The Tunstall Urban District Council has received the sanction of the Local Government Board to a loan of £22,300 for purposes of sewerage and sewage disposal.

The Wood Green Urban District Council has received a letter from the Local Government Board sanctioning the borrowing of £1549 for works of sewerage, £654 for purposes of public pleasure grounds, and £900 for Fire Brigade purposes.

At the last monthly meeting of the Lanchester Parish Council plans for the Lanchester village sewage disposal works, prepared by Mr. J. E. Parker, A.M.I.C.E., at an estimated cost of £1700, were considered, and the Council ordered the question to remain in abeyance for twelve months.

At a recent meeting of the Harrogate Town Council the Borough Surveyor (Mr. S. Stead) presented Mr. Dibdin's reports on the results of the analysis of the sewage, and submitted a sketch plan as to arrangement of bacteria beds which would be most suitable for the treatment of the sewage, and also his analyses of samples of sewage in effluent. It was resolved to adopt Mr. Dibdin's report, and that the same be printed and sent to each member of the Council.

At a recent meeting of the Leigh Council a heated discussion took place *re* the condition of the Leigh sewers, which cost £28,000 a few years ago. Several members said some of the main sewers were gradually silting up with solid mud, through the fall being scarcely perceptible. It was argued that had a deep sewer system with pumping arrangements been adopted, instead of the present nearly flat sewers, the cost would have been about £50,000 more. Further discussion was postponed until the Council's Surveyor had fully reported upon the condition of all the Leigh sewers.

The negotiations between the Derby Borough and County Authorities with a view to settling the dispute in the matter of sewage disposal, are progressing satisfactorily, and there are hopes of averting the litigation which the County Council threatened. On Wednesday evening, the 8th inst., the Town Council sat in Committee, when the Mayor, who has been interviewing Lord Waterpark (chairman of the Public Health Committee of the County Council), reported progress, and a Sub-committee was appointed with certain powers for the purpose of helping forward the final settlement.

The Castle Donington Parochial Authority met recently to receive and consider the plans of the proposed sewerage scheme for the parish. The proposed sewerage scheme, which is very extensive, has been under the consideration of the Parochial Authority now for several years, and the Committee has taken great pains in trying to get the very best scheme possible. The following resolution was passed by the Committee: "That the Parochial Authority of Castle Donington approve the sewerage and drainage plans as submitted, and recommends its approval by the Castle Donington District Council; and requests that Authority to instruct the civil engineer to draw up the necessary tracing to be submitted for the approval of the Local Government Board."

The Thames Conservators have prosecuted the Hartley Wintney District Council for alleged pollution of the rivers Hart and Whitewater, these being tributaries of the Thames. The case was dismissed, and the Conservators had to pay £3 3s. costs.

The Hambledon Rural District Council has been summoned before the magistrates by the Thames Conservancy Board for allowing the pollution of the tributaries of the Thames at Haslemere, Bramley, Wonersh, and Shalford. As steps are being taken to provide a drainage scheme, fines of £5 only were inflicted in the first three cases. At Shalford the matter has been dragging on for three years, and as there is no scheme the Council has been fined £30.

The Grange-over-Sands Urban District Council has adopted plans, and is making application to the Local Government Board for powers to borrow £10,000 to carry out certain improvements which have been under consideration for 3½ years. It is proposed that the sewage, which now drains upon the foreshore at various points, shall be collected and carried beyond the town along the railway embankment, outside which will be erected a promenade. The new sea wall will reclaim 5¾ acres of land, which will probably be used as a recreation ground.

An unopposed Bill to confirm a Provisional Order under the Land Drainage Act, 1861, relating to Hacconby Fen, Lincolnshire, recently came before the Chairman of Committees of the House of Commons. The object of the Order is to authorise a certain area in Hacconby Fen being constituted a separate drainage district, and to sanction the appointment of a Drainage Board of twelve members. A sub-section that the consent of the Black Sluice Commissioners should be obtained before the separate drainage area should be constituted was deleted, and the Bill as amended was ordered to be reported to the House.

After duly considering the report of the deputation which the Enderby Local Sanitary Authority recently sent to inspect the system of sewage disposal at Birstall (Yorkshire), the Committee has come to the unanimous opinion that a system with less elaborate machinery would, in a village like Enderby, very well answer the purpose, and consequently it was agreed to obtain all information possible respecting other systems. At a special meeting of the Local Sanitary Authority a letter was read from Mr. J. B. Everard, C.E., in which he advised that Dibdin's bacterial system of sewage disposal should be tried. After considerable discussion, it was unanimously agreed to ask Mr. Everard to submit plans and estimates of the system mentioned for the further consideration of the Committee.

A Local Government Board Inquiry has been held at Kessingland relative to the application of the Rural District Council to borrow £1200 for the purpose of sewerage and sewage disposal for the parish. Dr. Wynne informed the Inspector that the scheme related to that part of the village near the sea. The water would be pumped up and passed through bacterial tanks at a distance from dwelling-houses. It was hoped the effluent from the tanks would be such that it could be passed into the marsh dykes without being a nuisance to the inhabitants, or harmful to cattle. Mr. Filby the representative of the engineer, explained the details of the scheme, and said, in reply to a question, that it was not at present intended to deal with closets. The standard of purification would be very high. The rector objected that the upper village, whose rateable value was double that of the lower, would have to pay for the scheme and yet derive no benefit.

THE Local Government Board has sanctioned the borrowing by the Steyning District Council, on security of the rates, of £9100 for works of sewerage at Southwick, in the matter of the Southwick and Portslade drainage scheme, the loan to be repaid in a period not exceeding thirty years.

A LOCAL GOVERNMENT BOARD inquiry has been held respecting an application by the Newcastle Corporation for sanction to borrow £6500 for works of sewerage, and £833 for works of refuse disposal. The Town Clerk explained that the application for sanction to borrow £6500 was for the purpose of constructing sewers on the east and west side of the Ouseburn, near to its junction with the river, to take all the river sewage which now discharged into the open burn from several large sewers. Up to a few years ago the Ouseburn had really been an open sewer in consequence of sewage running into it, and it had become such a nuisance that it was necessary for the public health to divert the sewage from the Burn into common sewers. The £833 was for refuse disposal works at Elswick.

Lighting.

THE General Purposes Committee of the South Hornsey District Council recently reported that it had considered the question of incandescent lighting, and recommended that High-street, Stoke Newington, and Seven Sisters'-road be lighted with the holophone globe arrangement.

THE Blackheath and Greenwich District Electric Light Company has written the Lewisham District Board that it was concluding negotiations for the purchase of a site for its electric light station at Blackwall Point, which would be conveniently situated for the erection of a dust destructor, and that the company would be glad to enter into negotiations with the Board with a view to the erection of such for destroying the house and other refuse of the district. Referred to the Works Committee.

THE Board of Trade has issued copies of the new Provisional Order which it has just issued to the King's Norton Rural District Council, authorising it to supply electricity "for all public and private purposes" within the parishes of King's Norton and Northfield. The Order will come into operation as soon as it receives the confirmation of Parliament, and within two years from that time the Order requires the District Council to lay distributing mains along the principal thoroughfares.

As announced last week, the Local Government Board has issued a Provisional Order to the Corporation of Leeds to enable it to acquire the undertaking of the Yorkshire House-to-House Electricity Company, Limited. We now learn that the Order empowers the Corporation to create and issue such amount of Leeds Corporation stock "as will produce, by the interest or dividends thereon, an annuity of 5 per cent. per annum upon the sum properly expended by the company upon the undertaking, and chargeable to capital account," together with an amount equal to 5 per cent. on the capital for compulsory sale before the expiration of ten years from July 3rd, 1891. The Order further empowers the Corporation to make the stock redeemable "only by agreement between the Corporation and the holders of the stock for the time being," or if the company shall by arrangement with the Corporation agree to accept any part or the whole of the consideration in money, then the Corporation is authorised to issue "such amount of redeemable stock as shall be necessary to raise the amount of such payment in money."

IT is reported that a Provisional Order has been granted for the lighting by electricity of Penarth.

EARLSTON GAS COMPANY, after paying a dividend of 10 per cent. on last year's business, has just reduced the price of gas 10d. per 1000 cubic feet—namely, from 6s. 8d. to 5s. 10d. The North British Railway Company has refused to light the railway station with gas instead of oil on account of the expense, a numerously-signed petition to that effect having recently been presented to the company.

AT a recent meeting of the York City Council the Electric Lighting Committee reported that the Local Government Board had issued its sanction to the borrowing of £20,000 for electric lighting purposes, the money to be repaid within a period not exceeding twenty-five years from the date of borrowing. Professor Kennedy reported that Messrs. Crompton and Co. now found they could not recommend the lowest priced engines accepted by the Corporation. The Committee therefore had decided to instruct Messrs. Crompton to obtain the better-class engines mentioned in the tender, and the cost of the plant would therefore be increased from £8176 to £8654. The report was adopted.

A MEETING of Perth Gas Commission was held recently, to consider the estimates of the revenue and expenditure for the year, from 30th April last to 30th April, 1899. The total expenditure is estimated at £23,770 0s. 8d. In connection with the new gasworks a sum of £30,000 is proposed to be borrowed at 3 per cent., adding to the interest account the sum of £900. This latter is, of course, the principal feature of the estimates this year. To meet the estimated expenditure, including the interest for the new loan of £30,000, it is not proposed to make any increase in the gas rate. After consideration the estimates were adopted, and it was agreed, as stated, that the rate be the same as last year—3s. 2d. per 1000 cubic feet.

THE Board of Trade has just issued two new Provisional Orders, dealing with the electric lighting of the Holborn and St. Giles districts. By the first of these Orders the County of London and Brush Provincial Electric Lighting Company, Limited, are allotted an area, comprising so much of the district of the Holborn District Board of Works as lies west of the Gray's Inn-road and north of High Holborn, including Gray's Inn and Furnival's Inn, and so much of the district of the St. Giles District Board of Works as lies north of High Holborn and New Oxford-street. By the second of these Orders the Charing Cross and Strand Electricity Supply Corporation, Limited, are empowered to supply an area comprising the districts of the Holborn and St. Giles Boards of Works south of the area granted under the first Order, including Lincoln's Inn and Staple Inn.

TO OUR READERS.

The Editor solicits the co-operation of readers in making THE SANITARY RECORD *more attractive by means of pen-and-ink sketches, photographs, and diagrams. There are many phases of sanitary work which lend themselves admirably to illustration. By this means not only individual articles, but the journal as a whole will be brightened.*

Notes and Queries.

[Subscribers have the privilege of obtaining advice in this column on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed to THE EDITOR, "Notes and Queries," THE SANITARY RECORD, 5, Fetter-lane, London, E.C.

NOTE.—If an answer be required immediately, a stamped addressed envelope must be enclosed, when we will endeavour to furnish a copy of the answer by post, as owing to the large number of queries received we cannot guarantee the insertion of a reply in the succeeding issue.

1118.—HIGHWAY: ENCROACHMENT ON: PROCEEDINGS.—"J. G." writes: "In the parish of A, in a rural district, several encroachments have been made on the highway by owners of property. Will you please advise whether the Parish Council can take proceedings under the Highway Acts?"

Answer.—No. The Parish Council have no powers to take proceedings under the Highway Acts. It is the duty of the Rural District Council to do so. The Parish Council may call upon the Rural District Council to take the necessary steps, and if they refuse to do so, Sec. 26 of the Local Government Act, 1894, enables the Parish Council to make complaint to the County Council, but the Parish Council are not enabled to institute legal proceedings to have the encroachment removed.

1119.—STONEWARE AND EARTHENWARE PIPES FOR DRAINS: DISTINGUISHING CHARACTERISTICS.—"J. E. L." writes:—"Will you kindly tell me the difference between a glazed stoneware pipe and an ordinary salt-glazed pipe, as I have never seen the difference stated? There are several manufacturers of drain pipes around here, but all the pipes they make are from fireclay. As this question was asked me at one examination, I shall be very pleased if you will answer it for me."

Answer.—Stoneware pipes are manufactured from clays obtained from Dorsetshire, which are more impermeable, tenacious, and stronger than fireclay or earthenware pipes. Numerous manufacturers throughout the country now claim that they are enabled to make stoneware pipes, and an analysis shows in many cases that the claims of these manufacturers are justified. Hence many firms now make and advertise both classes of pipes, *i.e.*, stoneware and earthenware. Stoneware pipes are, however, more costly than earthenware, but, being more tenacious, are made with a thinner crust than earthenware pipes. Fireclay or earthenware pipes, which are frequently advertised as salt-glazed pipes, are made from the fireclay beds of the coal measures. They vary considerably in their tenacity, porosity, and ductility, and many firms' earthenware pipes we have tested are not sufficiently impermeable as to withstand a pressure of 3ft. head of water without the latter coming through the body of the pipe. Such pipes are unfitted for sewage drains or sewers. It often happens, however, that pipes of such a porous nature have been improperly glazed. The term "salt-glazed" is applied to indicate that the pipe has been coated to render it impermeable, which is effected by throwing in salt when the kiln is being fired. Both stoneware and earthenware pipes are salt-glazed, the glazing, when properly done, having the effect of making the pipes impermeable, which enables them to resist abra-

INSURANCE.

THE MUTUAL LIFE INSURANCE COMPANY OF NEW YORK.

PRESIDENT:
RICHARD A. McCURDY,

Policy-holders in the "Mutual" enjoy the advantages of

36, ST. MARY-AT-HILL, LONDON.
Telegraphic Address: "CARMINES, LONDON. Telephone: Avenue 5976.

sion from matter in suspension in the sewage. Stoneware pipes are usually distinguishable in colour from earthenware in that they are of a pale buff colour, while fireclay pipes are of various shades of reddy brown and sometimes grey; when struck with a hammer, a stoneware pipe has a metallic ring, which is not the case with an earthenware pipe. They may also be distinguished in the test for impermeability. The pipes should be dried until they cease to lose weight, and then submerged in water for not less than twenty-four hours. Then remove, wipe dry, and re-weigh. The best pipe is that which absorbs the least amount of water, as it will be less susceptible to the wearing action of matter present in the sewage.

1120.—SEWERS: MANHOLES ARE PART OF SEWERS.—"J. T." writes: "We are about to lay a sewer through private lands, and it is very desirable that manholes should be constructed thereon. There is some doubt whether we have power to do this, and should be glad of your opinion."

Answer.—The Local Authority may construct manholes on the sewer in private lands, as these form a part of a sewer which they are empowered under Sec. 16 of the Public Health Act, 1875, to lay, after giving the necessary notices, as required by the section. See Swanston *v.* Twickenham Local Board, 43 J. P., 380. Where the Authority require to enter the lands for examination of the sewer by means of the manholes, they may do so under Sec. 305 of the Act.

1121.—WATER SUPPLY: WATER COMPANY NOT EXCLUSIVE MONOPOLY.—"W. J." writes:—"Please inform me whether a water company having Parliamentary powers can prevent the owner of a private estate from providing and supplying the houses thereon with water at a rate to be agreed upon?"

Answer.—A water company has not the power, to the exclusion of private owners, to the supply of water in any district. There is nothing to prevent the owner in the case named from providing the supply of water to houses or other property if he so desires.

1122.—UNSOUND MEAT AND FRUIT: BOOK ON.—"W. R." writes:—"I am in want of a good cheap book on fruit (unsound, diseased, &c.), also one on meat. Would you please say which you consider the best?"

Answer.—The following books may be recommended, viz.:—Vacher's "Food Inspector's Handbook," price 2s. 6d. net, postage extra; Walley's "Practical Guide to Meat Inspection," price 10s. 6d.; Winter Blyth's "Foods: their Composition and Analyses," price 21s.; Pearmain and Moor's "Analysis of Food and Drugs," price 3s. 6d. Our correspondent will probably find the first-named book will meet his requirements, as it treats of all classes of unsound food, including fruit. Any of the books may be obtained from the Sanitary Publishing Company, 5, Fetter-lane, London, E.C.

NOTE.—A number of replies to queries are unavoidably held over.

Contracts Open.

The dates given below are the latest up to which tenders can be received.

BELFAST.—June 21st. — Extension of Sewer. — The Clerk's-office, Workhouse.

EDINBURGH. — June 22nd. — Sewers. — The Burgh engineer, 1, Parliament-square, Edinburgh.

KIRKBY-IN-ASHFIELD.—June 22nd.— Scavenging. — Mr. G. H. Hibbert, clerk, 55, West-gate, Mansfield.

KING'S LYNN, June 22nd.—Sewer.— Mr. John R. Fayers, surveyor, 8, St. Nicholas-street, Market-place, King's Lynn.

RATBY (MARKET BOSWORTH).—June 22nd.—Sewers.—Mr. W. M. Sykes, sanitary surveyor, Park-street, Market Bosworth.

SEGHILL.—June 22nd.—Removal of ashes, &c.—Mr. Thomas Spencer, clerk, Seghill, Northumberland.

DITTISHAM (DARTMOUTH)—June 23rd.—Sewer.—Mr. Edwards, Higher Dittisham.

SUTTON COLDFIELD.—June 23rd.—Sewer, &c.—Mr. C. F. Marston, A.M.I.C.E., &c., borough engineer and surveyor, Town Hall, Sutton Coldfield.

EAST ARDSLEY (YORKS). — June 27th. — Drainage WORKS.—Mr. Edward Brook, Blackgates, East Ardsley, near Wakefield.

NELSON.—June 27th. — Sewering. — Mr. B. Ball, A.M.I.C.E., borough engineer and surveyor.

GREAT BERKHAMSTEAD (HERTS). — June 29th.—Sewers, &c.—The Engineer, 9, Victoria-street, Westminster.

RUNCORN. — June 30th.—Sewerage. — Mr. William Diggle, the Council's Surveyor, Holly Bank, Frodsham.

CHARTHAM DOWNS (NEAR CANTERBURY). — June 30th.—Drainage Works, &c.—Mr. W. J. Jennings, architect, 4, St. Margaret's-street, Canterbury.

Vacancies.

ASSISTANT DRAUGHTSMAN (HARROGATE, June 23rd).—For the Town Council. Salary, 30s. per week. Mr. J. Turner Taylor, town clerk.

ASSISTANT INSPECTOR (WESTON-SUPER-MARE, July 2nd).—For the Urban District Council. Salary, £1 per week. Mr. Sydney C. Smith, clerk, Town-hall, Weston-super-Mare.

ASSISTANT WORKSHOP ENGINEER (NIGER COAST, June 20th).—For the Marine Department of the Niger Coast Protectorate. Salary, £300 per annum, rising, if engagement be made permanent, by £50 per annum to a maximum of £400. Crown Agents for the Colonies, Downing-street, London, S.W.

BUILDING INSPECTOR (LANCASTER).—For the Corporation. Wages, £2 per week. For form of application apply to the Borough Surveyor, Town Hall, Lancaster.

BUILDINGS INSPECTOR (SOUTHEND-ON-SEA, June 23rd).—For the Corporation. Salary, £104 per annum. William H. Snow, town clerk, Southend-on-Sea.

CLERK OF WORKS (STAFFORD, June 25th).—For the Guardians. Mr. William Morgan, clerk, Union Offices, Stafford.

GAS AND WATER MANAGER (BIRSTALL, June 18th). For the District Council. Salary, £120 per annum. Mr. W. Middlebrook, clerk, Birstall, near Leeds.

GASWORKS SECRETARY (HOLMFIRTH, June 24th).—Chairman, Beech House, Holmfirth.

HIGHWAY SURVEYOR, &C. (WEALDSTONE, June 20th).—For the Urban District Council. Mr. R. J. Bryant, clerk, Council Offices, Peel-road, Wealdstone, R.S.O.

INSPECTOR OF NUISANCES (ST. ALBANS, July 4th).—For the Rural District Council. Salary, £100 per annum. Mr. R. W. Brabant, clerk, Poor Law Offices, St. Albans.

SURVEYOR.—For the North-Eastern Railway Company. Salary, £400. Secretary, North-Eastern Railway Company, York.

SURVEYOR (GUISELEY, June 22nd).—For the Urban District Council. Mr. Hugh Claughton, chairman, Guiseley, near Leeds.

To Medical Officers, Surveyors, Sanitary Inspectors, &c.—High-grade Cycles at reasonable prices for prompt cash and on the GRADUAL PAYMENT SYSTEM. Catalogue post free.—MELROSE CYCLE COMPANY, Coventry.

THE

PENSION QUESTION SOLVED

How Public Health Officials may Secure a Pension in Ten, Fifteen, or Twenty Years of from £10 to £100 or more per annum.

This question is admittedly one of paramount importance to all Public Health Officials who are dependent upon their own exertions to provide for the future, and one which has for some time exercised the minds of those who are so situated. It is therefore a matter for general congratulation that a satisfactory solution of the problem has been arrived at. Those who wish for particulars are invited to fill up and return to the undersigned the subjoined form, when the fullest information will be forthcoming from a source which is highly approved and recommended by THE SANITARY RECORD.

Please inform me what Annual deposit would be required to provide a Pension of £_____ per annum in _____ years, and what sum my family would secure in the event of my decease previously; also any other investment advantages offered on my surviving.

*Name*_____

*Address*_____

_____

*Age*_____ *(nearest Birthday).*

Address—"Pension," care of Sanitary Record, 5, Fetter-lane, London, E.C.

SITUATIONS.

VACANT.

☞ *Advertisements of Situations Vacant are inserted at the rate of Sixpence per line (prepaid), minimum three lines — eight words to line. Special rates for a series.*

WANTED.

THE SANITARY RECORD *will be found an excellent medium for those who are desirous of seeking Situations in the Offices of Surveyors, Sanitary Inspectors, Sanitary Engineers, Architects, &c. The charge for such advertisements (prepaid) is Sixpence per line. Minimum three lines—eight words to the line.*

☞ Advertisements for this Department must reach us by Tuesday morning in each week, at latest.

SANITARY ASSOCIATION OF SCOTLAND.

EXAMINATIONS IN SANITARY SCIENCE.

Examinations for Certificates of Competency in Sanitary Science are held each year as follows, viz.:—In Glasgow in April, in Edinburgh in October, and at such other time and place as the Board of Examiners may determine.

Entrance Fee £2 2s.

For further particulars apply to

GEORGE MIDDLETON, M.A., LL.B.,
Writer, 92, Bath Street, Glasgow,
Secretary to the Board of Examiners.

A Stamped Addressed Envelope must accompany all letters requiring an answer.

SANITARY INSTITUTE EXAMINATIONS.

TUITION BY CORRESPONDENCE.

An Engineer and Surveyor (Mem. San. Inst.), Certificated Surveyor and Inspector, prepares students for these Exams. by Correspondence through the post.

Fees strictly moderate. Cramming studiously avoided.

The course of tuition is arranged so as not only to qualify the student for passing the exams., but what is of equal importance, viz., that he may become a thoroughly efficient Inspector.

On successfully passing the exams., all possible assistance and advice is given to help forward intending candidates for public offices.

Many of my old pupils are now filling positions with salaries of over £120 a year.

For terms, &c., address "C. E.," care SANITARY RECORD, 5, Fetter-lane, London, E.C.

SANITARY INSTITUTE EXAMINATIONS.

SPECIAL Corresponding Classes for the **Practical Sanitary Science,** and **Sanitary Inspectors' Examinations** of the **Sanitary Institute, 1898,** conducted by a gentleman holding appointments as Urban District Council Engineer and Sanitary Inspector, holder of three certificates from the Sanitary Institute, First-class Honour Medallist Hygiene, &c. Hundreds of successes.—For all particulars, testimonials, &c., apply Mem. San. Inst., Office of THE SANITARY RECORD, 5, Fetter-lane, London E.C.

OFFICIAL ADVERTISEMENTS.

CITY OF NORWICH.—The Corporation of Norwich requires an ASSISTANT INSPECTOR of NUISANCES, who must hold the Certificate of Competency in Sanitary Knowledge of the Sanitary Institute, London.

Preference will be given to one who has had practical experience.

Salary £70 per annum.

Uniform will be provided.

Applications, endorsed "Inspector of Nuisances," with three recent testimonials, to be sent to me on or before 9th July next.

GEO. B. KENNETT,
Town Clerk.

Guildhall, Norwich,
13th June, 1898.

THE ECCLESHILL URBAN DISTRICT COUNCIL require a SURVEYOR and WATER-WORKS MANAGER and INSPECTOR of NUISANCES, who will have to devote the whole of his time to the duties of the offices.

Salary £130 per annum for the combined offices.

The selected candidate will be required to commence his duties forthwith upon appointment, and to reside within the district.

Candidates must be between the ages of 25 and 40 years.

Applications, stating age and experience, should be made by letter, addressed to the undersigned, and marked outside "Surveyor," not later than Monday, June 27th, 1898, accompanied by recent testimonials, not more than three in number.

JOS. RICHARDSON,
Solicitor and Clerk to the Council.

Eccleshill, near Bradford.

THE

Sanitary Record,

JUNE 24, 1898.

A WELL-MERITED REBUKE.

We are not very much concerned as to what were the feelings of those members of St. George's, Southwark, who have so persistently refused to listen to their own Medical Officer, when they heard that a communication had been received from the Home Secretary with reference to the crypt of St. George's. Acting on the report of the Chief Inspector of Burial Grounds, Sir Matthew Ridley has issued a notice ordering the removal of the human remains from underneath the church. The Vestry has nothing but its own wilfulness and obstinacy to thank for this rebuke. But we do rejoice that the highest administrative Authority in the kingdom has upheld a conscientious and painstaking officer in the performance of his duty. We heartily congratulate Dr. Waldo on the complete vindication of his conduct. Had the Vestry listened to him at the outset all this friction with Whitehall might have been prevented, and the special circumstances of the case might have secured for Southwark a generous consideration in quarters where help could have been given.

Dr. Waldo is filling a most difficult position. The district he serves is an exceptionally crowded one; small tenements abound, and for generations the owners and lessees have done little more than gather in their exorbitant rents. When Dr. Waldo entered upon his duties he found a death-rate equal to any, and far above most, of the districts in the metropolis, and he resolved to do his utmost to change so undesirable a record. He marked out the foulest dens; he made a complete tour of the district, and noted the spots where even the elementary requirements of sanitation were unknown. Armed with these facts, he went before his Vestry and invited it to take action. But he found himself thwarted on every hand. The consideration of his reports was burked, or constant adjournments were made. Attempts have been made to edit his reports, but they have failed; and a less earnest and persistent officer would have thrown up the task long ago.

But in every point that Dr. Waldo has been resisted by the Vestry he has been upheld by the central Authority. Still he has ever been generous to those who have been his most bitter opponents, and never turned to rend them in the hour of victory, thus proving that he is no mere seeker after notoriety, but a conscientious public officer. To such men as this our country owes a debt of gratitude. They place their duty to the community far above the mere favour of interested individuals. It is for this reason that we rejoice in the vindication of Southwark's Medical Officer, and that the Vestry has again been taught that its duty is to look after the welfare of its constituents, and not waste its time in attacking its officials.

Notes.

Last Tuesday at the County Council.

The meeting of the London County Council on Tuesday last was of more than ordinary interest. Yet another proposal was put forth for opening up a new channel of communication between Holborn and the Strand. Let us hope this will be the final attempt, and that not only will the Council approve of it, but that it may pass through Parliament next session, and in a year or so become an accomplished fact. The estimated cost of the new scheme is not so high as its predecessors, but it appears to be quite as efficient. The other recommendation receiving most attention was contained

in the report of the Local Government and Local Taxation Committee, in which the Council was asked to adopt a series of new bye-laws. An end is to be put to the nuisances of the streets. The inhabitants of private thoroughfares will be particularly thankful for this, as these have been the "happy hunting ground" of the vendor of sensational news—real or imaginary. The organ-grinding affliction will still have to be endured, unless the householder will have the courage to have its exponent "moved on." But the owners of "miserable curs" and of "crowing cocks" must beware, for under the new bye-laws these must be silenced or removed to more open and congenial neighbourhoods. After all, we may yet know what it is to have quietness in the streets of London.

An Economical Sewerage System.

At a time when so much is being written about "new" sewerage schemes and systems, it is well for us to know what has really been accomplished. The history of the Winsford experiment may be familiar to many of our readers, but to a large circle of sanitarians the article appearing in last week's *Engineer* will come as a surprise. It is a plain unvarnished story of what may be done by making use of the material at hand instead of sighing for something miles away. Winsford is in the centre of the salt industry, and from the various factories is given out vast quantities of "cinders, basses, clinkers, and ashes." When twenty years ago the newly-formed Local Board found itself called upon to provide a sewerage system for two villages with 12,000 inhabitants, it was fortunate in having an engineer who saw in this "rubbish" just the material for the task. The article goes on to show how filter beds were constructed near the banks of the river Weaver, how these are worked alternately, and how the process of purification proceeds "intermittently and almost automatically," with a result that, although the effluent flows directly into the river, "the bright, clear water of the Weaver along the edge of the cinders affords not the slightest trace of discoloration or pollution." Happy Winsford, what would many a larger place give for such a record. And the cost? Why £300 covered the outlay on the filtration works, and £50 per annum keeps them in working order. This contribution to the drainage discussion is very timely. We do not say it is possible for every place to obtain so satisfactory a result at so low a price; but it does prove that, if we will only allow nature to help science, "economical sewage disposal" is something more than an "ideal"—it is a fact.

The "Low Flash" to be Maintained.

Forecasts of the report of the Petroleum Committee have been pretty numerous within the last week, but generally they agree that there will be no recommendation to increase the flashing point of ordinary petroleum. It would appear that those who have been blaming the oil for so many explosions and fires have been upon the wrong track. "It's not the oil at all, at all." It's the lamps that have been at fault; at least, that is what must be inferred from the finding and recommendation of the Committee. Might not the man who gets drunk say with almost as much reason, "Shure, and it's not the liquor at all that did it; begorra, it was the pot that held it!" No, Mr. Collings, it won't do. The British public knows that explosions occur to low-flash oil, and that this source of danger in their homes will be removed if the standard is raised. The question of "cheapness" is beside the mark. The first point for the Government to consider is the safety of its subjects, and if the Committee had confined their attention to that, the result of its deliberations might have been different. The *Star* deserves every credit for the way it has brought this important question to the front.

The Camberwell Dust.

Thanks to the enterprise and energy of its Clerk, the Camberwell Vestry has saved itself from the threatened action of the London County Council. The story of how this was accomplished was told at the meeting of the Vestry on Wednesday week. Instead of wasting time and money in fencing with the County Council, the Clerk had gone direct to headquarters and frankly admitted the justice of the charge preferred—that a proper collection of house refuse did not take place in the district. He then asked for time, and "undertook that if this was granted he would see that immediate measures should be taken to ensure the efficient carrying out of the Council's bye-laws," and then it was shown that in the course of a few days, with a little re-arrangement of the Works Department, the weekly removal of dust had been accomplished. But what a pity the Vestry had not taken this common-sense step before, instead of "dilly-dallying" for eighteen months, and running the risk of losing a substantial contribution from the Equalisation Fund, besides being involved in a costly lawsuit. It is difficult to find out the reason for this "folly," unless it is that the Vestry deemed itself wiser than its Surveyor, who urged it to comply with the rules of the County Council. We believe his recommendations were rejected on the ground of "economy." But to break the law is always a dear process, and we think Camberwell will, when its next rate is made, find this out to its cost.

"Yellow Jack" Circumvented.

The *Pall Mall Gazette* is responsible for an important item of news from Rome. We are told that a young Italian doctor has discovered a remedy and preventive for yellow fever. If this be true, the value of the discovery cannot be overestimated, and Italy may well be proud of its clever young medico. Dr. Sanarelli, who is but thirty-four years of age, spent the early part of his professional career at Pavia; from thence he went to Munich, finishing his training under Pasteur in Paris. Thus prepared, he went out to Uruguay to found an Institute of Hygiene at Montevideo. What he has experienced during the last three years we will let him tell in his own words:—"I started," he said, "with the intention of devoting my whole energies to yellow fever, so on my arrival at Montevideo I shut myself up on the Isle of Flores, where there is a lazarette. There I followed the course of the disease from the beginning to the usually fatal end,

trying to find the terrible microbe. The first results were most discouraging, but finally, in the blood of a still living man, I found a characteristic micro-organism, present in great quantities in the body. After long and laborious research, I produced a powerful toxine, which, in animals, produced all the phenomenon of yellow fever. With human beings the result was extraordinary. Brazil at once begged me to go to the State of San Paulo, so I left with a scientific commission for San Carlo do Pinhal. This city, at one time containing 27,000 inhabitants, to-day reduced to 1000, is a most potent centre of infection. It is a city of empty houses and deserted streets, the few inhabitants all dying or convalescent. The mortality in the hospitals had been 87 and even 90 per cent.; with the toxine it was reduced to 27 per cent. We tried the cure in the gaols with great success. Formerly, when one case in the prisons or barracks broke out all the prisoners contracted the disease. During my sojourn at San Carlo do Pinhal a prisoner died; the others were at once injected with serum, and not one had it. The people really give me more credit than is my due. They seem crazy with joy, but it is a reprieve from death for a very large proportion of the population. The origin of the bacillus is heat and damp. It is in the air, and so very much more difficult to reach. The difficulty at present is to obtain sufficient serum, but I hope that difficulty will soon be overcome."

Acetylene Gas for Towns.

At a time when there seems to be a revolution in the lighting arrangements of our streets, the exhibition of acetylene gas apparatus at the Imperial Institute may be the means of making some public bodies think whether after all it is necessary to rush into the extremely expensive luxury of electric lighting. Especially is this the case with regard to villages and small towns. A glance at the exhibits at the Institute shows that in acetylene we have an agent capable of providing a brilliant light at a much lower cost than it is possible to produce coal gas in such places. For instance, the Manchester Acetylene Company has, we understand, a contract in hand to provide a town in Banffshire with light at a cost of what is equivalent to 3s. 4d. per 1000 cubic feet of coal gas, against 8s. 4d. per 1000, the price at present paid. It is only fair to say that the old pipes and mains are being utilised. As the manufacture of this gas developes, we have no doubt the production of carbide of calcium will be still further increased, and the price correspondingly reduced. And in this may be found the agent for cheaply lighting the semi-rural parts of the country.

The Vaccination Bill in Committee.

A good start was made last week with the Committee stage of the Vaccination Bill, and several important amendments were disposed of. The first of these was a proposal to limit the operation of the Act to three years, on the ground that its compulsory character was confessedly rested on the discovery of glycerinated lymph, a discovery which, it was pointed out, had yet to await the test of time, and could not at present be regarded as other than experimental. It was a specious argument, and enlisted considerable support, but the Government stuck to their guns, and the amendment was thrown out. Sir Charles Dalrymple, who is now the only survivor in Parliament of the Royal Commission, probably gauged the character of the amendment correctly, when he declared that it was in reality a disguised form of attack on the Bill itself. Another amendment which shared the same fate was one proposed by Mr. Gedge, providing for the payment of a small fee—a shilling or so—to every parent bringing a child to the public vaccinator. We believe that some such system prevails in France, its object, of course, being to disarm opposition to vaccination; but it is open to doubt how it would work in this country, and whether it would really effect the end aimed at.

Alteration of the Age Limit.

The most important decision, however, arrived at by the Committee was the alteration of the age limit from twelve months, as proposed by the Bill, to six months, which is the age prevalent in Scotland. Mr. Chaplin has before this pretty clearly indicated his preference for the higher age, but he had to give way to the arguments with which he was assailed, and especially in view of the fact that both the medical members, Sir Walter Foster and Sir William Priestley, were ranged against him. The great argument for the six months' age is, of course, the experience of Scotland, where it is known to be a success, whereas there is no such guide in regard to a twelve months' limit. Then, again, uniformity is much to be desired, and there is no reason in the world why the practice should vary in different parts of the kingdom. And, finally, to clinch matters, experience has shown that the longer the age is deferred the more difficult does it become for the vaccination officers to trace children. Already the proportion of unaccounted for cases is far larger than it should be, and as it is quite certain that it will increase with the extension of the age limit, it is desirable not to extend the limit more than is necessary.

The Honour to Lord Lister.

Edinburgh, the seat of one of the most famous medical schools of the world, has conferred a signal honour—the highest in its power to confer—on one of the most eminent surgeons of our time. In bestowing on Lord Lister the freedom of the city, our "Modern Athens" marked its high sense of the inestimable benefits he has conferred on medical science and on humanity by his discoveries in connection with antiseptic surgery. He is able to recall the time, at the commencement of his career, "when every operation was attended by terrible pain and fearful danger." To Sir James Simpson, also an Edinburgh professor, we owe the elimination of pain from surgical operations by means of anæsthetics; to Lord Lister is due the distinction of having been the first to apply to surgery the antiseptics which have removed the subsequent danger. By these two great discoveries surgical science has been revolutionised, so that now operations are successfully performed which would have been deemed

impossible in an earlier age. Surely the highest glory that any human being can achieve is to have been the instrument of saving life and diminishing the sum of human suffering; and no man has a higher claim to that distinction than Lord Lister.

Munificent Gift to Edinburgh University.

A very handsome gift by a donor whose name has not yet been disclosed has been made to the University of Edinburgh. This unknown benefactor has intimated his intention of giving such a sum, not exceeding £10,000, as may be necessary to build and equip a laboratory and class-room to be used exclusively for the teaching of public health, in connection with the chair on that subject which is about to be established in the University. The University is to provide the site for the proposed building. It is a princely and a most practical gift, and in acknowledging it the University Court has expressed its gratification that the gift has taken a form which enables the University to extend its usefulness by the provision of an institute which is urgently required for promoting the study of public health. It is hardly necessary to point out what an immense gain the new laboratory will be in connection with practical instruction in sanitation. If all our Universities were similarly endowed, the scientific study of hygiene would receive a stimulus that it is not easy to estimate. Under present conditions, in many centres of instruction, the tendency is for students to be imbued with merely theoretical knowledge, whereas there is no subject that requires practical illustration, in order to its intelligent apprehension, more than sanitary science.

Tenure of Office of Public Health Servants.

It will be interesting to Public Health officials to know that the Urban Clerks' Association, whose offices are at 22, Great George-street, Westminster, S.W., are promoting a Bill in Parliament, the object of which is to secure to the officers of District Councils the same security with regard to the tenure of their offices as is now enjoyed by the officers of Poor Law Unions, namely, that they may not be dismissed without the sanction of the Local Government Board, and on reasonable cause shown. We sincerely hope that such a Bill may become law, for it is, in our opinion, little less than a blot upon sanitary administration that officers of Sanitary Authorities, who in the very nature of things, if they carry out their duties in a proper spirit, must come in conflict with some of the members of the Authority who employ him. We know, unfortunately, of too many cases where local builders obtain seats on Urban and Rural Councils for the express purpose of clogging the wheels of sanitary progress, and checking the action of sanitary officials, and where zealous officers have been compelled to resign their appointments owing to the persecution of this class of member, and we have a case at the present moment where an official holding the combined office of surveyor and inspector, has been served with notice to terminate his appointment owing to his advocacy of the necessity of Building Bye-laws being framed and enforced to regulate new buildings. The jerry-builders were a force on this particular Council, and their clamour that the cost of buildings would be increased if building bye-laws were put in force, outweighed all considerations of the health and comfort of the future inhabitants. Such action is a disgrace to any Sanitary Authority, and also a blot on our system of public health administration. We cordially wish the Bill success.

Plague Spots.

An extraordinary report has been issued by Dr. Bates, the Medical Officer of Health for Bethnal Green, as to the exceedingly unsanitary condition of the tenements in that district. In Faith-street, in Cambridge-road, overcrowding prevails to a startling extent, and in many instances the rooms are too damp to sleep in. Consequently the poor folks are compelled to herd together in one or two rooms "like herrings in a barrel." Out of 47 houses in Pitt-street occupied by 259 persons, 27 are unfit for human habitation, and 11 out of 12 houses in Lucas-street have been condemned. Medical officers who do not shirk their work expose these plague spots, and it is the duty of Vestries to stamp them out altogether. To permit such inhabitable places to remain any longer would be detrimental to the health of any neighbourhood.

The Pay of the Nurses.

We observe from the *Bombay Gazette* that much dissatisfaction has been caused by the treatment that certain of the nurses sent out to India by the Secretary of State has received at the hands of the Government. Their pay for the month of March, as agreed on by the Secretary of State, was to have been 175 rupees; but when matters came to be settled, a number of deductions were made—representing certain advances, boarding charges on their arrival from home, and before they were provided with free quarters at the hospital, and charges by the Committee's contractor for the supply of food—that brought the balance due to these nurses, after a month of hard work, down to about four rupees! The deductions were made under the authority of the Accountant-General, and seem to have been partly due to red-tapeism; for though the individual members of the Plague Committee felt the result to be little short of scandalous, they appear to have been without authority to grant any concession without official sanction. Part of the boarding charges, it is true, were subsequently refunded; but even so, the remuneration received was miserably inadequate for the services of these brave women. It is to be hoped that "someone had blundered," and that the blunder has been, or will be, rectified; for assuredly the Government cannot expect nurses to undergo the self-sacrifice entailed in plague duty if they are to receive such scurvy treatment.

We beg to draw the attention of our readers to the announcement of Mr. Hamblett in our advertisement pages. He has decided to convert his well-known business into a limited liability company. The blue bricks manufactured by this firm are celebrated all the world over, and investors have an opportunity of becoming interested in what appears to us to be a sound and progressive firm.

THE CHEMICAL AND BIOLOGICAL ANALYSIS OF WATER.

By T. H. Pearmain and C. G. Moor, M.A. (Cantab).

Members of the Society of Public Analysts. Authors of "Applied Bacteriology;" "The Analysis of Food and Drugs," &c.

(*Continued from page* 641.)

TOTAL HARDNESS.

In making tests a stoppered bottle holding about 150 c.c. should be used, and the soap solution is added at about the rate of 2 c.c. for each successive addition, and when the liquid shows signs of lathering, the bottle should be laid on its side, and the lather should last as nearly as possible two minutes. Great care should be taken not to mistake the peculiar scum yielded by magnesium salts for the typical soap lather.

PERMANENT HARDNESS.

If the "total hardness" exceeds ten grains per gallon, it is advisable to see whether it is due chiefly to carbonate of calcium (temporary hardness) or to the sulphates and chlorides of magnesium and calcium (permanent hardness). This is done by boiling 70 c.c. of the sample down to about 40 c.c., when the chalk will be precipitated; the liquid is then made up to 70 c.c. and tested with the soap solution, as mentioned above.

HEHNER'S METHOD FOR THE ESTIMATION OF HARDNESS.

In this process, the calcium and magnesium carbonates, which cause the temporary hardness, are first determined by titration with standard acid. Both the carbonates and sulphates of calcium and magnesium are then precipitated by adding a known volume of standard sodium carbonate solution in excess and boiling for half an hour. The unchanged sodium carbonate is then estimated by means of standard acid. The amount of sodium carbonate which is decomposed by the above sulphates is thus found, and from this the permanent hardness can be calculated.

Temporary hardness.—70 c.c. of the sample is made hot in a dish and then titrated with $\frac{N}{50}H_2SO_4$ using phenoacetoline 0·2 per cent. solution as indicator. Each cubic centimetre of acid used is equivalent to one grain per gallon of $CaCO_3$.

Permanent hardness.—Take 70 c.c. of sample and add about as many cubic centimetres of $\frac{N}{50}$ Na_2Co_3 solution as there are grains per gallon of non-volatile solids. Transfer to a platinum dish and evaporate to dryness on a water bath. Take up with recently boiled distilled water, which must be quite cold, then filter, wash residue well, and make filtrate up to about 70 c.c. This is raised to boiling point and titrated with $\frac{N}{50}$ H_2SO_4, using phenoacetoline as indicator. The number of cubic centimetres of acid used deducted from number of cubic centimetres of $\frac{N}{50}$ Na_2CO_3 used, equals grains per gallon of permanent hardness.

The total hardness is obtained by adding the sum of the permanent and temporary hardness.

It is of interest to note that each degree of hardness represents a soap-destroying power equivalent to 2½ oz. of soap per 100 gallons of water.

A greater hardness than 30 parts per 100,000 is undesirable from the hygienic standpoint. The higher the ratio of "temporary" to "permanent" hardness the better. The hardness of waters may be classed as follows:—

Very soft	3 to 5	parts per	100,000
Moderate	5 to 10	,,	,,
Hard ...	10 to 30	,,	,,
Very hard	above 30	,,	,,

For successful brewing purposes waters containing large amounts of "permanent" hardness are valued. In the brewing of light ales the sulphate of calcium tends to keep out the colouring matters of the malt. The water of Burton-on-Trent contains from 28 deg. to 30 deg. of permanent hardness.

PHOSPHATES IN WATER.

Phosphates in water can in most cases be only of sewage origin. Absence of phosphates, however, is no proof that the water is free from sewage pollution, since substance like iron and alumina, which are present in all soils precipitate phosphoric acid; and plants derive their phosphorus from it, and thus remove it from the soil.

As small a quantity as ·0005 of a gramme of calcium phosphate will yield a yellowish turbidity with ammonium nitrate and ammonium molybdate, so that any appreciable quantity would be detected by treating the ignited total solids with the least possible quantity of nitric acid, neutralising with ammonia, evaporating the filtered liquid in a porcelain dish to a bulk of ·5 of a centimetre, adding a drop of strong nitric acid and a few drops of 10 per cent. solution of ammonium molybdate, and warming the whole to 60 deg. Cent. If it is desired to estimate the amount present, 1000 c.c. of the water should be evaporated and the same procedure carried out, the precipitate collected on a small filter, washed with spirit and ether and dried, when the weight obtained multiplied by ·0373 will give the result as P_2O_5.

O. Hehner (*Analyst* 5, 135) published determinations of the phosphoric acid in a number of different waters. He concludes that when the phosphoric acid is above ·5 parts per million the water should be regarded with suspicion, but that the absence of phosphoric acid is not a positive proof of freedom from pollution, as some waters known to be polluted, when examined by him, contained very little or none.

J. West-Knights (*Analyst* 5, 180) has described a colorimetric process for the estimation of P_2O_5 in waters, which he verified by comparison with the gravimetric process.

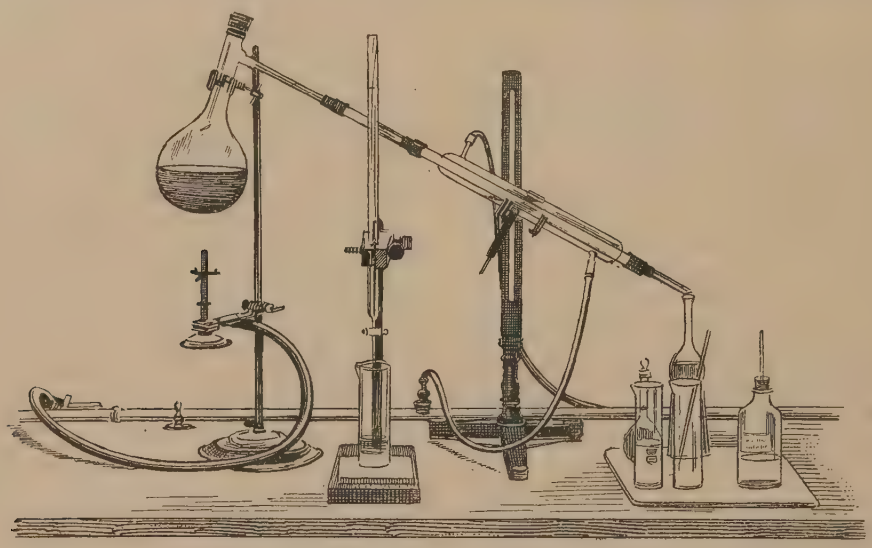
Sidney Harvey, in the same number of the *Analyst*, gives results obtained on an old well, which had been closed for some time, situated near an ancient churchyard. He found as much as five grains of nitrates and one grain of phosphoric acid per gallon.

POISONOUS METALS.

The metals which we have occasionally to seek for in water are lead, copper, and iron.

These are usually tested for by placing 100 c.c. of the water to be tested in a nessler glass, and passing a slow current of sulphuretted hydrogen through it, having previously added a single drop of

strong hydrochloric acid. If a dark cloud forms it must be due to one of these three metals, and we may either proceed by concentrating the water, or we may at once test for lead by adding potassium bichromate or potassium iodide. In both cases a yellow cloud will form after an interval. If lead is present, about 1-50th of a grain per gallon (2·8 parts per million) can be detected in this manner. An approximate estimation of lead in water can be made by comparing the tint produced on passing sulphuretted hydrogen gas into 100 c.c. of the sample, and then making up a tint to correspond with it, by adding so many centimetres of a standard solution of lead acetate to 100 c.c. of distilled water in another nessler glass and passing the gas through it. This method is satisfactory for all potable waters; but in the case of aërated waters containing vegetable acids, sugar, or organic matter, it is advisable to adopt the method described by Dr. F. L. Teed (*Analyst*, vol. xvii., 142).



Apparatus used in Wanklyn's Process.

Those substances which would cause the reduction of potassium bichromate do not interfere with the production of lead sulphide, and Dr. Teed's process also provides against the precipitation of copper and iron, both of which may be present in small quantities in aërated beverages. He proceeds as follows:—

The liquid to be tested is placed in a nessler glass, and a few c.c. of ammonia and a little potassium cyanide added, and then a small quantity of ammonium sulphide. Any coloration then produced is due to lead alone, copper and iron not interfering. The lead sometimes found in aërated waters may be due to the metal work in the case of syphons, but is apparently sometimes due to the action of the liquid on the glass. When such beverages (soda-water, ginger-beer, lemonade) are examined under the Food and Drugs Act, it is essential that three bottles should be purchased and opened, their contents mixed in a jug in the presence of the vendor, and then poured back into the bottles and sealed up.

In testing aërated, and, indeed, ordinary potable water for lead, it is well to confirm its presence by the bichromate test, which must in the case of beverages be performed after the destruction of the organic matter present, by evaporating in a porcelain dish and igniting very gently with a drop or two of strong nitric acid to destroy carbon. The residue is then taken up with water, and a few drops of nitric acid and potassium bichromate added. A comparison can then be instituted, using a standard lead acetate solution treated in the same way.

Copper is not found in natural waters in this country, except possibly in the neighbourhood of copper lodes, but is common in some countries—for example, Barbadoes.

It is a disputed point how far copper is a dangerous poison in small quantities, and it is a more common constituent of many foods (such as wheat, cocoa, oysters, &c.) than is generally supposed.

It is probable that copper is less dangerous than lead, but no water should be passed as satisfactory which contains as much as one-fiftieth of a grain of the metal per gallon.

The power of certain waters to attack lead is considerable, and while very soft waters are most notable for their plumbo-solvency, there are several causes which conduce to the action of water on lead.

Pure water, *e.g.* distilled water, has a decided action on lead, particularly if the lead is sometimes exposed to air, as might be the case in an intermittent service. This action is prevented if even small quantities of calcium salts and silica are present. Again, the presence of large quantities of nitrates or of chlorides is said to give water the power of acting on lead.

Probably the presence of a large quantity of carbonic acid and of vegetable acids, such as occur in a surface water collected in moorland districts where peat abounds, is the most important cause of plumbo-solvency. In such waters it is likely to be found that the action is greatest in the autumn, when the decaying vegetation imparts a greater quantity of carbonic acids and vegetable acids to the water than at other times of the year.

Many widespread outbreaks of lead-poisoning have occurred in the past in districts supplied with moorland surface waters, but the reported cases have very greatly diminished of late years as the lead pipes were gradually replaced by tin, tin-lined lead pipes, or iron pipes. Probably the best pipe is that known as the "Health Pipe," which is an iron pipe lined with tin.

A valuable and detailed examination into the causes of plumbo-solvency was carried out by Dr. Power, Dr. Houston, and others, at Settle, and will be found in the Medical Officer's Report, 1893—1894, Local Government Reports. In their investigations a very important point was clearly shown, namely, that the plumbo-solvency of a water collected from a peaty ground is influenced largely by the length of time the water stands in peat, if the water sinks into the ground and reappears again in the form of springs it loses its power of action on lead, whereas that water which drains away from water-logged peat acts on lead in a marked manner.

An outbreak of lead-poisoning in Sheffield, which is supplied with a water from a moorland collecting ground, was successfully dealt with by artificially hardening the water by passing it over limestone; this plan is still in operation and has since been adopted elsewhere.

In the investigation above referred to, Dr. Houston succeeded in isolating from peat infusion two bacteria, which he has baptised "O" and "Q" which when grown in peaty water produce a considerable degree of acidity and cause the water to act on lead. As regards the quantity of lead that should be permitted in drinking water, the facts that lead is a cumulative poison and that the plumbo-solvency of a water will probably vary with the season, point very strongly against the advisability of passing a water containing even the smallest traces. Phosphate of lead is very insoluble, so that if water containing lead is passed through an animal charcoal filter (which, of course, contains calcium phosphate) all lead will be removed from the water.

DETERMINATION OF ORGANIC MATTER.

The determination of the organic matter—that is to say, the extent of the animal or vegetable pollution—is the most important factor in the sanitary analysis of water.

The three most important processes in use for the determination of the organic impurity in water are the following:—

(*a*) The free and albuminoid ammonia process.
(*b*) The moist combustion or oxygen "consumed" process.
(*c*) The combustion process of Frankland and Armstrong.

The combustion process of Frankland, although a very ingenious process, is not in very frequent use, owing to the fact that it requires very elaborate apparatus and is unfortunately liable to numerous sources of error even in practised hands.

THE FREE AND ALBUMINOID AMMONIA PROCESS.

This process was devised by Wanklyn and Chapman in the year 1867, and is now in use by water analysts all over the world. The object of this process is to obtain an indication of first the amount of organic matter in a given water, by estimating the amount of free or saline ammonia, and secondly determining the "albuminoid" ammonia by boiling with a strongly alkaline solution of potassium permanganate. This decomposes the organic matter present in the water with the evolution of a further quantity of free ammonia.

ESTIMATION OF FREE OR SALINE AMMONIA.

The process is usually worked as follows:—500 c.c. of the water to be examined are placed in a retort or flask capable of holding at least 1200 c.c. and connected to a Liebig's condenser.

A side tube flask is preferable to a retort, as it is far more difficult for splashings to pass into the distillate than in the case of a retort.

A small quantity of sodium carbonate (about half a grain) is added to the water to ensure the liberation of any ammonia that may be present as chloride, sulphate, nitrate, or any other non-volatile salt. Sometimes this addition is not necessary, owing to the water being slightly alkaline naturally, but it is preferable not to omit it in any case. It is customary to distil over one-tenth, that is, 50 c.c., into a Nessler glass which has previously been rinsed with ammonia-free water. As a matter of experience, it is found that in the case of most waters three-quarters of the total saline ammonia will be present in the first tenth, and it is therefore customary to add on one-third of the ammonia found in the first cylinder, and to take this as representing the whole saline ammonia rather than to nesslerise the succeeding distillates.

(To be continued).

LIME, MORTAR, AND CEMENT: THEIR COMPOSITION AND ANALYSES.

By W. J. DIBDIN, F.I.C., F.C.S., &c.

CHAPTER V.

(*Continued from page* 616.)

The appended tables, Nos. IV. to VII., contain the results of the analyses of some typical samples.

Table No. IV. shows the results of the analyses of five samples of cement mortar.

Table No. V. shows the results of the analyses of three samples of bad mortar.

Table No. VI. shows the results of partial analyses of fifteen samples of very bad mortar; in these the analyses were carried only far enough to show that all the samples contain excessive quantities of earthy matter and old mortar; and also that they were deficient in freshly-burnt lime.

In contrast with these, Table No. VII. shows the result of the partial analyses of a sample of good mortar taken from a public building in course of erection. In all the following tables the results are stated in percentages.

The average total lime in cement may be taken as 60 per cent.; therefore, the lime found, including that carbonated, may be corrected to volume of cement thus:—Sample No. 1—CaO = 11·8 + 1·6 carbonated = 13·4 = 22·3 of cement; add one-eighth for correction to volume = 25·1 vols. of cement to 67·34 of sand, or a ratio of 1 : 2·7.

TABLE IV.

Analyses of Samples of Cement Mortar.

	No. 1.	No. 2.	No. 3.	No. 4.	No. 5.
Moisture, water of hydration, &c. ...	7·50	6·12	7·72	7·26	9·68
Lime (CaO)	11·80	10·87	11·97	9·20	11·24
„ carbonate ...	2·86	2·86	1·04	1·87	1·45
„ sulphate ...	0·20	0·30	0·99	0·84	0·71
Iron oxide and alumina	4·35	3·75	4·00	4·95	4·00

TABLE VII.

Sample of Good Mortar taken from a Public Building in Course of Erection.

Moisture	17·84
Lime (CaO)	14·43
Lime carbonate	0·97
Sand, grit, &c.	59·15
Earthy matter	1·05
Iron oxide, alumina, and soluble silica	3·75

Commercial lime (of 80 per cent. CaO) to sand, grit, &c., by volume, 1 to 2·6.

Commercial lime (of 80 per cent. CaO) to all other matters (dry), 1 to 3·0.

In opening the discussion which followed the reading of the paper,—

Sir Charles A. Cameron said he was afraid he could not add anything to the very valuable information that had been laid before the Society by the authors of this paper. He occasionally had specimens of cement submitted to him which, although apparently having a correct composition —according to what was laid down in the text-books—nevertheless would not adhere to the sur-

face of bricks. As a matter of fact, disputes were constantly arising in connection with cement, mortar, and concrete, and there was a very large field open to workers in the direction of obtaining information which would enable such disputes to be settled on a scientific basis. In Ireland he did not think it was customary to use ground bricks in place of sand to such an extent as appeared to be the case in England. He believed the authors had mentioned the case of a mortar in which the proportion of lime to sand was as low as 1 : 9. He had himself once examined a sample containing almost as much sand, viz., 86 per cent.

Mr. Allen said that one problem which he had been called upon to solve was how much road-sweepings a particular sample of mortar contained, and what was the proportion of "clean, sharp sand." Road-sweepings seemed to be a very indefinite article, and he thought that if the authors could indicate how to ascertain the quantity present, it would be of great service to others as well as to himself. It seemed to him, if he had understood that part of the paper correctly, that it was a little questionable whether it was fair to deduce the amount of cement in a cement mortar from the amount of soluble silica. This surely must be a very variable quantity. There was no doubt that the Society was very much indebted to anyone bringing forward figures on such a difficult subject, as they would at least afford something like a basis for further investigations.

Mr. Bodmer remarked that where broken bricks were used in substitution for sand, the bye-laws, although providing for the proper grinding up of the bricks, did not specify distinctly that they should be well burnt. Badly-burnt bricks might be used, and in that case the amount of earthy matter present would be considerable. He thought it desirable that either the use of bricks should be altogether prohibited, or that some more definite limit should be laid down as to their employment.

The proportion of quicklime contained in the lime used was also a matter upon which disputes often arose, but it was hardly possible to suggest any definite standard, for in some kinds of lime which were really very good for mortar making the percentage of actual quicklime was comparatively low.

(To be continued.)

THE SANITARY INSTITUTE.

At an examination in Practical Sanitary Science, held in Leeds on June 10th and 11th, 1898, one candidate presented himself. At an examination for Sanitary Inspectors held in Leeds on June 10th and 11th, 1898, thirty-six candidates presented themselves. The following twenty candidates were certified, as regards their sanitary knowledge, competent to discharge the duties of Inspectors of Nuisances :—Edwin Ainley, John Robert Bell, Tom Biker, George Henry Canby, Edwin Carratt, James Coupe, James Samuel Cromack, Arthur George Dalziel, John Finn, Frederick William Girven, Joseph Jackson, William Thomas Jelfs, Henry King, John William King, Augustus Henry Merryman, Miss Lizzie Marguerite O'Kell, Robert Claybourn Schofield, George Scott, jun., George Siddall, and Alfred Wharfe.

"HALF-TIMERS."

Mr. Waddington, the retiring President of the National Union of Teachers, took for the subject of his address last Easter the question of half time, and exposed in no measured terms the hollowness of the pretexts put forward by its defenders, the conscious or unconscious spokesmen of the parents, whose selfish greed was, he maintained, the true motive and that on which the whole system rested. He showed how the Elementary Education Act required every child to attend school between the ages of five and fourteen years, a recent amending Act having abolished all fees for the period of compulsory attendance. But the Education Department had sanctioned bye-laws which overrode and defeated the intentions of the Act. In 70 per cent. of the school districts a child could obtain total exemption at the age of eleven by passing as low a standard as the fourth ; at twelve a boy might be made to work full time underground as a miner, though he was not allowed to pick coal above ground until a year later.

Only one-fourth of the children in our schools were over eleven years of age, half a million of the population between eleven and fourteen having left school just at the age when they were beginning to derive permanent benefit from the instruction they were receiving, but when what they had already learnt, if not impressed by continued training, rapidly faded from their memories. Of those who did remain 120,000 were half-timers, of whom more than half were in Lancashire, and fully three-fourths in that and the adjoining county of Yorkshire. As headmaster of St. James' National Schools, at Bolton, Mr. Waddington, spoke with the authority based on personal knowledge ; he denounced, as dishonest pretences, the various pleas put forward in extenuation of child labour, especially in the factory, the mill and the mine, as that it was necessary for the acquisition of manual dexterity, that it had either physically or intellectually any educational value, that the prosperity of the textile and other industries was bound up with it, and that the earnings of the children were necessary to keep the wolf from the door. Were, he asked, all the 66,508 half-timers in the schools of Lancashire the children of poor widows dependent on their scanty earnings of half a crown a week ? The employers, he maintained, were not to any considerable extent the supporters of child labour. It was the operative who wanted an eight hours day for himself who insisted on sending his children to the mill, or, if there were no room for them there, to work elsewhere, that he might reap the fruits of their toil ; the operatives of Burnley and Blackburn, continually on strike because of the unwholesome atmosphere of the mills, who condemned their little children to work under conditions they deemed, perhaps rightly, deleterious to their own health, and as the *Schoolmaster*, in an able report on the subject some two or three years ago, showed by quoting resolutions passed by the trades unions at different meetings, urged at one time the unhealthy conditions of the high temperature and humidity of the rooms as an argument for shorter hours for themselves, and at another maintained that factory work was conducive to the health and well-being of the young. But though the material side of the question was that alone with which

legislation could deal, there was also a social aspect on which Mr. Waddington, as a teacher, felt very strongly, viz., the entire withdrawal of the child from the influence of home and school. He did not suggest that there was a lower standard of morals among the great body of mill hands than among others in the same grade of society, but he did maintain that the tone, the moral atmosphere of the factory, was not conducive to the normal development of character in the young; the teacher found that half-timers had lost the fresh simplicity of childhood, they were no longer amenable to influence, but were precocious and bold, and had adopted the ways, the thoughts, and language of adults, and of those of by no means the most desirable class. The whole system was in his opinion "bad, barbarous, and an anachronism, without even the excuse of necessity."

From whatever standpoint we approach the question, whether on the physical, moral, social, or educational aspect, we heartily agree with every opinion expressed by Mr. Waddington, and must confess to a feeling of shame when we call to mind the position taken by the representatives of this country at the Berlin conference convened by the German Emperor, when Sir J. Gorst promised in good faith on behalf of England that the resolutions subscribed to by all the delegates present, except those of Italy and Spain, should be honestly carried out, and see now that while France, Switzerland, and others have been true to their word, and Germany has gone even further, England alone has as yet made no move towards the abolition of child labour.

SANITARY WATER ANALYSES.*

By FLOYD DAVIS.

(*Concluded from page* 598.)

THE CHEMICAL ANALYSIS.

A chemical analysis determines the present and past pollution of a water, and generally distinguishes between vegetable and animal matter, and, when the results are properly interpreted in the light of the sanitary survey, they often show whether a water is unsafe for drinking. Sanitary water analyses are usually reported in parts per million, so far as chemical results are concerned, because a litre of pure water at its maximum density contains exactly 1,000,000 milligrammes.

The total solids should not exceed 1000 parts per 1,000,000 parts of the water, because the use of such water overworks the kidneys in removing the waste products from the body. The best drinking waters contain usually not more than 500 or 600 parts of solid matter, which amount is nearly constant at all seasons of the year and in all parts of a distributing waterworks system; and it is not until this amount is exceeded that the water usually reveals the excess through the taste of its salts. Any decided variation from constancy in the amount of solids generally represents contamination and faulty management, and this is so marked in the water from "dead ends" that we sometimes find from thirty to forty times as much solid matter here as exists in the normal supply of the plant.

Loss on ignition, as determined by the refined methods adopted by some chemists, is not of especial interest to the sanitarian, since the principal value to be ascribed to this determination is from the qualitative indications of colour and odour evolved. A blackening of the residue indicates organic matter, which disappears somewhat in proportion to its instability, and, when it evolves little or no odour, the organic matter is probably of vegetable origin. But, when the odour is strong and disagreeable, the contamination is generally from animal sources, or is highly concentrated, and the water requires no further investigation to show that it is polluted and unfit for domestic use.

The chlorine in ground waters or in uncontaminated streams is generally small, and is constant at the same season in all parts of a distributing waterworks system; its amount should be nearly the same as that of the normal chlorine in other pure waters near by. Immediately after heavy rains, the amount is greatly reduced by dilution, and during a drought it is excessive, but is the same at all points in one locality. Any variation from constancy in the amount of this element should be studied with care, and its cause ascertained. Chlorine is in this way an important means of detecting sewage contamination, but it is of no aid whatever in detecting vegetable refuse.

In an investigation of a public water supply all tributary streams and rivulets should be examined; whenever marked variations in the chlorine occur, they are generally due to animal contamination, or to saline deposits near by. But the absence of this element, its small amount, or its constancy in a water, is absolutely no evidence that the water is pure and wholesome, because vegetable matter, which is practically free from it, may be there in any proportion, and thus render the water unfit for domestic use.

Free ammonia in water represents albuminous matter in a decomposing condition, and, when this is of vegetable origin, it is often noticeable, in Nesslerising for the free and albuminoid ammonia, that the colour is decidedly yellowish-green, instead of chocolate, and is especially distinct after the second or third fifty-cubic centimetre distillate. When the water contains urea, derived from urine, the organic matter is slowly decomposed, and the rate of distillation of the free and albuminoid ammonia becomes nearly constant after the first fifty cubic centimetres of each have been evolved; and a few of the last fractional distillates of albuminoid ammonia show nearly twice as much as the corresponding ones of the free. These facts are often of great service in detecting fresh sewage pollution. Surface waters suitable for drinking contain usually not more than ·050 part of free ammonia to 1,000,000 parts of water, and often much less when the albuminoid exceeds this limit.

Albuminoid ammonia is developed from undecomposed nitrogenous substances when under the influence of a boiling solution of alkaline permanganate, and therefore represents pollution in a fresh and possibly dangerous condition. When a large proportion of this is evolved in the first part of the distillation, the organic matter is very unstable and in a putrefactive state, and, whenever the total free ammonia exceeds the albuminoid, the water, if it be a surface one, is generally stagnant and insufficiently aërated, and a suspicion is always entertained of sewage contamination in an advanced decaying condition. Waters that contain

* *Engineering Magazine.*

less than ·050 part of albuminoid ammonia per 1,000,000 parts of water are organically nearly pure, and may generally be considered permissible, unless their origin is sufficient to condemn them; those that contain from ·050 to ·100 part are really dirty; while those that contain more than ·150 part of albuminoid ammonia should be condemned as unsafe for human consumption. In an investigation of a recent typhoid-fever epidemic at Duluth, Minnesota, where 2000 persons fell victims to the disease, the city water, which was its cause, contained only ·090 part of albuminoid ammonia per 1,000,000 parts of water. This one case shows how small an amount of albuminoid ammonia may be indicative of sewage pollution.

The oxygen consumed is generally in proportion to the carbon and hydrogen present in the organic matter of the water, and it often enables us to distinguish between vegetable and animal contamination. Permissible waters usually require not more than 1½ to 2 parts of oxygen per 1,000,000 to destroy their organic matter, and, when the amount exceeds 3½ or 4 parts, the water should be considered with suspicion. Whenever the amount of oxygen consumed is comparatively large and the albuminoid ammonia small, the contamination is usually of vegetable origin, and, when the oxygen is small and albuminoid ammonia large, the organic impurities are either of animal origin or concentrated albuminoids derived from vegetation.

Nitrites are compounds formed by the oxidation of ammonia in presence of weak bases, or are produced from nitrates through organic decay and bacterial action. They are very unstable salts, and frequently exist in cemetery drainage and badly-polluted surface waters. Any water having nitrites in measurable quantity should be regarded with suspicion, and many surface waters should be condemned by their presence alone.

Nitrates are the final products of oxidation of the nitrogen of organic matter, and therefore represent past pollution. Their normal amount in permissible water is generally very small, oftentimes not exceeding a mere trace, and their presence in a stream, or in the distributing system of a water works, in amounts above that of the original water supplying it, or the ground water near by, is evidence of contamination. This pollution is often due to faulty management in allowing suspended matter to accumulate in the mains; all "dead ends" should be flushed at frequent intervals.

THE MICROSCOPICAL EXAMINATION.

Under the microscope the suspended matter which separates from a water upon standing, like silt and other substances which might irritate the intestinal tract, can be studied with precision, and the results are often of great value in determining its sanitary quality. The writer has detected, in wells and streams used for domestic supply, particles of hair, excreta, oil globules, epithelia, and other filth derived from surface drainage or sewage, such as decaying vegetation, and it requires no argument to show that all such water is loathsome and unfit for domestic purposes. The microscope also enables us to study algæ and the animal micro-organisms of water, such as paramecia and other sewage ciliata which have been traced directly from the source of contamination to the point of supply; and we thus judge of the character of the water by knowing the habitat of these micro-organisms. The various entomostraca, such as cyclops and daphnia, can also be best studied with the microscope, although they can be easily seen with the naked eye. These organisms were once held as indicative of purity, but they are also found in water contaminated with drainage, and we now know that their presence has no significance.

THE BACTERIOLOGICAL EXAMINATION.

Bacteriology offers considerable service in the study of a water supply, by determining the number of micro-organisms in a given volume of it. This science is particularly valuable in ascertaining the efficiency of filtration, and it also sheds some light on nearly all natural waters. Those from exceptionally pure sources, such as springs, deep wells, and rain or snow that falls at the end of storms, have but few bacteria in them, and the best ground and surface waters usually contain no more than 200 or 300 per cubic centimetre. The number of micro-organisms generally increases with pollution, until sewage is reached, with its millions per unit volume; and, when there is a large number of sewage bacteria, it is probable that pathogenic germs are among the lot.

Since bacteria are absorbed from the air, the best surface waters must contain them, and no fixed standard of permissible limit is given. The number of micro-organisms depends entirely upon local conditions, always being more in thickly-populated districts than in mountainous and uninhabited regions. But some eminent authorities hold that a drinking water should not contain more than 1000 germs per cubic centimetre, and the Sanitary Authorities of some large cities, having municipal waterworks, advise the inhabitants to boil the water whenever the number of bacteria in it exceeds this limit. Systematic tests are frequently made to ascertain efficiency of filtration by determining the number of micro-organisms in the unfiltered and effluent waters; and mechanical filters are now operated so perfectly by the use of alum cake as a coagulant, that from 97 to 98 per cent. of the bacteria are removed. Some filter companies now guarantee to remove 96 per cent. of the micro-organisms, and reduce the albuminoid ammonia at least to ·150 part per 1,000,000 parts of the water, and any system of purification that falls short of these results is unsatisfactory in proportion to the degree of failure.

Some investigators attempt to determine the wholesomeness of water by searching for its pathogenic germs, while others inoculate guinea pigs and rabbits with a culture medium which has been impregnated with the water and kept at the temperature of the human body for some time, and then study the effect with a hope that, if the water is disease-producing, physiological symptoms will develope characteristic of disease. But the numerous and tedious operations required for the identification of any species of bacteria, and the improbability of finding it, render the search almost hopeless at the beginning and usually fruitless in the end. This is not strange when it is remembered that only a few drops of water are operated on at a time. No polluted water, or even sewage, is teeming with disease-producing germs, and they can be expected only in very inconsiderable numbers compared with those of other bacteria present.

There are but few cases on record where the Eberth bacillus has been satisfactorily isolated from

water supplies, and it is doubtful whether there has been a case on the American continent. The resemblance of this bacillus to certain water bacteria has often confused inexperienced investigators, and some bacteriologists distrust even their own results, and change their views after the "test of experience" has been made. But we can detect with certainty the *Bacillus coli-communis*, which is a normal inhabitant of the intestines of man and some other animals, and its presence is sufficient to absolutely condemn a water which contains it, in the absence of a system of thorough purification.

DETECTING ORIGIN OF POLLUTION.

It is sometimes desirable to determine the origin of pollution of a water supply. This is done by introducing into the various suspected sources some foreign substance that can be readily detected in the water, and yet will be harmless if taken into the system in small quantity with the water. By comparing the chlorine of city wells before, with the excess found some days after, a large amount of common salt and water has been added to adjacent privy vaults, serious contamination is often detected. The celebrated case of contamination of the Lausen (Switzerland) water supply was detected by placing a large amount of common salt in the suspected polluting stream, about a mile distant, on the opposite side of the Stockhalden, after which it appeared in the spring at the base of the mountain that furnished some of the inhabitants of the town with water. Lithium chloride, which is detected spectroscopically in minute traces, is sometimes used for the same purpose, and has given great satisfaction in legal investigations. The use of fluorescene, which gives a magnificent yellowish-green fluorescence to water, even in the smallest quantity, demonstrated an underground connection between the rivers Danube and Ach; and in the investigation at Duluth, above referred to, sodium fluorescene placed in a sewer appeared at the end of the intake, at a distance of several hundred feet from the shores of Lake Superior, in four and a-half hours, and remained for forty-two hours, thus showing, in the most satisfactory manner, the sewage contamination of the city water supply. Aniline red, aniline blue, and in some cases even Prussian blue have given satisfactory results in detecting the origin of pollution. Whenever any of these substances demonstrates a connection between a water supply and sewers, privy vaults, or other sources of contamination, the water cannot be used with safety for drinking, except after boiling or sanitary filtration.

CHELSEA.—At a recent meeting of the Vestry the Medical Officer of Health, reporting upon the smoke nuisance in the parish, recommended that notices be prepared, stating that in the opinion of the Vestry it is necessary that all furnaces used for generating steam which are, or may be, within the parish boundaries, should be so constructed as to consume the smoke arising from any combustible that may be used therein, and that such notices be forwarded to the various persons concerned, together with an intimation that in future a strike in the Welsh coal trade, and a deficient supply of smokeless coal, will not be accepted as an excuse for the infringement of the smoke provisions of the Public Health Act. It was resolved that the report of Dr. Parkes be approved.

SANITATION OF COUNTRY HOUSES, VILLAGES, AND SMALL AREAS.*

By EDWARD TIDMAN, C.E., F.S.I.

(*Continued from page* 618.)

ANOTHER process of treatment is the "Alumino-ferric," which is applied in the form of solid slabs or in solution; by the latter process an automatic appliance is provided for dissolving the slabs as required. After treatment, the precipitate formed is allowed to settle in tanks varied in capacity to suit the volume of sewage to be treated. The automatic supply can be fitted to existing tanks, and the working expenses are nominal, the cost of the charges being about £3 per ton, and the quantity required averaging 12 tons per 1000 population per annum, so that the cost per head in a mansion would be small if properly managed.

The treatment of sewage by works provided for bacteria cultivation has now for some time caused considerable attention to be paid to the bacteria treatment, and although this treatment is by no means yet the "active agent" in the purification, was not properly credited with the good work done by it in removing solids from sewage. The author, some thirty years ago, constructed a sewage outfall treatment for a small town in the North of England, where gas coke was used for the filtration, and with excellent results—so much so that at no time since has any complaint been made of the outfall effluent, although it runs direct from the tanks into a tidal brook, and eventually into a tidal river, close to a town of some 60,000 inhabitants, but he was not then aware that the bacteria were his friend in assisting to secure this good result.

It is of course well known now that the purification that takes place in sewage by passing it through land or artificial filters is mainly due to the transformation of the complex organic matters in the sewage into more simple and harmless forms, not liable to putrefaction, and therefore causing no nuisance.

Until very recent years it was always usual to lay down in any scheme of sewage treatment settling or subsiding tanks, into which the sediment would be deposited, and afterwards removed in a foul and offensive condition and at great cost, and before the liquid was run on to land. But it has now been found that crude sewage can be satisfactorily purified by the bacterial organisms without any previous treatment whatever, either chemically or by subsidence, thus obviating much of the expense and nuisance always attached to such treatment.

The bacteria which affect this change are present in crude sewage in enormous numbers, and by proper care their work and numbers can be increased to an unlimited extent; but proper treatment is necessary for such delicate organisms as bacteria are, and their natural and suitable surroundings provided for, or they will be killed and their utility crippled in a more or less degree, and the result prove unsatisfactory.

The failures in many expensive sewage outfall schemes are no doubt due to the want of consideration of these requirements, or the want of knowledge

* Paper read at the Northamptonshire and Adjoining Counties Branch of the Sanitary Inspectors' Association, at Northampton Town Hall, May 21st, 1898.

by those in charge, and no system of sewage disposal will be efficient or remain efficient without proper care and attention, and the provision of a competent and capable official to attend to the working and management of sewage schemes is a *sine quâ non*, if satisfactory results are to be obtained; and no doubt the best results are secured if Local Authorities keep the management of their sewage disposal in their own hands and control, as the self-interest of tenants frequently ends in failure as regards sewage purification.

It is only within the last few years that it has been ascertained that two different classes of bacteria can be utilised for sewage purification; one class consisting of bacteria that require the presence of air, or, at any rate, "oxygen," for completing or carrying on of their processes. These are known as "aërobic" bacteria, whilst the other class consists of bacteria which flourish best in media from which air and light are as far as possible excluded, and are known as "anaërobic" organisms.

The value of the latter class in sewage purification has only recently been recognised; they act on both nitrogenous and carbonaceous organic matters in suspension, part of which is resolved into similar constituents, whilst the larger proportion is liquefied or rendered soluble, and therefore more easily acted upon by aërobic bacteria. It is these anaërobic bacteria which are made use of in the patent septic tank, which for some time has been working at Exeter, and which will be described later on.

Sutton, in Surrey (population about 16,000), has been using bacteria filters with excellent results. Mr. Dibdin, the late chemist to the London County Council, having experimented elsewhere, induced the Urban District Council to give the bacteria cultivation filter a trial. Two of these filters, capable of dealing with about 30,000 gallons of sewage per day, were constructed late in 1896; the filtering materials being burnt ballast (or clay burnt on the ground, at a cost of about 2s. 3d. per cubic yard), and the crude sewage being run on to the first filter without any treatment beyond passing through two roughing screens.

The following is a description of the first or rough bacteria filter:—It has a superficial area of about 183 yards, and a depth of about 5ft., and its capacity is about 218 cubic yards, and it holds, when full, 36,000 gallons; and when filled with burnt ballast, 13,500 gallons, or rather more than one-third sewage to two-thirds ballast. The sewage is applied at about the rate of 180 gallons of superficial yard of filter, which is equal to nearly 900,000 per acre of filter area per day. At the bottom of the filter is a 6in. drain, from which 3in. drains radiate to the walls at intervals. The ballast which is used as the filtering material is, after burning, screened through a half mesh, and all that passes through is discarded, the remainder only being used in the filter, the larger pieces at the bottom and the smaller in the middle, and the top is composed of yet coarser pieces. The raw sewage passes directly on to the top of the first filter, which it takes about three-quarters of an hour to fill, care being taken that the sewage, when the tank is filled, does not rise above the top of the filtering material. The sewage is allowed to stand in the filter in contact with the ballast, and subject to the action of the bacteria for at least two hours, after which the valve at the bottom of the filter is slowly opened and the effluent run on to the second filter, which is placed at a lower level.

The second filter is constructed much on the same lines as the above, only that the filtering medium is much finer. The effluent in the first tank is allowed to stand in the second tank after the filling is complete for two hours, after which time the tank is slowly emptied by means of a valve at the bottom.

The effluent from the first tank, though not free from smell, is fairly clear, and almost free from suspended matters of the crude sewage, and also a considerable portion of the dissolved organic matter having been removed, while the effluent from the second tank is invariably, it is stated, clear, colourless, free from smell, and not liable to subsequent putrefaction, and fit to be discharged into any watercourse.

The construction and the management of the filters have been under careful supervision. The effluent has been periodically analysed and examined, and the results, as published, are most satisfactory.

The time taken from the commencement of the filling of the first filter is about six hours, and by the holding up of the sewage in the tanks, and subsequently drawing it off from below, aëration of the filters must occur, as air must be drawn in from above to take the place of the liquid that is withdrawn. The filters should rest for two hours after they have been emptied, so as to permit of thorough aëration and revitalisation, and they are also allowed complete rest for twelve out of every twenty-four hours.

The action of the filters is essentially a biological one, and the full bacterial action is not fully established, until the filters have been in action for several weeks, as the bacteria have to establish themselves and multiply in the filtering medium, and it is especially during this period that care is necessary in the management of the filters.

The author has constructed several filters on this principle for country houses, and the cost is very small. In one case, where there is a school with a population of about eighty inmates, the cost of the tanks was about £50 only, and the attention is limited to an assistant gardener altering the valves once in twenty-four hours and cleansing the roughing screens, taking about one hour only daily, therefore the working expenses are very small.

The filtering material need not be burnt ballast. Clinker, scoriæ, or slag will be equally efficient for the first filters, and gas coke or fine gravel can be used in the second filters. There are no patent rights attached to this system of sewage disposal, and in the matter of cost it must contrast favourably with any other system, where patent rights or royalties are involved.

The Ducat filter, as erected at Hendon, is a bacterial filter, but the construction differs from that described above, inasmuch that the walls are constructed of agricultural field pipes, with an inclination downwards and inwards, with the object of allowing free access of air to all parts of the tank, and to ensure the passage of air into the interior of the filter. A layer of aërating pipes are also laid horizontally through the filtering material at intervals of 18in.

THE SEPTIC TANK SYSTEM.

The chief feature of this system is the passing of the crude sewage through one or more long tanks, from which air and light are, as far as pos-

sible, excluded, prior to treating it on bacterial filters, as previously described, the sewage remaining in the septic tank about twenty-four hours; it enters and leaves the tank below the water-line, so as to cause as little disturbance as possible, and has grit chambers, which remove part of the mineral matter. Within the septic tank a scum is speedily formed, and the action of the tank appears largely to depend upon the presence of this scum; the changes in the sewage within the septic tank are the result of fermentative action, brought about mostly by anaërobic or liquefying bacteria, and consist in the removal of about 55 per cent. of the suspended matter, and 30 per cent. of the oxidisable organic matter; while the free and albuminoid ammonia are also reduced, and the condition of the remaining organic matter is changed, so that it is more easily broken up by subsequent bacterial action in the filters. Marsh and other gases are given off, and there is little odour present; about one-eighth of the usual deposit is left in the septic tank. The effluent is somewhat turbid and discoloured, and it is further necessary to aërate the effluent by passing it over the edges of an aërator in thin sheets, in order that it may take up oxygen, and is then conducted on to the filter beds, composed of crushed clinker and coke breeze, and eventually a high degree of purity is attained.

GARFIELD COAL FILTERS.

The Garfield coal filters are at work at Wolverhampton, Lichfield, and Tipton, and are spoken highly of by Dr. Reid, M.O.H., Stafford County Council, but the author has had no experience of their action. This filter is composed of coal of various degrees of fineness, and is allowed to rest for twelve out of every twenty-four hours; the top layer of coal being well washed before use.

Until the last few months the author has generally treated mansions and small installations of sewage treatment through settling tanks, and after thoroughly removing the solids run the liquid through subsoil drains under meadows or kitchen gardens, where the fall would permit, and by this means a practically pure effluent is obtained, and the growing crops over are much improved; but keeping the settling tanks cleaned out seems always a difficulty in country houses, but since the introduction of the bacteria tanks—and their success has been proved — he finds that their automatic action in removing the solids from the crude sewage, and by the subsequent treatment of the effluent by subsoil irrigation, there is no system that answers so well and efficiently, as regards initial cost, working expenses, and purity of the effluent, as the bacteria tank system.

For much of the information contained herein with regard to sewage treatment, the author is indebted to the inventors of the various systems, to the Surveyors in the districts where the works are situate, and last, but not least, to Dr. T. Eustace Hill and James Robinson's report on "Sewage Disposal to the County Council of Durham," and many thanks are due to them for their courtesy and assistance.

Having now dealt somewhat fully with the outfall into cesspools, and treatment on land, and by precipitation in tanks, &c., a few words about the discharge of sewage into the sea, which is the ultimate end of all sewage purified or not. In draining into the sea, care should be taken to fix the outfall sufficiently into deep water to render pollution of the banks impossible; to prevent the tidal water getting back into the drains; to provide sufficient capacity for the water impounded during flowing tide, and for the special ventilation of the drains when tide locked.

The subject treated upon in this paper would not be complete without some reference to the midden, privy, pail, and other dry or semi-dry system in use. There can be no doubt the old midden and privy system spread filth. Diseases, cholera, and enteric fever, and diarrhœal complaints are increased by it. The wells are polluted, the air fouled, and in many other ways it is objectionable. These may be lessened by their being made water-tight, frequently cleansed, and with movable receptacles; one of the best being that known as the "pail system," where the excreta is caught in pails or tubs containing absorbent deodorising material, and frequently emptied and treated with sulphuric acid, say, 30 lb. to the ton.

"Moule's" dry closet system may be adopted in some cases with advantage in out-buildings of mansions, in villages, and public buildings. The objection to this system is the trouble of providing dry earth, the expense of cartage, the offence to the sight, difficulty of securing proper attention to the working, small value of residual manure, and its excreta being frequently placed too near the houses.

It is, however, cheaper than water-closets, requires less repair, is not injured by frost, reduces the quantity of water required per head (an important advantage in some districts).

And now, in conclusion, the author must express his regret at the dryness of the subject, and probably handled with little novelty to many of you, who have frequent opportunities of hearing the subject treated by the various learned societies more closely allied to the engineering department of the profession than ours; yet it must be remembered that the Association has many members scattered over the Empire and Colonies who may find useful help from its perusal, and to such as only read our *Journal*, there may be more novelty and information than to those here to-day, who have given such patient attention, and it is hoped that the discussion to follow will add information useful alike to his audience and the author.

An interesting discussion ensued, and a vote of thanks was passed to Mr. Tidman.

ESHER AND THE DITTONS.—It has been decided that a committee be formed whose duty it shall be to report on the administration of all working-class dwellings in the possession of the Council, and to submit plans and estimates to the Council should it be desired to acquire additional working-class dwellings, such plans and estimates not to involve any charge upon the rates. At the meeting of the Council, where this decision was made, there was considerable discussion as to the scope of the reference, but Mr. Greening put the matter right by explaining that he wanted a committee solely for the purpose of gathering information about the cost, erection, and plans, &c., of working-class houses, should the Council at any time decide to erect or take over any such houses.

MUNICIPAL ENGINEERS AT NORWICH AND YARMOUTH.

In continuation of our report on page 647 in our last week's issue, we have to note that on Saturday morning, the 18th inst., the members left Norwich at 9 a.m. by boat, generously provided by Messrs. Collins and Cockrill, and proceeded down the rivers Wensuon and Yare to Brundoll, whence they took train for Yarmouth. A meeting was held in the Town Hall, Yarmouth, at 12.30 (noon), the members being welcomed by Mr. Burton, chairman of the Sanitary Committee of the Corporation (in the unavoidable absence of the Mayor), luncheon being also kindly provided by the Mayor for the members. The chair was occupied by Mr. J. T. Eayrs (past president). The following paper on "Some of the Recent Works Carried Out by the Great Yarmouth Town Council," was read by Mr. J. W. Cockrill, Borough Surveyor.

It is now twelve years since the author had the pleasure of welcoming the members of the Association to this town. The meeting then held is reported in our "Proceedings," vol. xii., pages 119 to 154.

Sewers.—The work of re-laying the whole system referred to in the former paper has stood well, and the purpose for which it was undertaken has been fully realised, for out of nearly one hundred miles of sewer under the author's charge, there is not one mile but which is absolutely self-cleansing, and in a town so flat as Yarmouth this may be considered satisfactory. The works of flushing, to be spoken of hereafter, have much to do with this. Since 1886 many extensions have been made to the sewerage works. New pumping stations on the main sewer outfalls, to prevent the tide-locking of the sewers, have been erected, and flood-prevention works have been carried out, the cost of which in the aggregate has been about £25,000. These works comprise about one mile of 5ft. egg-shaped and 1¼ mile of 3ft. egg-shaped sewer, built in concrete with a salt-glazed tile facing—the cost was remarkably low; a sample piece has been set up for your inspection at the depôt. The 5ft. sewer cost 33s. per yard run, and the 3ft. sewer 20s. per yard run without digging. The glazed surface keeps itself clean, and can very easily be swept down. The low cost is due to the very great facilities we have for making concrete, the clean shingle being delivered on the works, ready for use, at 1s. 3d. per yard cube. These sewers were put in to prevent the flooding of some of the low-lying districts, which were found to be flooded in very heavy rains and thunderstorms. The pumping stations which have been erected are placed across the two largest sewers we have near the outfalls, and the man in charge pumps whenever the accumulation of sewage reaches the height which would mean tide-locking the connections into the main sewer. The pumps at the larger station to be inspected are Gwynne's centrifugal 15in. and 24in., driven by Otto gas engines of 14 and 20-horse power. They are capable, with their lift averaging 6ft., of raising quite a million gallons per hour. At the second station two 12in. centrifugal pumps are put in; the benefit derived from these installations is very great, as not only is the tide-locking of the sewers prevented throughout the year, but in the winter time, when a strong north-west wind is blowing, the tide holds up the river three and four days at a time to such a height that no sewage can pass out by gravitation.

Sea-water works.—These were completed on the lines which were described in the former paper; but the success of the undertaking on all points was so marked that the Committee determined very soon to extend the works, and instead of the £4500 which the original works cost, more than £10,000 has now been spent. The saving to the Corporation is very great, as the following figures will show. The cost, including repayments of capital, interest, and all working expenses, has been about £600 per annum during the last few years since the extensions, and for this quite 100 million gallons of water have been raised to a height of 45ft. and distributed over the town, or at a cost of less than 1½d. per 1000 gallons. The street watering takes about seven million gallons, and sewer flushing the remainder. The water is supplied free to most of the Elementary and Board Schools in the town for flushing closets, urinals, drains, &c., some fourteen houses also have it laid on for baths and drain flushing.

Flushing is carried out by some twenty-five automatic flushing tanks, varying in capacity from 3000 to 1000 gallons, and with outfalls of from 9in. to 15in. diameter, besides about 250 flushing valves, varying from 6in. to 3in. diameter, according to the size of the sewer to be flushed; but I have found that 3in. and 4in. pipes with delivery direct into the sewers will provide sufficient flush for 9in. pipes, and that sewers up to 15in. diameter can be kept clean with the larger sized valves. The saving in the roadwork is very considerable; the sea water has a most beneficial effect on light roads made with gravel or flint. No damage is done on the heavier granite macadam, but a greater amount of cleaning is required in the autumn. The saving on the light roads by the use of sea water, in my opinion, is quite £500 per annum, spread over about twenty-five miles. In addition to the saving caused by the water costing only 1½d. per 1000 gallons instead of 1s., there is from two to three million gallons less used than there would be if fresh water were employed. The saving in horse hire in distributing is quite £250 per annum, and the work is much more effectually done. A less number of complaints are received at the author's office now in a whole season than in a week during the time fresh water was used.

Previous to its introduction the chemists employed by the Water Company prophesied all sorts of evils as the result of using it for sewer flushing, which have not come to pass. Its use has been most effectual in preventing nuisances from sewer gas, as not only is there the mechanical action of the flush, which scours the sewers out, but there is the change of air in the sewers caused by the large rush of water, and as there are few sewers in the town but are flushed every other day, this is a very important factor in ventilating and changing the air in them. In the sewerage of the Old Rows, of which there are 145, averaging about 150 yards in length and less than two yards wide, which have been recently sewered, each sewer has its own flushing valve at its head, and is by this means kept perfectly clean. The length of water mains laid in the streets is now 13 miles, of sizes varying from 8in. to 3in. diameter. All members of this Association will appreciate the advantage of having com-

plete works of water supply for sewer flushing under their own control, and the convenience of being able to flush without fear of interfering with the domestic supply of the town. The author has in his case the sea to draw from, which is salt, and there are many advantages in using salt water; but there are few towns in which a supply of water exists of not sufficient purity for drinking purposes, yet clean enough for street watering or sewer flushing, which could be made available.

The concrete footways have been considerably extended since the last visit of the Association. During the sixteen years which the author has been responsible for the work of this town he has laid some forty to fifty miles. The facilities for obtaining materials are very great, and shingle ready for the work, entirely free of sand, is delivered in the streets at 1s. 3d. and 1s. 6d. per yard cube. This permits the path, 3in. thick, to be laid at a cost of 2s. to 2s. 2d. per yard superficial by the Corporation staff. Contracts, however, have been let and completed at from 1s. 8d. to 1s. 9d. per yard superficial.

Destructor.—The growing difficulty of disposing of town rubbish has for some years been apparent in this town, and although recreation and pleasure grounds have been formed with this material during the last ten years—the author has laid down 32 acres of this class of ground on sandy waste land, similar to and partly on our beach—the cost and upkeep of these grounds prevent too great an extension, and the Town Council have reached a point beyond which they cannot go at present. It thus became necessary to decide on some other course. Great difficulty has been experienced for years in getting the farmers of the neighbourhood to take it, and when they did the sorting and selection created great nuisances; and, as these farmers would only cart it away at times convenient to themselves, it caused an accumulation on the quay, used for deposit about a mile out of the town, of a heap frequently of 5000 to 10,000 tons. The author was instructed to consider the question of the desirability of conveying and tipping out at sea or of burning. On the first point he found that the cost of plant, with its attendant items of interest and sinking fund, the cost of upkeep and towage, with the certainty that in the most favourable winter there would be times when for three or four days it would be impossible to take the hopper barges over the bar, made it as costly as any mode of burning, and the uncertainty was a great drawback, as it involved keeping plant which would depreciate quickly, and for which the quay space was very limited.

The next point raising any controversy was the site. At the present depôt the Town Council had a splendid site with good foundations, a railway close by, the engineer for which was prepared to take the whole of the clinker and pay for it, but as the site adjoined the isolation hospital, and was within 100 yards of the workhouse, the Local Government Board refused its consent. The remainder of the land in the neighbourhood being Corporation estate, which is fast being developed for better-class dwellings, it was felt desirable not to do anything which, if only in a sentimental sense, might depreciate this estate. It was determined to erect the destructor on its present site, the foundations of which are very bad; the river Bure adjoins it on the west, and the mean level of the water in the same is above the level of the marsh; the soil is for the first foot or two vegetable mould, then there is about 2ft. of sand which is full of water, and then for nearly 20ft. a soft alluvial deposit, locally known as ooze. The utmost bearing capabilities of the soil about 6in. from the top after removing the sod, was by experiment found to be 10 cwt. per foot superficial; the bearing capabilities of the ooze not being more than half this. At the depth of 22ft. is found a bed of good sand and gravel, and borings on the site show this to be at least 15ft. thick. The author's previous experience in this soil has shown that a large quantity of water is to be met with at a point about 5ft. above the sand level, and the knowledge of this has led to the method of carrying out the foundation work hereinafter described. The very poor quality of the refuse of the town, which contains a large percentage of sand with the contents of some 3000 privies, will give poor calorific results; and the present installation only provides for fixing an 80-horse power boiler, the steam from which will be used for fans, for forced draught, a dynamo from which light will be obtained for the works, and motors for sewerage lifting at a station near by. The number of cells to be fixed at first is ten of Manlove, Alliott, and Co.'s latest type, but the building provides for four additional cells, making fourteen in all; or two cells can be put in with Babcock and Wilcox boilers between them and the end of the present ten cells, so that each boiler could be heated by two cells should any work be found for the steam. The cells are to be fitted with Boulnois' patent charging apparatus, and the furnaces with Messrs. Manlove's clinker furnace.

The chimney is to be 200ft. high, starts square at the base, is octagonal for 50ft., and then goes up circular; inside it is a parallel tube 6ft. in diameter with fire-brick lining the whole height, and kept at least 4in. from the outside shaft; for half its height it is 13½in. thick, and for the remainder 9in. thick. The chimney stands in a very exposed position, and the top is kept plain with very little overhang. The exposed position of this building, and the rather unusual practice of having a tipping platform on both sides of the cells, which involved a very wide span for the roof, led the author to form a level roof in concrete; the cost working out less than it would have done if covered with a slate roof with the usual pitch, besides which the weight is more equally distributed, and the wind forces exerted upon it are very small. The tipping floor and roof of the engine-room, which forms the summit of the inclined approach, are formed with trough flooring, covered with granite setts, paved on concrete with asphalt joints and bed. The foundations, which are now in progress, for the chimney and main buildings are to be on cylinders. The chimney weighs 2300 tons, is to stand on sixteen cylinders, each 6ft. 6in. diameter, and gives a weight, including the cylinder, of 4 tons 6¾ cwt. per foot superficial on the bed of sand and gravel.

The main building is to stand on twenty-six cylinders of 5ft. 6in. diameter, and gives an average of about 3 tons 5 cwt. per foot superficial on the soil. The cylinders are constructed of concrete blocks 9in. thick, built in the ordinary way. At first it was intended to have built them in brick, but the author found that he could make the concrete blocks cheaper, and build the cylinders quicker

with them than with brick, which would have had to be specially made. The blocks are 9in. thick, 9in. high, 15in. long on the face; the lower 4ft. is encased in a wooden drum with a cutting edge, and sunk into the gravel and sand about 2ft.

Until the main spring of water is met with the cylinders will be sunk by men filling buckets in the ordinary way, but rather than pump large quantities of water—which would have the effect of disturbing the adjoining cylinder—the work of sinking will be carried on by a circular grab now being made by Messrs. Priestman, of Hull. For the work of levelling the soil at the bottom and placing the two courses of concrete blocks a diver will be employed. The joints of the concrete blocks are to be grouted up with liquid cement, which will be passed into the joints through a 3in. pipe; this will be allowed to stand three or four days to set, when the cylinders may be expected to be watertight; the water will then be pumped out and the cylinders filled with concrete. Such is the method in which the author is proposing to form the foundations, but as the work is being carried out without the aid of a contractor it is subject to such alterations as may be found expedient and likely to give a satisfactory result. It is hoped that before the members meet a cylinder or two may be sunk to the required depth; at the time of writing the only thing likely to hinder this is the delivery of the plant. The foundations of the engine-room, which is only one storey high, are spread, so that no portion has a greater weight than half a ton per foot superficial on the same.

Isolation Hospital.—The town is well provided in this respect. The cholera scare of some few years ago led to the provision of a rough temporary building near the harbour's mouth, and its being kept permanently ready for such an emergency. In addition, about 1½ mile into the country, a group of wooden and corrugated iron buildings have been erected for small-pox; these are somewhat extensive, and although they have now been erected some five years they have not been used. They consist of two pavilions capable of accommodating fourteen beds each, a receiving ward for three beds, with nurses' room and kitchen, an administrative block, and a laundry block. It stands on a good open high site in the country, and if it should be unfortunately needed will serve effectually to isolate, without any addition, at least thirty patients, while temporary provision could be made inside the ground for twice as many more.

The isolation hospital for fever cases is a permanent erection, the nucleus being erected four years ago, consisting of an administrative block, two small blocks, with male and female wards on each side of a nurses' duty-room. A large double-ward block similar in plan, and a block for laundry and disinfecting purposes, which also include ambulance store, mortuary, and receiving and discharging-rooms for patients, with store for their clothing. The extensions now being made consist of eight bedrooms to the administrative block, a large double-ward block of the usual plan, and, what is perhaps a rather unusual feature, a convalescent block for scarlet-fever patients; this consists of a day-room, two dormitories, two nurses' rooms, bath-room, and usual offices.

The author described the work executed and in progress for the recreation grounds and beach gardens, the old jetty, rifle butts, and accommodation for Volunteer encampments, and fish wharf quay wall.

Electric lighting.—As early as 1886 the author had been instructed to, and he had reported upon, the desirability of introducing the electric light into the borough, and in 1890 the Town Council obtained a Provisional Order, which they commenced to carry out in 1894; Mr. W. H. Preece, C.B., F.R.S., being appointed consulting engineer. The cost of the first portion of the installation was £15,000, but the demand for the light has been so great that at the present time the capital expended amounts to £33,000, and leave for fresh loans is asked from the Local Government Board, which will make the capital expenditure £40,000. The increase of the demand is shown in the fact that the lamps installed on April 1st, 1895, were 1600; in 1896, 5900; in 1897, 8600; and in 1898, 11,000. Up to the present the works have not paid full charges of interest and sinking fund, there being about £700 deficiency during each of the first two years, and £400 deficiency last year. The rate of progress in connecting additional lights shows that a profit may soon be expected. Last year the earnings on the capital expended was 4⅞ per cent., and if the Local Government Board would allow longer periods for the repayment of the loans these works would have paid their way from the first.

After the reading of the paper, a discussion followed, and votes of thanks were accorded to Mr. Cockrill, and also to the Mayor and Corporation for their hospitality.

Subsequently the members were driven round the district to view the numerous interesting works in progress by the Corporation.

NATIONAL REGISTRATION OF PLUMBERS.

PROVOST GLOVER presided at the annual public meeting of the District Council for Dumfries, Kirkcudbright, and Wigtown, in connection with the National Registration of Plumbers, at the Town Hall, Dumfries, on Saturday last.

In moving the adoption of the report, he said that the public themselves were perfectly satisfied as to the dangers of bad plumbing, and had been so thoroughly aroused that they had sought to arouse the plumbers, and it was to be hoped, after the attention the matter had received, on public and sanitary grounds, that the plumbers themselves would respond to the appeal that had been made to them to make sure that they entered into a proper appreciation of their duties as tradesmen, and that nothing but thoroughly good work was carried out.

The Town Clerk, Mr. John Grierson, moved a resolution that the Council petition Parliament in favour of the Plumbers' Registration Bill. He said that the Bill had been supported by large majorities in several divisions in the House of Commons. Even the opponents of the measure were practically one as to its aims and objects. The resolution was seconded by Bailie Hanlon, and carried.

It was announced that the next Congress of District Councils in Scotland would be held in Glasgow on the 18th, 19th, and 20th of August next, and in connection with it what is expected to be by far the largest and finest exhibition of plumbers' work that has yet been held.

Sanitary Inspectors' Associations.

NORTH-WESTERN AND MIDLAND.

THE inaugural meeting of the Midland District Centre was held on Saturday, June 11th, at the Council House, Birmingham. There were present representatives from West Bromwich, Bilston, Wednesbury, Stafford, Seisdon, Sedgeley, Uttoxeter, Birmingham, Coventry, &c. Mr. William Bland (Barton), who was in attendance on behalf of the Central Executive Council, took the chair at the commencement of the proceedings.

Resolutions passed at a meeting of Midland members, held at Stafford on March 26th, and at a special meeting of the Association, held on April 16th, having been read, it was unanimously resolved, on the motion of Mr. W. H. CONEY (Wednesbury), seconded by Mr. J. LOWRY (Seisdon), that the resolutions passed at the meetings referred to be endorsed, and that a Midland District Centre be formed.

The following officers were then appointed :—President of centre, Dr. George Reid, M.D., D.P.H., County Medical Officer Staffs. C.C.; district chairman, Mr. F. T. Poulson, Staffs. C.C.; Hon. Secretary, Mr. J. H. Carter, Sanitary Inspector, Council House, Birmingham. District Council: Messrs. Jas. Beech, Wolstanton; W. H. Clarke, Coventry; F. A. Faber, Birmingham; A. Hodges, Handsworth; E. W. Jones, Birmingham; A. Kent, Hanley; J. Lowry, Seisdon; E. G. Spears, Birmingham; R. Thornton, Fenton; H. Walker, Bilston; and T. Waters, West Bromwich. Scrutineers: Messrs. W. H. Coney, Wednesbury, and F. Thomson, Birmingham.

It was unanimously resolved that meetings be held on the last Saturday in each month.

The President (Dr. Geo. Reid) will deliver an inaugural address on Saturday next, June 25th, when the attendance of all Sanitary Inspectors in the Midland district is invited. This meeting will be held in the Council House, Birmingham, and will commence at 4 p.m.

The first annual meeting of the North Wales District Centre was held at Bethesda on Saturday last, the 18th inst. There was a large attendance of members present. The order from the Central Association constituting the District Centre having been read, the election of officers was then proceeded with, the following gentlemen being elected to the several offices mentioned :—President, Dr. P. Fraser, M.B., B.Sc., Medical Officer of Health Carnarvonshire Combined Sanitary Districts; Chairman, Mr. Ernest Worrall, Penmaenmawr; Vice-Chairman, Mr. W. H. Worrall, Bangor; Treasurer, Mr. Wm. Little, Llandudno; Hon. Secretary, Mr. R. John Hughes, Chief Sanitary Inspector, Rhyl; representatives on Central Executive Council, chairman and secretary *ex-officio*, and Mr. Evan Roberts, Carnarvon.

Mr. ERNEST WORRALL then delivered the chairman's annual address, selecting for his subject, "Our Programme." The address was of a most able and interesting description, and was warmly received. At the close of the discussion, Mr. Worrall replied to the vote of thanks and remarks of members.

The second annual conference of the Association is to be held at the Town Hall, Manchester, by kind permission of the Lord Mayor, on Friday and Saturday, July 1st and 2nd next. On the 1st proximo a series of meetings will be held, including annual meetings of the Association and North-Western District Centre, and of the newly-formed Central Executive Council, a special conference for members only being held at the close of these meetings.

On the second day the members will be formally welcomed to the city by the Lord Mayor and Chairman of the Health Committee (Alderman Walton Smith, J.P.). At the close of the reception the usual public conference, open to all Sanitary Inspectors, will take place, when discussions will be initiated on "The Local Government Act of 1894, and its Effect on Sanitation," "The National Registration of Plumbers," "The Training and Education of Sanitary Inspectors."

After luncheon a special excursion will take place, *viâ* the Ship Canal, to the Carrington Moss Estate belonging to the Manchester Corporation, where tea will be served.

A most successful meeting is anticipated.

Reports.

MEDICAL OFFICERS OF HEALTH.

Surrey County Council.

THE annual report of Dr. Seaton, the Medical Officer of Health for the County of Surrey, for the year 1897, contains a record of the progress made in the county in sanitary administration which is of considerable interest. The death-rate in the county for the year was 12·2 per 1000, and the birth-rate 24·7 per 1000. The zymotic mortality was 1·29 per 1000, being low, but the death-rate from typhoid continues, as Dr. Seaton remarks, to be unsatisfactory. Especial attention has been given during the year to the sources of water supply, and a conference of district Medical Officers of Health was held in March of the present year, from which much good is anticipated, as it resulted in a series of resolutions being arrived at which will tend to uniformity of practice and observations, which are so necessary in order to secure the desired end in view.

Dr. Seaton devotes one chapter of his report to a review of the Biological Methods of Sewage Disposal, which we hope to be able to publish shortly. Although the author appears to discuss the general principles of the biological process with considerable lucidity, we fear that his knowledge of the application in practice is, as we have had occasion to notice in the reports of other Medical Officers, not quite so satisfactory. No doubt the fact that the process is a new one is responsible for this. Thus, discussing (on page 54 in his report) the filter known as the coke-breeze filter, with which introduction the name of Mr. W. J. Dibdin is associated, and as adopted at Barking and Sutton, he states that the effluent from the septic tank process is directed on to "filter tanks of the type frequently referred to as in use at Wimbledon, Richmond, Merton, &c."

We had occasion to notice in our issue of May 13th last, on page 505, in our notice of the Wimbledon Sewage Works, the unscientific construction and working of the filters used there,

and we are therefore somewhat astonished to observe that Dr. Seaton falls into the obvious error of classing the coke breeze filters—used in conjunction with the septic tank process—in the category of some process at Wimbledon, where, in point of fact, no "filter tanks" exist, nor have we heard that any such exist at the other places named.

General News.

NEWCASTLE.—The Tyne Sanitary Authority propose an extension of the floating hospital.

CREDITON.—The Local Government Board has sanctioned the loan of £579 for purposes of water supply.

CARNFORTH.—The Urban District Council is considering plans for the building of slaughter-houses and other alterations.

WHITLAND.—The Rural District Council has resolved to carry out Messrs. Beesley and Son's scheme for the water supply of the town.

WESTMORELAND.—The total number of deaths registered in the county (exclusive of the parish of Kirkby Lonsdale) during the week ending Saturday, June 11th, 1898, was thirty, or equal to a death-rate of 24·3 per 1000 per annum of the estimated population. Two deaths were due to measles in Kendal.

BAMFORD.—On the application of the Rural District Council of Chapel-en-le-Frith, the Local Government Board has given its sanction to the borrowing by that Authority of £1750, with which to purchase land and construct waterworks at Bamford. The scheme prepared by Messrs. Sterling and Swann has been accepted.

RUSKINGTON.—The Local Government Board having compelled the Urban District Council to provide waterworks for the parish, plans by Mr. J. Clare, C.E., for a tower pumping station, &c., at a cost of £1709, have been forwarded to the Local Government Board for approval. The Urban District Council has resolved to borrow £1900 to cover the cost.

LONDON.—At a meeting of the Executive Committee of the Humanitarian League, held on June 2nd, the following resolution was unanimously adopted:—"In view of the failure of the present regulations to efficiently protect workers in dangerous trades, this Committee strongly urges the Home Secretary to prohibit entirely the industrial use of such deadly substances as white carbonate of lead and yellow phosphorus."

UDDINGSTON.—In view of the numerous complaints made by the inhabitants of Uddingston and the surrounding districts with reference to the depositing of ashpit refuse and other rubbish into an old disused quarry at Uddingston West Station, the Cleansing Committee of the district has entered into negotiations for the erection of a destructor in the vicinity of Fallside, about one mile north-east of Uddingston. The ground has already been measured off, and operations are expected to commence at once. The Bothwell Committee of the Cleansing Department has joined in the project, and it is quite possible that Bellshill will also join.

DUNOON.—At a recent meeting of the Cowal District Committee at Dunoon, it was agreed to form Kames into a special water district.

ESSEX.—During May there were only 72 cases of infectious disease notified in the rural districts, as against 95 for the corresponding period of last year. In the urban districts the figures were 260 and 258 respectively.

WIMBLEDON.—A proposal is under consideration for the purchase of a piece of land for a recreation ground. The Council has suggested a site, and resolved that £10,000 is to be the maximum expended on its purchase. Ten years ago less than half this sum would have purchased the same plot.

ROMFORD.—At the last meeting of the Rural District Council it was reported that the southern portion of the district was remarkably free from infectious disease, with the exception of measles, which had been very prevalent throughout the country. Three cases of diphtheria had been reported from Dagenham, but they were of an extremely mild character.

TIPTON.—The first prize of £25 in the public competition for the best plan for laying out the new Victoria Park at Tipton has been unanimously awarded to Messrs. William Barron and Son, Elvaston Nurseries, Borrowash. Their plan shows a lake nearly three acres in extent, cricket and recreation grounds, lawn tennis grounds, bowling-green, band stand, shelters, &c. They also furnish plans for lodge, entrance gates, ornamental fencing, &c. The park is thirty-three acres in extent. It will be laid out at a cost not exceeding £4500.

PADDINGTON.—We are informed that Mr. Frank Dethridge, Vestry Clerk of Paddington, has received from Dr. Tristram, Chancellor of the London Consistory Court, a faculty enabling the local Vestry to erect a town hall on the ground covered by, and at the rear of, the present Vestry Hall, Harrow-road, a building found wholly inadequate to present requirements. It is in contemplation to build a handsome town hall after the style of that at Portsmouth and Bolton, the site for which is, by the Chancellor's decision, already in the possession of the Vestry, without present pecuniary outlay.

LUMLEY BRIDGE.—The Earl of Scarborough having decided to erect a bridge across the river Wear, adjoining the existing ferry at Lumley Bridge, instructed Messrs. D. Balfour and Son, civil engineers, of London and Newcastle-on-Tyne, to prepare plans for a suitable structure, the contract for which has been let to Messrs. Head, Wrightson, and Co., of Stockton-on-Tees, who expect to start the work this month. The structure consists of a central span of 120ft. and two side spans, each 37ft. long. The main and approach girders are to be of mild steel lattice work, the bottom flanges being efficiently wind-braced and the top flanges supported with struts and overhead arches. The flooring to consist of creosoted timber with waterboards at each side. The piers to be each composed of four wrought iron piles properly braced, formed of four segments rivetted together, having cast iron pile points, and to be driven 21ft. below river bed. Gates and turnstiles are to be fixed at end of bridge and proper lighting arrangements to be provided. The structure is calculated to stand a safe distributed live load of 140 lb. to the square foot, with four times this amount for the ultimate load.

SURBITON.—At the meeting of the Urban District Council last week it was decided to increase the Surveyor's salary to £500 per year, with an advance of £10 per year for five years; that an Assistant Surveyor be appointed at £80 per year; that a competent foreman be engaged at a sum not exceeding £8 10s. per month; that the Sanitary Inspector's salary be increased to £150 per annum. In each case the officers are to devote their whole time to the work of the Council. The Clerk's salary was also increased.

DURHAM.—The scheme of water supply submitted by the Easington Rural District Council for Wingate Mill, Wingate-lane, and High Wheatley-hill, has been officially approved by the Local Government Board. It is proposed to obtain the water from the Kelloe Winning Pumping Station of Messrs. W. Scott and Co., Limited, where it is obtained from the sand feeder underlying the limestone, and will be pumped into a tank by a forcing set of pumps attached to the main pumping engine. The analysis certifies the water to be of excellent quality. After reaching the first tank, the water will again be pumped into an elevated storage tank to be erected on the highest point in the district at Wingate Mill, with capacity equal to several days' supply, from whence it will be distributed in cast iron mains over the district. The engineers are Messrs. D. Balfour and Son, of London and Newcastle.

NORWICH.—The annual meeting of the East Anglian Branch of the British Medical Association was held on the 16th inst. at the Norfolk and Norwich Hospital, the proceedings being conducted in private. After an inspection of the hospital, the meeting of the Council was held at eleven o'clock. This was followed by a demonstration of cases in the theatre. At noon the general meeting was held, when the usual reports were presented, and the retiring President (Mrs. Garrett Anderson, M.D.) introduced her successor, Mr. Haynes S. Robinson. Having been entertained at luncheon by Mr. Robinson, the members re-assembled in the Board-room, and passed the rest of the afternoon in the consideration of papers dealing with various medical and surgical subjects. In the evening the President and Mrs. Haynes Robinson received the members at afternoon tea in the keep of the Castle, and at seven o'clock the annual dinner took place at the Royal Hotel.

Personal.

MR. H. ROBINSON has been appointed Medical Officer of the Cottage Homes, Sculcoates.

MR. F. LEWIS has been appointed Medical Officer for the Fifth district of Steyning union.

MR. G. H. HUNTER has been appointed Medical Officer for the Haughley district of Stow Union.

DR. J. GORDON has been appointed Medical Officer for the Eythorne district of Eastey union.

MR. ROBERT HILL has been appointed Inspector of Nuisances for the urban district of Chesham.

DR. E. F. SYRETT has been appointed Medical Officer for the seventh district of Sudbury union.

MR. J. K. LEWIS has been appointed Medical Officer for the Rewe district of St. Thomas union.

MR. E. B. DENNY has been appointed Medical Officer for the Hainton district of Louth union.

MR. ARTHUR WILLIS has been appointed Medical Officer for the Sixth district of Newmarket union.

DR. JAMES GORDON has been appointed Medical Officer for the second Hougham district of Dover union.

MR. JOSEPH F. PORTER has been appointed Medical Officer of Health for the rural district of Helmsley.

DR. PETER FRASER has been appointed Medical Officer of Health for the urban district of Llanrwst.

DR. HARRISON has been reappointed Medical Officer, and Mr. A. J. Catt Inspector of Nuisances, for Sandwich.

DR. HENRY FAWCETT has been appointed Medical Officer of Health for the rural district of Middlesbrough.

THE offices of Reeves' Chemical Sanitation, Limited, have been removed to 17, Victoria-street, Westminster, S.W.

MR. JOS. EVANS and Mr. W. R. Evans, of Traffgaent, have been elected Surveyors to the District Council of Haverfordwest.

THE Local Government Board has sanctiond the appointment of Mr. Statham as Sanitary Inspector for the urban district of Haywards Heath.

MR. E. S. TRUMAN, who has been acting as Deputy Surveyor to the Pottersbury Rural District Council, was on Thursday last unanimously elected to the permanent post.

MR. TOM VICKERS, Surveyor of Newark Rural District Council, has been appointed Surveyor to the Bexley Urban District Council. There were 119 applicants for the post.

DR. R. W. SOPER has been reappointed Medical Officer, and Mr. T. Veale Sanitary Inspector, to the Dartmouth and Totnes Port Sanitary Authority at the same salaries as before.

WE are requested to state that the announcement of the appointment of Dr. Chawner as Medical Officer of Health of the urban district of Clay Cross was premature. Dr. Chawner has been appointed Medical Officer to the Clay Cross district of the Chesterfield union, but not to the urban district.

Sewerage Schemes.

[TO MUNICIPAL ENGINEERS AND SURVEYORS.—The Editor will be pleased to receive items for publication relating to sewerage schemes projected or inaugurated, together with explanatory diagrams or photographs. The former should be drawn and lettered in black ink.]

AT a recent meeting of the Ogmore and Garn Council the Committee appointed to inspect systems of drainage in other towns recommended the adoption of the septic system. The Local Government Board had written sanctioning the septic tank system, subject to certain conditions being observed. It was finally agreed that the Surveyor prepare an estimate of the cost, and that the Clerk inquire the Septic Syndicate's terms.

MR. H. C. STEPHENS has introduced a Bill to enable Local Authorities to deal separately with the sewage and drainage of their districts.

IN consequence of an application by the Portishead Urban District Council for sanction to borrow £3000 for purposes of sewerage, a Local Government Board inquiry was held last week.

THE Bakewell Rural District Council has decided to apply to the Local Government Board for sanction to borrow the sum of £900, on account of the Little Longstone works, and £2600 for the Winster scheme.

THE work connected with the drainage of Westgate was commenced last week. Surface drains will soon become a thing of the past, and the village consequently more up to date in regard to sanitary arrangements.

THE Trowbridge Urban District Council has agreed to ask Bradford-on-Avon District Council —both these Authorities being faced with the sewage disposal difficulty—to join in experimental work for testing the bacteriological principle.

A LOCAL Government Board inquiry was held recently at Bewdley relative to a complaint lodged with the Board by the Worcester County Council, that the Town Council of Bewdley had made default in providing the borough with a supply of water and sufficient sewers.

A LOCAL Government Board inquiry has been held at Shifnal (Salop) in respect of an application made by the Council to borrow a sum of £3300 to carry out a drainage and sewage disposal scheme prepared by Mr. Edward W. Ives, C.E., of Derby, and £3745 for a water scheme. The inquiry was adjourned.

THE Devizes Corporation has been informed that samples of effluent coming from its sewage works were very far from satisfactory. The explanation given by the Surveyor is that owing to the insufficiency of the main outfall sewer to take storm water, a quantity of crude sewage recently found its way to the brook.

A LOCAL Government Board inquiry was held recently at Rugby with reference to the application of the Urban District Council to borrow £2650 for the purchase of land for sewage disposal purposes, £1920 for a new fire engine station, £770 for an improved outfall sewer, and £2500 towards the cost of erecting new public offices.

A LOCAL Government Board inquiry has been held at Dalkey in respect of an application by the Commissioners for a loan of £700 to enable them to carry out certain sewerage works in the township. Mr. Walsh, who prepared the plans of the sewers proposed to be constructed, was examined, and estimated the cost at about £630. The sewers were badly wanted in the district.

THE Chester-le-Street Rural District Council has instructed Messrs. D. Balfour and Son, of London and Newcastle, to report on a scheme of main sewerage for Chow Dene, Wrekenton, Eighton Banks, and Team Colliery, in the township of Lemesley, to be connected with the western sewer of the Corporation of Gateshead.

AT the last monthly meeting of the Dufftown Commissioners the question of disposal of the burgh sewage was again considered, and Mr. Gordon, C.E., Inverness, who had been engineer to the Commissioners when the scheme was carried out in 1881, was appointed to make a report and plan to be submitted to the next monthly meeting.

THE Derby Town Council at the conclusion of its last meeting resolved itself into a committee to consider the latest phase of the sewage question. The Mayor reported the result of his negotiations with Lord Waterpark with regard to the proceedings threatened by the County Council. A subcommittee was appointed to confer further with the County Authorities for the final settlement of the terms of the proposed order.

THE Local Government Board has written the Epping District Council stating that the scheme of sewerage and sewage disposal for Theydon Bois (in respect of which the Council wished to borrow £1800) was generally satisfactory, but arrangements should be made at the outfall for pumping the sludge from the proposed sludge pits to the settling tanks for treatment. Further, a provisional agreement should be entered into for the acquisition of the sewage disposal land on lease for a period of not less than thirty years.

THE Provisional Order applied for by the Rural District Council of Blaby for power to acquire lands for the disposal of the sewage of Enderby, recently came before the chairman of the Commons' Committee of Ways and Means. The Council proposes by this order to acquire seven acres of land on the eastern side of the Narborough and Enderby Railway, owned by Mr. Charles Smith, and occupied by Mr. Thomas Muddimer, with the right of way over an occupation road to the land to be purchased. The order was confirmed.

THE four experts to whom the Manchester Corporation referred its scheme of sewage disposal, Mr. Baldwin Latham, Dr. Percy, Mr. F. Frankland, and Professor Perkin, have issued formal notice that they have undertaken the duties entrusted to them. The four gentlemen named were also requested and authorised to advise as to any alternative scheme which might be put before them, and they now give notice that they are prepared to receive written communications setting forth any scheme that may be suggested for their consideration. At the same time it is distinctly stated that no premium is offered, nor will any expenses be paid in respect of any scheme so submitted. The experts have made an inspection of the Davyhulme Sewage Works.

THE Doncaster District Council has resolved that a sewage scheme for Adwick-on-Dearne, prepared by Mr. Barrass, estimated to cost £335, be laid before the parish meeting, and a sewage scheme for Adwick-le-Street, to cost £547, is to be submitted to the Parish Council for that place.

THE Local Government Provisional Orders (No. 8) Bill recently came before the Unopposed Committee of the House of Commons. The object of the measure is to confirm certain Provisional Orders of the Local Government Board, one of which enables the Urban Sanitary Authority for the City of Nottingham to compulsorily acquire certain lands for the disposal of the sewage of the city. The Bill was passed through the committee stage, and ordered to be reported for third reading.

A LOCAL Government Board inquiry has been held at Mirfield respecting the District Council's application to borrow £5800 for purposes of sewage and sewage disposal, £1547 17s. 6d. being the estimated cost of the drainage of the Upper Hopton district, and £4252 2s. 6d. for a proposed new effluent sewer at the sewerage farm, Ravensthorpe, to underdrain the whole of the land required (33½ acres) for sewage disposal purposes. Dr. Wilson, Chief Inspector to the West Riding Rivers Board, and one of his assistants were present at the inquiry, and said the Council had been pressed to carry out the works because they were turning crude sewage into the stream which had passed over the sewage farm land instead of through it. Mr. Thompson, solicitor, Mr. E. H. Clare (land surveyor and agent to the estate) and Mr. C. Cott, C.E., appeared on behalf of Lady Montgarrett's trustees, through whose land the proposed effluent sewer would pass, but they withdrew their opposition to the scheme on the understanding that the necessary protection clauses and stipulations as to easements would be inserted in the agreement to be made between the parties.

Lighting.

THE Urban District Council of Teignmouth has decided to lay a 14in. gas main, and to invite tenders for the loan of £2000 to carry out the work.

AT a recent meeting of the Town Council of Ryde the question of the electric light was discussed, and the Mayor, amidst applause, promised to call a meeting of the townspeople to consider it.

THE Worthing Corporation has agreed to the early introduction of the electric light into the borough, but will require the contractors who are ultimately selected to work the undertaking at a stipulated rental for five or seven years.

THE annual meeting of shareholders in the Milngavie Gas Company has been held. The profit during the year is £397, and after paying the usual 5 per cent. dividend there is a good balance carried forward to meet the extra expenditure in the future.

AT the last meeting of the Shrewsbury Town Council a motion was carried instructing the Town Clerk to make application to the Local Government Board to sanction a loan of £35,000 for the purchase of the undertaking of the Shropshire Electric Light and Power Company and to carry out extensions.

THE directors' report of the Hawick Gas Light Company has been issued, and it shows the past year to have been a prosperous one, for after paying a dividend of 10 per cent. there will be a balance carried forward. The profit for the year amounted to £1930 17s. 4d. The directors recommend that the price of gas be continued at 3s. 4d. per 1000 cubic feet.

AT a recent meeting of the Dunfermline Gas Commission, it was stated that the profit on the past year's working of the gasworks amounted to nearly £3000. The Gas Committee had decided to reduce the price of gas from 3s. 7d. to 3s. 6d. per 1000 cubic feet, and to reduce the charge for meters by one-half.

IT is reported that the Midland Electric Light Company has given formal notice to the Town Clerk of its intention to again apply to Parliament for statutory powers for supplying Leamington with electricity for lighting purposes. The Leamington Corporation is at the present time promoting an Electric Lighting Order for this same purpose.

A SPECIAL meeting of the Town Council of Glossop was held last week to consider a scheme for lighting the borough with electricity. The scheme submitted comprised an electric station and works on a site adjacent to the Glossop Iron Foundry, from which centre the electric light would be supplied throughout the borough. The street lighting along the route would be electric, and the existing pillars would be utilised in most of the streets. The cost of working, maintenance, rent of site, and redemption and interest of capital would be about £1975 per annum, and the income would be, per 4000 lamps, about £2000, which would give a clear margin of £25 profit. The capital estimated to be expended is about £15,000. It was decided to adjourn the subject for a month, in order that the probable consumers could be canvassed on the subject.

THE Birmingham City Council has decided to purchase the undertaking of the Birmingham Electric Supply Company, Limited, at a cost of £420,000, and to promote a Bill in Parliament next session for lighting the streets by means of electricity. The shares of the company to be purchased were floated at £5, but the Corporation has agreed to buy at ten guineas per share, and to take over all assets and liabilities of the company as a going concern from January last. The profits of the company last year were over £12,000. On Tuesday last a meeting of the shareholders of the Birmingham Electric Supply Company was held to consider the proposed sale of the undertaking to the Corporation. It was decided almost unanimously to approve of the sale, and request the directors to make the necessary arrangements for carrying the agreement into effect. It was also decided to grant the directors £2000 for their services.

On Thursday, the 16th inst., at a meeting of the St. George's (Hanover-square) Vestry, Mr. G. W. Smith moved that a special committee of twelve members be appointed to consider the best means of lighting the parish by electricity, and to approach the electric light corporations. He said it was strange that the richest parish in the world should be so behind others in introducing electric light. Although, perhaps, it was no use going into the past, he could not help mentioning that the ratepayers had lost a great opportunity of making a good profit for themselves in allowing private companies to get a footing in this parish. However, he hoped the Vestry would now rouse itself and light its streets by electricity, which would give a clear light and be a great public convenience and benefit. At present the streets, especially in the out ward, could scarcely be said to be lighted, as there it was "darkness made visible." He felt sure the companies would meet the Vestry in a liberal spirit. Mr. Macdonald seconded the motion, and it was carried unanimously, and a strong Committee was appointed, consisting of Lord Hobhouse, Colonel the Hon. H. Legge, Mr. R. C. Antrobus, L.C.C., Mr. Bradford, Mr. Macdonald, and others.

SIZE AND WEIGHT OF MICROBES.

In the theatre of the Royal Institution, Dr. E. E. Klein, lecturer on physiology at St. Bartholomew's Hospital, gave the first of two lectures on "Achievements in Bacteriology." In the course of his remarks the speaker quoted some remarkable statistics concerning the microbe and its manners. Its dimensions were so insignificant, he said, that a postage stamp would accommodate 500,000,000 of the species which wrought so much destruction at Maidstone. Their fecundity was prodigious, so much so that if fifteen drops of water polluted with bacteria were allowed to fall into a cup of broth the germ population would have increased in twenty-four hours to 80,000,000. So profound had been the researches of the scientists who made this matter a special study, that not only had the bacteria associated with various diseases been discovered—photographs of the different kinds were shown on the screen—but their weight had been estimated. As an instance of this fact Dr. Klein said that it would take 122,000,000 specimens of *Bacillus typhi abdominalis* to weigh a gramme. So penetrating had been the studies of the bacteriologist that he could now detect one part of sewage even if it was contained in as many as 500,000 parts of water.

THE PURE BEER QUESTION.

(*To the Editor of* The Sanitary Record.)

Sir,—I note with interest your article on this subject, particularly that part which refers to Mr. Cassal's evidence as to the analogy, so far as regards mercantile rectitude, with the case of margarine sold as butter. I would somewhat amplify the demands upon the vendor of beer. The purchaser should have guaranteed to him, not only imperial measure, but also imperial constituents; these should be the products of the fermentation of barley malt flavoured with hops. Seeing that there are other matters from which alcohol can be obtained, it may well be permitted that liquors not made entirely from malt and hops shall be legally vended as ales. In such a case the man who chooses a glass of ale to a half-pint of beer is in no sense defrauded.—Yours faithfully,

Arthur Angell.

Notes and Queries.

[Subscribers have the privilege of obtaining advice in this column on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed to The Editor, "Notes and Queries," The Sanitary Record, 5, Fetter-lane, London, E.C.

Note.—If an answer be required immediately, a stamped addressed envelope must be enclosed, when we will endeavour to furnish a copy of the answer by post, as owing to the large number of queries received we cannot guarantee the insertion of a reply in the succeeding issue.

1123.—Rain Water from Roofs of Houses: When a Nuisance.—"H. S. H." writes:—"What authority have Sanitary Inspectors to enforce the conveyance of rain water from old cottage roofs and other buildings? Is it imperative that all eaves should have proper gutters and drain pipes, and would it not entail the provision of a system of drainage for the same?"

Answer.—In rural districts, where any existing house is without a rain-water shoot, and owing to the absence of such the walls or foundations of the house are rendered damp, such a condition constitutes a nuisance within the provisions of Sec. 91 of the Public Health Act, 1875, and notice may be served under Sec. 94 to abate the same by providing rain-water shoots with fall pipes, the same to be connected to a drain by being made to discharge over a trapped gully. It is rarely necessary or advisable to provide a separate system of drainage for the disposal of roof water in rural districts, the drain from the rain-water shoot should be connected to the drain receiving slop-water.

1124.—Inspector of Nuisances and Sanitary Inspector: Description.—"W." writes:—"Will you kindly inform me whether there is any difference in the offices of Sanitary Inspector and Inspector of Nuisances?"

Answer.—No. The description or title "Inspector of Nuisances" and "Sanitary Inspector" have the same meaning. In the Public Health Act, 1875, the officer is designated "Inspector of Nuisances," and the more euphonious title of "Sanitary Inspector" does not occur. In legal proceedings it therefore follows that the title, "Inspector of Nuisances," must be used. It is generally recognised that this title should be changed to Sanitary Inspector, as although in the Public Health Act, 1848, this officer was a mere inspector of nuisances, his duties have been so extended that the title is now inadequate. The Legislature having recognised this, the officer is described in the more recent Public Health Acts, viz., The Public Health (London) Act, 1891, and Public Health (Scotland) Act, 1897, as Sanitary Inspector, and the older title has been abolished.

1125.—Clerks of Works and Association of Clerks of Works.—"C. R. T." writes:—"Will you kindly inform me what knowledge, accomplishments, or certificates are required in order to obtain employment as clerk of works to an Urban District Council. I have

recently passed the Sanitary Institute examination, and am now studying building construction. Is there a Clerk of Works' Association? If so, any information respecting the same would be appreciated."

Answer.—Urban District Councils do not generally appoint as a permanent official a clerk of works. Such an official is, however, appointed to see to the execution of contracts of importance, such as sewerage works, sewage farms, and for expensive buildings when in course of construction. Candidates for such appointments must have had considerable practical experience of such work; must understand plans, and be able to set out the work accurately on the site, and keep the contractor's foreman from making mistakes, and workmen from doing improper work. He must be able to distinguish readily between good and bad materials, so that inferior stuff may be rejected promptly. He should be able to furnish detailed plans of portions of the work if called upon; must be able to write well, measure up work, and test all materials which come upon the site. There is a Clerk of Works' Association, which has its offices at 4, Ham Park-road, Stratford, London, E., the secretary of which is Mr. J. Brady. The conditions of membership are as follows: (1) The candidate must be a bonâ fide clerk of works, and (2) must have been engaged as clerk of works (exclusively) for the last three years, or for four years at some former period. The candidate must also fill up a form stating the works upon which he has been engaged, and the names of the architects of those works. He must be proposed and seconded by members, and balloted for at a meeting of the Association, when one black ball in ten excludes. The Association publishes a journal of its own.

1126.—KEEPING FOWLS: NUISANCE.—"X. Y. Z." writes: "A friend of mine has just received a notice from the Inspector of Nuisances, worded as follows:—'The Mayor, Alderman, &c. &c., being satisfied of the existence of a nuisance arising from fowls and pigeons kept so as to be a nuisance to your neighbours, do hereby require you to abate, &c., and for that purpose to remove fowls and pigeons, and discontinue keeping the same so as to be a nuisance.'

"The pigeon loft and fowl-houses are scrupulously clean and limewashed. Has Mr. D. any cause for complaint if the fowl run is taken away, allowing 9ft. space between the end of run and dwelling-house? Should the now unoccupied house as shown in sketch become occupied, would there be cause for complaint, as it would be only 6ft. from their back door?

"C. is quite willing to do away with his fowls altogether, but desires to keep his pigeons. I have suggested to him that he should take down the run altogether, and re-fix his loft in the garden as marked, leaving about 14ft. clear of his loft away from either D. or F. Is my contention right that they cannot interfere with him so long as he keeps his place clean? What construction do you place on the word 'remove?'"

Answer.—If the buildings wherein the fowls are kept are maintained in a perfectly cleanly condition, we do not think the Local Authority will be able to interfere. The nuisance is not such a one as can be removed under the provisions of the Public Health Acts, and it appears to us that the notice served by the Inspector of Nuisances is not in order. We have no doubt the word "remove" as used in the notice is intended to mean abolish or cease keeping the fowls, &c.

1127.—CUBIC SPACE AND VENTILATION: ACTS HAVING REFERENCE THERETO.—"B. S." writes:—"What Acts relating to cubic space and ventilation exist which concern an Inspector of Nuisances; and is there any regulation for cubic space and ventilation on seagoing vessels, and what are they?"

Answer.—The provisions of the Acts having reference to cubic space and ventilation are as follows:—As to common lodging-houses: A Local Authority are required by Sec. 80 of the Public Health Act, 1875, to prescribe the number of lodgers which may be allowed to inhabit any room therein, and to enforce ventilation. The Local Government Board recommend that not less than 300 cubic feet per head be allowed for each individual. As to dwelling-houses: Any house or part of a house, and any tent, van, or shed which is so overcrowded as to be dangerous or injurious to the health of the inmates, whether or not members of the same family, is a nuisance as defined by Sec. 91 of the Public Health Act, 1875. And by bye-laws as to new streets and buildings, made under Sec. 157 of the Act, the Local Authority are enabled to provide for the ventilation of dwelling-rooms to new houses by enforcing a window area to each habitable room equal to one-tenth the floor space, and that at least one-half the window shall be made to open. As to workshops:—By the Factory and Workshop Act, 1895, the minimum cubic space to be provided per head must be not less than 250ft., and 400 cubic feet for overtime. As to cowsheds: Under the Dairies, Cowsheds, and Milkshops Order of 1886, a Local Authority may enforce the provision of sufficient cubic space for cows, the amount enforceable, it has been decided, being not less than 800 cubic feet per head. As to seagoing vessels: Under the Merchant Shipping Acts a cubic space of 72ft. per head has to be provided. Inspectors of Nuisances have, however, no supervision over seagoing vessels.

1128.—VELOCITY IN AND DISCHARGE OF SEWERS: BOOK ON: RECOMMENDED.—"H. T. S." writes:—"Can you recommend me a work giving the various velocities of sewage in sewers? What I require is a book showing what is the velocity and discharge from sewers when the diameter is known. I require it for checking my workings by formulæ, as I am preparing for the examination of the Municipal Engineers' Association. I have Neville's "Hydraulic Tables," but they are not clear enough for a beginner."

Answer.—An excellent book for the purpose required by our correspondent is Crimp and Bruges' "Tables and Diagrams for Use in Designing Sewers and Water Mains," price 10s. 6d., obtainable from The Sanitary Publishing Company. This book gives the velocity and discharge of sewers at all rates of inclination in a highly convenient and lucid form. In another answer we give the formulæ most commonly used for determining the velocity and discharge of circular sewers.

1129.—ORDNANCE DATUM: MEANING OF TERM.—"Student" writes:—"What is the meaning of the term 'Ordnance datum?' It is often expressed as so many 'feet above Ordnance datum.' Does it mean as so many feet above the bench-marks on buildings, &c.? Is there a small work published, explaining the Ordnance maps and terms used in connection with same?"

Answer.—The Ordnance Datum of this country was determined by the Ordnance Authorities to be "the approximate mean water at Liverpool." All the levels marked upon the Ordnance maps are the altitudes in feet above this datum, so that in the north of Scotland or in Wales, equally with Southampton or Yarmouth, all over the kingdom, whenever a figure preceded by a dot, thus, ·33·6 or ·336·0, is upon a map, it shows in the one case 33ft. and $\frac{6}{100}$ths of a foot, and in the other case 336ft. above this datum respectively. It must be observed, however, that it is neither usual nor necessary to adopt the Ordnance Datum in ordinary building operations, but to assume some convenient depth below the lowest point of the section, the reason for which is that all altitudes shall be above this datum, so that they will always have a positive, and never negative heights. The following books, which are published by the Ordnance Survey Department, will be useful, viz.:—(1) "Explanatory Remarks on the Character of Type, Abbreviations, Symbols, Areas, &c.," price 6d.; (2)

"Characteristics of Writing and Boundaries, used on the 1in. and 6in. Maps of Great Britain," price 6d.; (3) Characters for the Writing of the Names and Symbols for the Indicating of Boundaries on the 10ft., 25in., and 6in. Maps," price 6d. Any of the books may be obtained from the Sanitary Publishing Company, post free, for 6½d. each.

1130.—VELOCITY AND DISCHARGE OF SEWERS.—"H. S. T. writes:—"Will you please oblige me with particulars as to what would be the velocity and discharge of a (1) 9in. and (2) a 12in. circular sewer respectively, having a fall of 1 in 1000 running half full?"

Answer.—One of the simplest and most commonly used formulæ for obtaining the velocity in circular sewers is Eytelwein's, and is as follows:—

$v = 55\sqrt{2hf}$, where

v = velocity of flow in feet per minute;

h = hydraulic mean depth in feet (which in sewers running full or half full is one-fourth the diameter,

f = fall in feet of sewer per mile.

Taking the cases given by the querist, and applying the formula, we have for a 9in. sewer

$v = 55\sqrt{2 \times \cdot1875 \times 5\cdot28}$, and

$v = 55\sqrt{1\cdot98}$, and

$v = 55 \times 1\cdot4$, and

v = 77ft. per minute, which is the velocity in a 9in. sewer, having a fall of 1 in 1000.

For a 12in. sewer we have

$v = 55\sqrt{2 \times \cdot25 \times 5\cdot28}$, and

$v = 55\sqrt{2\cdot64}$, and

$v = 55 \times 1\cdot624$, and

v = 89·3ft. per minute, which is the velocity in a 12in. sewer, having a fall of 1 in 1000.

Having obtained the velocity of sewage, the discharge is obtained by the formula

D = V × A, where

D = Discharge in cubic feet per minute;

V = Velocity in feet per minute;

A = Cross sectional area of flow (*i.e.*, diameter squared × ·7854). In the case of a 9in. pipe running half full the discharge will be $\left(\frac{\cdot75 \times \cdot75 \times \cdot7854}{2}\right) \times 77$ (velocity in feet per minute) = 17 cubic feet per minute discharge.

In the case of a 12in. pipe running half full the discharge will be $\frac{1 \times 1 \times 7854}{2} \times 89\cdot3$ (velocity in feet per minute) = 35·06 cubic feet.

1131.—THE DIBDIN OR SUTTON SEWAGE SYSTEM.—"S. T. H." writes:—"Can you kindly explain the Sutton or Dibdin (as it is sometimes termed) system of sewage treatment?"

Answer.—The Sutton or Dibdin system of sewage treatment consists in passing crude sewage (from which floating paper only is screened) without previous chemical treatment into artificial filters composed of burnt clay, ballast, clinkers, coke, or other hard and coarse material, from which the finer material (below ¾in. gauge) has been rejected. The filter is provided with a main underdrain to which a valve is affixed for closing the outlet when the filter is at work. The sewage is applied intermittently, the filter being charged, and the sewage is allowed two hours contact, after which the valve is opened, the sewage is drawn off, and the filter is then allowed two or more hours' rest for aëration. By this treatment the major portion of the sewage is absorbed by the agency of bacteria present in the filter. The effluent from the coarse filter is then run on to another filter, similar in construction to the first, except that it is of fine grain, for final treatment, the filtrate resulting therefrom being of remarkable purity as compared with effluents from most processes of sewage purification. For further particulars of the system, see Dibdin's "Purification of Sewage and Water," 21s., Sanitary Publishing Company.

Contracts Open.

The dates given below are the latest up to which tenders can be received.

HAMSTERLEY (NEAR BISHOP AUCKLAND).—June 24th—July 4th.—Sewer.—Mr. C. Johnston, surveyor, 1, Cradock-street, Bishop Auckland.

LEAMINGTON SPA.—June 27th.—Urinal.—The Borough Engineer, Town Hall.

RAWTENSTALL.—June 27th.—Drains.—Mr. A. W. Lawson, A.M.I.C.E., borough surveyor, Municipal Offices, Rawtenstall.

SALE.—June 29th.—Sewers, &c.—Mr. Alexander G. M'Beath, C.E., 4, School-road, Sale.

TANFIELD (DURHAM).—June 29th.—Sewers.—Mr. Robt. Heslop, surveyor, Burnopfield.

KEIGHLEY.—June 30th.—Sewer.—Mr. W. H. Hopkinson, borough engineer, Keighley.

ALTON (HANTS).—July 1st.—Sewers, &c.—Messrs. R. B. Grantham and Son, 23, Northumberland-avenue, London, W.C.

BRIERFIELD.—July 2nd.—Sewer.—Mr. James T. Landless, A.M.I.C.E., Station-buildings, Nelson.

ETON.—July 2nd.—Sewer, &c.—Messrs. Bailey, Denton, Son, and Lawford, Palace-chambers, Westminster.

CAERPHILLY.—July 4th.—Sewer.—Mr. A. O. Harpur, surveyor, Council Offices, Caerphilly.

WHEATHAMPSTEAD.—July 5th.—Sewers.—Mr. T. Foster Woodman, F.S.I., St. Albans.

HONLEY (HUDDERSFIELD).—July 19th.—Sewerage Works.—Mr. W. H. Radford, C.E., Angel-row, Nottingham.

HONLEY (HUDDERSFIELD).—July 19th.—Sewer.—Mr. W. H. Radford, C.E., Angel-row, Nottingham.

Vacancies.

ASSISTANT INSPECTOR (WESTON-SUPER-MARE, July 2nd).—For the Urban District Council. Salary, £1 per week. Mr. Sydney C. Smith, clerk, Town-hall, Weston-super-Mare.

BOROUGH SURVEYOR (BACUP, July 6th).—For the Town Council. Salary, £200 a year. Mr. Robert Hyde, town clerk, Bacup.

DRAUGHTSMAN.—Salary, £2 per week. Mr. R. S. Rounthwaite, A.M.I.C.E., borough engineer, Town Hall, Sunderland.

DRAUGHTSMAN (SALFORD, June 24th).—Mr. Samuel Brown, town clerk, Town Hall, Salford.

INSPECTOR OF NUISANCES (SWANSEA, June 27th).—For the Town Council. Salary, 25s. per week. Mr. John Thomas, town clerk, Guildhall, Swansea.

SANITARY INSPECTOR (PLUMSTEAD, July 11th).—For the Plumstead Vestry. Salary £104 per annum, rising by increments of £6 for one year after Lady Day, 1899, and £5 per annum afterwards to £130 per annum. Mr. Edwin Hughes, vestry clerk.

SURVEYOR, &C. (ECCLESHILL, YORKS, June 27th).—For the Urban District Council. Salary, £130 per annum for the combined offices. Mr. Jos. Richardson, clerk, Eccleshill, near Bradford.

SURVEYOR, &C. (ITCHEN, June 28th).—For the Urban District Council. Salary, £125 per annum, increasing to £150 within three years. Mr. William Henry Bell, clerk, Woolston, near Southampton.

SURVEYOR'S TEMPORARY ASSISTANT (ARDSLEY, June 27th).—For the Urban District of Ardsley East and West. Wages, 26s. per week. Mr. R. Borrough Hopkins, clerk, Prudential-buildings, Leeds.

WATERWORKS ENGINEER (LINCOLN, July 16th).—For the Corporation. Salary at the rate of £250 per annum. Mr. H. K. Hebb, deputy town clerk, Lincoln.

COMPETITIONS.

LINSDALE, July 1st.—Sewage Disposal and Water Supply. — The Linsdale Urban Council invite plans, specifications, with estimates for dealing with the sewage disposal and water supply for the above-named district, such plans and estimates to be sent to Mr. R. I. Platten, clerk, Linsdale, Leighton Buzzard, by July 1st, marked with a motto or *nom de plume*, and endorsed "Linsdale Sewerage and Water Supply."

To Medical Officers, Surveyors, Sanitary Inspectors, &c.—High-grade Cycles at reasonable prices for prompt cash and on the GRADUAL PAYMENT SYSTEM. Catalogue post free.—MELROSE CYCLE COMPANY, Coventry.

THE annual meeting of the Incorporated Association of Municipal and County Engineers opens on Thursday next at Edinburgh. A varied and interesting programme has been provided, including the discussion of papers on important problems of municipal engineering. The president is Mr. O. Claude Robson, M.I.C.E., of Willesden.

SANITARY HOTELS AT HOLIDAY RESORTS.

CO-OPERATION OF READERS REQUESTED.

IN accordance with an announcement made in previous issues of THE SANITARY RECORD, we are prepared to examine and report upon the sanitary condition of Hotels and Boarding Houses at Holiday Resorts, and if the examination is satisfactory, to issue a certificate to that effect. Sanitary Inspectors and others are invited to co-operate with us in this matter, and we shall be pleased to forward particulars to any such who may care to do so. We are not asking for gratuitous assistance, but are prepared to adequately recompense sanitary workers who may interest themselves in our enterprise

SANITARY ASSOCIATION OF SCOTLAND.

EXAMINATIONS IN SANITARY SCIENCE.

Examinations for Certificates of Competency in Sanitary Science are held each year as follows, viz.:—In Glasgow in April, in Edinburgh in October, and at such other time and place as the Board of Examiners may determine.

Entrance Fee £2 2s.

For further particulars apply to

GEORGE MIDDLETON, M.A., LL.B.,
Writer, 92, Bath Street, Glasgow,
Secretary to the Board of Examiners.

A Stamped Addressed Envelope must accompany all letters requiring an answer.

SANITARY INSTITUTE EXAMINATIONS.

TUITION BY CORRESPONDENCE.

An Engineer and Surveyor (Mem. San. Inst.), Certificated Surveyor and Inspector, prepares students for these Exams. by Correspondence through the post.

Fees strictly moderate. Cramming studiously avoided.

The course of tuition is arranged so as not only to qualify the student for passing the exams., but what is of equal importance, viz., that he may become a thoroughly efficient Inspector.

On successfully passing the exams., all possible assistance and advice is given to help forward intending candidates for public offices.

Many of my old pupils are now filling positions with salaries of over £120 a year.

For terms, &c., address "C. E.," care SANITARY RECORD, 5. Fetter-lane, London, E.C.

SANITARY INSTITUTE EXAMINATIONS.

SPECIAL Corresponding Classes for the **Practical Sanitary Science,** and **Sanitary Inspectors' Examinations** of the **Sanitary Institute, 1898,** conducted by a gentleman holding appointments as Urban District Council Engineer and Sanitary Inspector, holder of three certificates from the Sanitary Institute, First-class Honour Medallist Hygiene, &c. Hundreds of successes.—For all particulars, testimonials, &c., apply Mem. San. Inst., Office of THE SANITARY RECORD, 5, Fetter-lane, London E.C.

OFFICIAL ADVERTISEMENTS.

CITY OF NORWICH.—The Corporation of Norwich requires an ASSISTANT INSPECTOR of NUISANCES, who must hold the Certificate of Competency in Sanitary Knowledge of the Sanitary Institute, London.

Preference will be given to one who has had practical experience.

Salary £70 per annum.

Uniform will be provided.

Applications, endorsed "Inspector of Nuisances," with three recent testimonials, to be sent to me on or before 9th July next.

GEO. B. KENNETT,
Town Clerk.

Guildhall, Norwich,
13th June, 1898.

THE ECCLESHILL URBAN DISTRICT COUNCIL require a SURVEYOR and WATER-WORKS MANAGER and INSPECTOR of NUISANCES, who will have to devote the whole of his time to the duties of the offices.

Salary £130 per annum for the combined offices.

The selected candidate will be required to commence his duties forthwith upon appointment, and to reside within the district.

Candidates must be between the ages of 25 and 40 years.

Applications, stating age and experience, should be made by letter, addressed to the undersigned, and marked outside "Surveyor," not later than Monday, June 27th, 1898, accompanied by recent testimonials, not more than three in number.

JOS. RICHARDSON,
Solicitor and Clerk to the Council.

Eccleshill, near Bradford.

URBAN DISTRICT OF BARKING TOWN, IN THE COUNTY OF ESSEX.

ASSISTANT SANITARY INSPECTOR.

The Council invite APPLICATIONS for the POST of ASSISTANT SANITARY INSPECTOR for the District.

Applicants must hold a Certificate, and be duly qualified. The person appointed will be required to live in the District, and devote the whole of his time to the duties of the office.

Commencing salary £104 per annum, subject to the sanction of the Local Government Board.

Applications, stating age, present occupation, experience, and qualifications, and accompanied by copies of three recent testimonials, to be sent in to me not later than 5 p.m. on the 5th July, 1898.

Canvassing, either directly or indirectly, will disqualify.

E. H. LISTER,
Clerk to the Council.

Food and Health

SUPPLEMENT TO

THE SANITARY RECORD.

No. 12. JANUARY, 1898.

FOODSTUFFS UNDER SCRUTINY.

WHAT TO EAT AND DRINK, AND WHAT TO AVOID.

"SANITARY RECORD" ANALYSES.

IMPORTANT ANNOUNCEMENT.

OWING to the growing popularity of this feature of our "Food and Health" Supplement, we have found it necessary to make arrangements whereby, in future, much fuller reports will be given of proprietary articles than have appeared hitherto. It has been our custom to solicit samples of articles for investigation from the manufacturers direct, unconditionally; but in future such samples as we receive from the proprietors thereof will require to be accompanied by a declaration that the sample is selected from stock, and not put up for the special purpose of analysis. Failing this we shall make the purchases ourselves, selecting the articles at random from the various retail establishments where they are sold.

We have retained the services of Mr. C. G. Moor, M.A., to examine and report on the various substances submitted to us.

All such analyses may of course be quoted as having appeared in THE SANITARY RECORD, but the date must be given, and Mr. Moor's name must not be quoted for advertising purposes without special permission.

"Index" Rolled Oats.

"I have duly examined the sample of 'Index' Rolled White Oats (Duncan's Patent), manufactured by the Northern Milling Company, Limited, Belfast, with the following results:—

Moisture	9·9
Fat	7·3
Albumenoids	18·9
Ash	2·1
Insoluble Fibre	1·4
Carbohydrates, &c., by difference	60·4
	100·0

These figures are satisfactory evidence of the good quality of the sample.

"The mineral matter contained 0·3 per cent. of phosphoric acid (P_2O_5), calculated on the original sample, or one-seventh of the total ash.

"The percentage of albumenoids present, which are the most important constituents, is above the average for oatmeal, and the figure for the insoluble fibre shows the sample to be very free from husk.

"Microscopic examination proves the sample to be free from extraneous matter. The flavour and appearance leave nothing to be desired, and I am of opinion that these oats are in every respect of excellent quality."

Hay's Frumentine.

"I HAVE examined the sample of 'Hay's Frumentine' prepared by William Hay, Limited, manufacturing chemists, Hull, with the following results:—

Water...	12·3
Fat	4·6
Ash	2·7
Insoluble fibre	2·1
Albumenoids	21·3
Carbohydrates, &c, by difference...	57·0
	100·0

"The mineral matter or ash contained nearly one-third of its weight of phosphoric acid calculated as P_2O_5, while the high figure, 21·3 per cent., representing the albumenoids, shows that a large proportion of 'germ' must enter into the composition of this food. As much as 14·3 per cent. of the food is soluble in cold water, and this fact, taken in conjunction with those above mentioned, is sufficient to give it a high place among foods of this class.

Digestibility of Eggs.—Eggs are digestible when they are lightly cooked or uncooked, indigestible when hard boiled. They are also more digestible when they are beaten than when they are cooked in the shell. But not eggs only, every food is more easily digestible when it is vesiculated than when it is solid, and, therefore, penetrated with difficulty by the digestive fluids. An egg should be beaten and lightly cooked for an invalid. The quality of the egg varies with the food of the fowl. Hens' eggs are commonest and also best for cooking purposes. Ducks', guinea-fowls', plovers', and other eggs are esteemed for the table; but they are ill adapted for puddings and custards, because the white is transparent and soft and does not set firm. The eggs of reptiles—*e.g.*, the turtle—are also eaten.

DISEASED AND UNWHOLESOME MEAT.*

By T. Robinson.

The following notes are written with the view of drawing the attention of general practitioners to the subject of meat in its relation to disease. I have drawn upon my personal experience whenever I have been able to do so, but lay no claim to originality in either matter or treatment. In the following table good meat is broadly distinguished from bad, but it must be understood that the goodness here is simply that of meat the healthy nutrition of which has not been impaired, while the badness is that of the exact converse. Beef is the flesh specially described, but the standard may be applied to other flesh with slight variations:—

BEEF.

"Good" Meat.	*"Bad" Meat.*
COLOUR.	
Bright red, "marbled" with fat.	Dusky red or pale, or both; brownish or discoloured patches; or may be even greenish if putrefactive.
No hæmorrhagic spots.	Hæmorrhagic spots frequent.
FAT.	
Firm, whitish, with tinge of yellow. Not blood-stained.	Soft, unset, as a rule yellow, and often stained or studded with hæmorrhagic spots.
Containing no jelly or watery juice.	May contain jelly or watery juice.
SMELL.	
Fresh and not unpleasant.	Sickly, offensive, or of drugs.
TO TOUCH.	
Firm and elastic. Not wet or sticky. No pitting or cracking on pressure.	Soft, easily torn, wet or sticky. Pitting on pressure.
JUICE.	
Bright red in colour; sweet and fresh to smell.	Dark in colour, or very pale, with bad odour.
TASTE.	
Pleasant.	Absent, or unpleasant.

Horse flesh is of a dark purple colour, has a peculiar sickly odour, and is not "marbled" with fat; the muscular fibres are much coarser, and the fat a greasy yellow.

Calf flesh is paler, and not so firm to the touch as beef flesh.

The flesh of the pig is also paler and less firm, and the fat softer than that of the beast.

Good mutton is in colour a duller red, is firm, and has a hard, white fat.

I shall now proceed to describe in detail some of the special causes of unwholesomeness in butcher's meat.

Tubercle is the most important, and the most common of the diseases of animals, and is therefore considered first and separately. So common is it among animals the flesh of which come under the head of butcher's meat, that I should say quite 75 per cent. of all meat "seized" under the Public Health Acts is condemned on account of it. It is found most frequently in the lungs, pleura, lymphatic glands, liver, peritoneum, omental fat, and kidneys, in the order named. Seldom, if ever, is a case of tubercle found in which the lungs are not affected, but it has been estimated by McFadyean that only 3 per cent. of beasts suffering from tubercle have that disease affecting the udder. Oxen, swine, and sheep suffer most frequently in the order named.

The disease usually shows itself in the form of nodules or caseous masses, varying in size from that of a pin's head to an orange, in the lungs, the liver, kidneys, and lymphatics; but the peritoneum and pleura are generally studded with hard nodules, giving rise to the terms "grapes" and "pearls" in use among farmers and butchers. The nodules or knots are by some called "kernels," but kernel is the name generally used by butchers for a lymphatic gland. Some caseous nodules are hard or calcareous, some softer and breaking down, and some are almost encapsuled and separated from the surrounding tissues. Calcareous particles are almost invariably present in the cheesy tubercle of cattle; among the latter also tubercle is much more prone to form hard calcareous masses than to break down.

The flesh of animals suffering from advanced tubercle is most frequently thin and wasted, and has very little fat; it is dark in colour, sets badly, and is often wet or even dropsical in places; the nutritious quality has without doubt greatly deteriorated—putting aside the fact that it may contain tubercle bacilli or spores—and should therefore be condemned. On the other hand, I have seen, and not uncommonly, animals in good condition, fat and firm, and carrying plenty of flesh, that have had to be condemned after being slaughtered on account of generalised tuberculosis; and in one case—in a beautiful beast—the deep inguinal glands were found to contain small caseous nodules in addition to generalised tubercle in chest and abdomen. It was impossible to tell during life that these animals were suffering from tuberculosis. From this it is clear that animals may suffer from generalised tuberculosis, either in the nodular or caseous form, and yet grow fat, when there is no "breaking down" into pus; but when once the "breaking down" commences, then the condition of the animal begins to deteriorate.

Dr. Woodhead, in his evidence before the Royal Commission on Tuberculosis, declares the temperature in the centre of a cooked joint of over 6 lb. in weight seldom reaches 60 deg. Cent., and goes on to say:—"Ordinary cooking, such as boiling, or more especially roasting, though quite sufficient to sterilise the surface and even the substance for a short distance from the surface of the joint, cannot be relied upon to sterilise tubercular material (and caseous matter) included in the centre of rolls of meat, especially when these are more than 3 lb. or 4 lb. in weight. The least reliable method of cooking for this purpose is roasting before the fire; next comes roasting in an oven, and then boiling."

Now, it comes to this, by way of illustration:—Given a leg of mutton or a round of beef rather undercooked with a caseous gland embedded somewhat deeply in the same, what amount of risk of infection is run in eating the flesh? Again, what risk is run when a medical man orders a child or adult raw—or nearly raw—meat juice, and such material is derived from a tuberculous animal? I can only answer that there is a very appreciable risk, and that this has been proved by direct experiment on the lower animals. Kastner obtained positive results by the injection into animals of the juice of confiscated flesh of tuberculous animals; and Steinheil succeeded in transmitting tubercu

* *Quarterly Medical Journal.*

losis to guinea pigs by administering the expressed juice from flesh in which no tubercle could be seen.

That milk is a source of grave risk cannot be disputed.

The practical question, then, that we have to answer is this:—Is there an actual risk of infection through the ingestion of uncooked, or partially cooked, flesh or milk of tuberculous animals. The answer is undoubtedly in the affirmative.

The Jews are much more exempt from tubercle than any other race, and there is little doubt that much of this exemption is due to the great care exercised in the choice and dressing of their meat. The following two facts are worthy of note:—In Copenhagen slaughter-houses, in 1890 to 1893 inclusive, the percentage of tuberculous animals was 17·7 for oxen and cows, 15·3 for swine, 0·2 for calves, and 0·0003 for sheep; in the Berlin slaughter-houses in 1892—3 the percentage was 15·1 for oxen and cows, 1·55 for swine, 0·11 for calves, and 0·004 for sheep; in Edinburgh of 300 milch cows slaughtered in 1890 no less than 40 per cent. (varying from 12 to 83 in one cowhouse or another) were found to be tubercular. In 1895 there were in England 7389 deaths from tabes mesenterica, of which 3855 were under the age of one year; 6746 from tubercular meningitis; 42,490 from phthisis; and 6084 from other forms of tubercle; making a total of 62,709. Without adding marasmus, bronchitis, diarrhœa, and pneumonia—some of which are undoubtedly tubercular—this is a tremendous total, almost the whole of which can be laid down to tubercle.

Having answered—as I am certainly justified in doing—the question respecting the actual risk of eating tuberculous meat and drinking tuberculous milk in the affirmative, what a grave responsibility rests with the public Authorities in dealing with the traffic in diseased or possibly diseased animals. What new importance attaches to the due administration of the Dairies and Cowsheds Orders and to the question of the establishment of public abattoirs?

(To be continued.)

INFECTED MILK AND CREAM FROM ABROAD.

One of the last acts of the late Commissioners of Sewers of the City of London was to institute an inquiry into the conditions under which milk and cream are imported into this country from abroad. From their report, a copy of which has reached us, it appears that in 1894 161,633 gallons, and during the eleven months of November, 1895, 124,915 gallons of milk and cream were imported into the United Kingdom from Sweden, Holland, Belgium, Norway, Denmark, and North Russia. Of the latter quantity Sweden contributed 109,428 gallons and Holland 14,103 gallons; of the balance—1384 gallons—one-half was imported from Norway, whilst the remainder came from Belgium, Denmark, and North Russia. The committee made it their business, through the Foreign-office, to obtain copies of the regulations in force in these countries for the prevention of the sale of possibly infected milk, and the despatches subsequently received from the English Consuls have been compiled and printed in *brochure* form. In Belgium, the necessity for the special inspection of dairy farms is universally recognised, and the Belgian Government are considering the organisation of this service, but at present no regulations appear to have been publicly issued upon the subject. In the Royal decrees applying to the rule of milk there is no reference made to milk sent out of the country. In Sweden there are no regulations in force under which cattle are reared and kept, this being left entirely to the means and judgment of the agriculturist, nor are there any regulations providing for the inspection of milk and cream intended for export. With regard to the small quantity of milk exported from Finland no regulations are in force for ensuring the purity of this supply. In Holland a recent decree has been published which contains all the regulations enforced by the Government with the view to ensuring the purity of the milk supply. In Denmark care appears to be enforced in dealing with infected animals, but we find no marked reference to milk sent out of the country. The document is one which deserves the serious attention of the Government.

FOOD AND THE STATE OF HEALTH.

In selecting food in reference to health, says *Health*, it must be remembered that there are certain general rules which have been established by the best authorities through many ages and in a great variety of circumstances; there are, however, some exceptions to these general rules. Milk is considered a wholesome food, yet there are some persons who cannot take it. Cheese is a cheap and nourishing food for labouring people, but there are some persons to whom it is an active poison. This is also the case of oysters and strawberries. These exceptions are owing to some idiosyncrasy of the palate or weakness of the digestive organs, and should be regarded only as exceptions, which do not affect the general principle.

In cases of sickness, after long-continued, prostrating, or rapidly-wasting disease, the system demands immediate nourishment to supply that waste, or when there is a lack of nutriment from any cause. Food that contains the most nourishment in the most easily assimilated form is now needed; but the physician should always be consulted as to the food suitable during different diseases. Liquid food is most suitable, and should be food as well as drink. In nearly all cases of fever, milk is given when the patient can take it. Two or three grains of pepsin in a cup of milk or broth facilitate its digestion. In cases of typhoid fevers milk has often proved of great value, and is now generally recommended by the medical faculty in all cases of scarlet fever, nervous disorder, and all diseases arising from imperfect nutrition. It keeps up the strength of the patient, acts well upon the stomach, soothes the intestines, and promotes sleep. Meat broth, farina, and oatmeal gruel are also suitable at such times; but beef tea and beef juice are most generally used by physicians. They afford a fluid and easily-assimilated form of food, and have a remarkable power of restoring the vigorous action of the heart and dissipating the sense of exhaustion following severe prolonged exertions.

A SANITARY SAUSAGE FACTORY.

Not one in a thousand in this *fin de siècle* age would dream of finding a sausage factory within the precincts of an Essex dairy-farm. In fact, we were eagerly bent on keeping milk and preserving cream not made into butter. The scene we beheld on reaching Leytonstone, the birthplace of the redoubtable Sir Morell Mackenzie, who attended the late Emperor Frederick of Prussia, was truly rural. But we had missed our port. Hainault-road, which is not in Epping Forest, was our destination, and to our dismay we found it was situated in Abbott's Park, close by Leyton Station. Therefore we trudged back to the old Roman station of Durolitum, the birthplace of Sir Thomas Rowe, an Oriental traveller; and in the church there is a memorial of Sir Josiah Child, the founder of the famous Child's Bank.

Abbott's Park is close to the Midland line, and in two large fields were several colts scampering over the green turf in the ruddy glow of the November sun; and there appeared on the wall in bold letters the well-known legend—

ABBOTT BROS., Estab. 1786. { Branches— Leytonstone, Woodford, Forest Gate, Limehouse, Southend, Gravesend.

As we passed along the Hainault-road, we paused, like the school folks, to look into the cowshed, which has a large plate-glass window fronting the road, and here nursemaids and their youthful charges do congregate to watch the milkers at work, and the gambols of the tiny calves on the straw near the opening. The retail dairy next comes in sight, and we enter therein to be cordially welcomed by the genial manager, Mr. Walter Burton, whom we recognised as a "high-flyer"—an enthusiastic breeder of homing pigeons. We foregathered at once; and, after tales of tiger and elephant hunting, we were taken over the dairy-farm of Messrs. Abbott Brothers, of Gun-lane, Limehouse, which is their head office. The shop, which is attached to the manager's house, is very neatly arranged, and the decorations comprised the heads of well-tined deer, with the antlers and tusks of formidable wild beasts well known in the Indian jungle, which is familiar to Mr. Burton. On the right is the cowhouse, containing stalls for a number of cows and heifers in milk, fitted up in a manner calculated to receive the approval of the Sanitary Inspector of the County Council. In all we saw the building was in every way well adapted for the supply of pure milk to trustful and appreciative customers. Delicate babies are fed on milk from special cows, and the general public are assured that the milk is purveyed as "the cows give it." The washing-up room is close by, with a hot-water tank to enable the men to swill out the cans and churns; while the steam jet arrangement and drying rooms are contiguous. Overhead is the loft or granary, where corn, hay, straw, and chaff are stored for the live stock of the farm.

The horses required on the rounds are stabled in stalls at the end of the building containing the cows and heifers, while others are accommodated elsewhere in the yard. Next door is the coach-house, which is very commodious. In line with the coach-room is a range of thirty pig-styes, containing on an average about ten each. The houses are composed of wooden sides, asphalted roofs, with floor or platform for resting covered with straw and sawdust, and outside the floor is of cement, with a fall to the gutter. The breeds are pure Berkshires, Yorkshires, and Tamworths, and crosses from these strains. Messrs. Abbott Brothers breed and feed for exhibition, and they also utilise the cross-bred pork for toothsome joints, sausages, and brawn.

Immediately in front of the piggeries is a wooden house, covered with glass, evidently used originally for feathered stock, but now relegated to stores. From the centre of it rises a house for pigeons, which abound in the yard. A mixing trough is placed nearly in the middle of the yard, and here the feeder prepares the mash for the pigs. Necessarily, the yard is fairly wide and open, to admit of the ingress and egress of the numerous floats which rush out and in carrying the stores of this Essex Dairy Farm. The range of buildings on the left hand are devoted to the feathered world, and here fowl, goose, duck, and pigeon find a roosting-place, while some prefer the trees. The duck pond is a fair size for the flock of Chinese geese, Rouen ducks, Indian runners, &c. In front of the pond is a Swiss châlet, which once belonged to a famous licensed house in the neighbourhood, but it now holds the baskets, bags, and boxes required for the produce of the farm.

And now we have almost made a round of the premises. We enter a covered shelter, in which a pony trap can stand and be protected from the elements. Then the engine-room is reached, in which is fitted one of Mr. E. Hindley's (Bourton and London) vertical engines, which drives the separator and the sausage machine next door. This factory is quite a new erection, and was recently opened. It is a building 30ft. long, 16ft. wide, and about 20ft. high. Outside it is of glazed bricks, with overhanging eaves, tiled roof, and ventilating ridge. The natural light is obtained from plate glass windows—plate glass in the Hainault-road frontage and stained at other end—with four small windows on the sides, with revolving sashes to permit a free draught of air. Within, the factory is well appointed, and artificially illuminated with incandescent (Welsbach) light.

The floor is concrete, the walls are of white glazed brick, the roof is boarded inside and painted, being supported on iron spandrels and braced firmly together. There is a sausage machine which is worked by steam power, and an excellent supply of pure water direct from the main. In the window is a slab for displaying the finished article; and those connoisseurs of pork can see the manipulators busily at work, and select their own cut. The meat is thoroughly washed and prepared by practical men on spotlessly clean wooden slabs, or cutting tables; and the butcher's block is also an indication of the sanitary arrangements in this suburban factory. It has all the appearance of a first-class pork-butcher's shop, as there are rails with hooks on which to hang the meat to dry for use. We saw one porker—a cross between a Berkshire and Yorkshire — weighing 46 stone, which had been fattened in the yard and killed by a professional butcher on his licensed premises. About nine pigs per week are usually made into pork; and over 1000 lb. of sausages go out during the same period. With the facilities

at hand, this quantity can easily be trebled or even quadrupled. The pigs, bred and fattened, generally number 1000 per year, and there are seldom less than 300 on hand at one time. Hence "the gintleman that pays the rint" in "Ould Ireland" is likely to turn a purely local enterprise into a far-reaching and ever-spreading business. The piquancy and flavour of the Abbott Park sausages have spread their fame far and wide; and the daily increasing business augurs well for its future development.

There is a very large flock of poultry and ducks kept, chiefly for eggs, which are in great demand in all the branches. The fowls are cross-bred, such as Indian Game—Dorking, which are so good for table; and also Langshans, Plymouth Rocks, Minorcas, and Leghorns. The whole flock numbers over 300 head, and they are as free to go over lea and meadow as the air we breathe. Commodious roosting houses have been erected for their comfort, and feeding troughs are placed in convenient positions in the spacious yards. The peacock and his mates are the pride of the lot, although the plumage of many of the ducks is exceedingly beautiful. But when either of them open their mouths they exhibit the decadence of the race and sustain the reputation of unmusical 'Arrys and 'Arriets of the feathered tribe. But why that commotion? The peacock screams, his mates screech, the pigeons hie to their cots, and the fowls fly and flutter. Rose (the fox terrier) was on the trail of a rat, which she triumphantly dispatched before it could reach its lair, to the evident satisfaction of every member of the feathered world in Abbott's Park.

A DANISH MILK SUPPLY COMPANY.

By Dr. T. G. Nasmyth, M.O.H., Fifeshire.

The operations of the Copenhagen Milk Supply Company have attracted more attention than any other milk business in the world, and their system has become one for imitation. It would be impossible at this time to give more than a summary of the details of their system. First, as to the cows. The company endeavours to secure cows free from tubercular diseases, as indicated by the tuberculin test. The feeding of the cows is most carefully superintended, and the health of the cows is watched over by a staff of veterinary inspectors connected with the company. The occurrence of infectious disease is guarded against by the contract between the farmers and the company, in virtue of which the milk is at once withdrawn on the occurrence of infectious disease amongst any of the workpeople. The milk all the same is paid for all the time it is withdrawn. The company's factory covers an area of two acres of ground in a suburb of Copenhagen, conveniently situated for trains arriving from different parts of Zeeland. The milk is obtained from fifty-seven large farms and over 5000 cows, the farms being at considerable distances from the city. There is but one delivery of milk a day at the factory, which is in the evening. This consists of the top cream, second-class cream, half-skimmed milk, ordinary new milk, and children's milk.

The different milks are brought in cans of different shapes and sizes so as to avoid mistakes. When the railway truck arrives at the factory the temperature is noted, and must not exceed 50 deg. Fah. Across the truck are stretched two box compartments containing ice, so as to keep the temperature of the air in the truck, and therefore the temperature of the milk, down to the required point. They are immediately taken into a reception-room in the factory, when it is at once seen that they were fastened and sealed in such a way as to prohibit tampering with the milk on the way. The cans are opened and a small portion tasted by one of the employés, while the temperature is rapidly taken. If any taste was found in the milk, it would be rejected. The half-skimmed milk and new milks were then put in ice-water tanks, while operations at once commence on the cream and children's milk. These, or at least the latter, are at once filtered through gravel filters into a large bowl, the filters being in the cool room. There is but little work going on in this room. The milk after filtration runs along a pipe, which perforates the wall separating this room from the bottling room, which pipe is connected with six taps. From these taps the bottles are filled—one person presiding over the taps, who hands the bottle to a second, by whom the milk is adjusted to a mark on the bottle. A third corks the bottle by an ingenious machine, which leaves the cork just at the proper level on the top of the bottle, which is notched. The cork is then tied down with a string, and the string is sealed. As rapidly as they are completed the bottles are placed in crates and ice placed on them. When this operation is completed, the new milk and half-skimmed milks are similarly filtered and afterwards run into cans. These operations occupy the night shift till it is time to load and send out the morning vans, which carry the milk and creams to the houses and to the company's shops. The greater part of the business is house supply. Every precaution which ingenuity can suggest is taken to prevent fraud. The drivers cannot get at the cans, from which the milk is run off by taps projecting from the van. The operations of cleansing the cans, bottles, &c., commence as soon as the milk is sent off in the morning. The filters are sterilised and thoroughly cleaned every day. The bottles are washed with soda and hot water and scrubbed out with a brush. They are then rinsed with clean, cold water, and put on racks upside down to dry. The farmers' cans and the company's cans are subjected to a rigorous process of cleansing with limewater, hot water, and sterilising by means of steam. They are also put upside down on racks to dry. The workpeople are clad in clean overalls. The premises are most spacious. The floor of the establishment is of a specially excellent asphalt composition. The walls and roof are scrupulously clean. Care is taken that the milkers should have clean hands. The cows, especially the udders, are scrupulously clean. The morning's milk is taken at once to the dairy, where it is poured into long narrow vessels about 3ft. deep, which stand in tanks containing ice and water. When it has stood for about ten hours the cream is withdrawn in two qualities and put into two distinct cans, the milk left (half skimmed milk) being also placed in distinct cans. The afternoon's milk is at once cooled down in the dairy by flowing over a Lawrence cooler, through which circulates a mixture of ice and water. This second supply is the new milk, and is put into

separate cans according as it is ordinary, new milk, or children's milk.

Such is a brief account of the Copenhagen Milk Supply Company. In this country, while we have nothing to compare with it either for extent or completeness, there are various dairy companies imitating the Copenhagen one. Various places now go in for selling sterilised milk, samples of which are shown. When milk is thoroughly sterilised all risks of scarlet fever, enteric, diphtheria, or tubercular diseases are discounted, so that its use is decidedly to be recommended.

THE NEED OF FAT FOODS.

The idea that fat is necessarily unwholesome is a mischievous one. The proper nourishment of the body requires a certain proportion of fat. The only objection we urge against fats as foods is the manner in which they are taken. In the form of rich cakes, pastry, fried food, melted fats, as used with salads, butter on hot bread or potatoes, and the like, fats are difficult of digestion, and often interfere with the digestion of other foods. Animal fats are, at least in a free state, much less digestible than vegetable fats. Cooking renders most elements of the food more digestible; or, rather, cooking is a sort of partial digestion of most food elements.

Fats are, however, an exception to this rule. Cooking greatly increases the indigestibility of fats, which at best are hard to digest in a free state. The most acceptable form in which fats can be introduced into the body is in cream, in grains like corn or oatmeal, in such nuts as almonds and chestnuts, and in the legumes, as peas, beans, and lentils. When taken in this form fats are easily digested, and, when assimilated, serve to build up the brain and nerves and encourage the nutrition of other tissues. Butter is not an economical fat. The process of digesting butter is essentially a process of unchurning. The housewife, then, wastes her labour in churning the cream, and the butter eater his in unchurning it. Besides, butter is rarely found in a perfectly sweet condition. As ordinarily made, butter will not keep longer than milk, unless kept on ice. Tainted butter is a most unwholesome article. It sets up a process of decay and fermentation in the stomach, and is wholly unfit to enter a human stomach. The same must be said of cheese. The latter article, if eaten at all, should invariably be first cooked. Heat destroys the germs present in cheese, and decomposes the poisonous compounds which it contains.

MEAT INSPECTION ON THE CONTINENT.

It is well known that sanitary legislation, especially in regard to foodstuffs, is more advanced in many continental countries than it is here.

In Belgium, one of the nearest and most enlightened, a complete system of meat inspection was instituted in 1890. One of the regulations states—"1. The Government is authorised to regulate and supervise the trade in foodstuffs, and substances used for the food of man and animals, but only from the point of view of public health, or with the object of preventing imposture and adulteration.

"It can further, but only in the interests of public health— . . . . As regards butcher's meat especially, it must not be exposed for sale or sold unless it has been recognised as fit for food after an expert examination. If fresh meat is in question, this expert examination must take account of the condition of the internal organs."

Regulations are also made, and definite instructions given regarding the inspection of meat imported from abroad.

Most of the continental countries proceed on somewhat similar lines with different variations, and surely we ought not to be behind in protecting the public so far as possible from being imposed on with unwholesome or diseased meat. In Prussia the regulation states—"All animals must be examined before and after slaughter by a veterinary surgeon, or by an Inspector. The latter, however, can only pass judgment in certain definite conditions (which are elsewhere specified), and must call in a veterinary surgeon whenever there is the least doubt." "No animal may be slaughtered or cut up without the approval of the Inspector, and only such parts of the carcase may be used for food as are passed by him. In the case of fresh meat introduced from without, a certificate must accompany it, showing that it has been inspected by an expert." And in Norway—"In every commune where the above laws are in force, all fresh meat exposed for sale for human consumption must be examined by the Municipal Inspector and stamped." The laws referred to are in connection with the establishment of public slaughter-houses.

Imitation Worcester Sauce.—The time is coming when we shall have to examine the labels of our sauce-bottles as carefully as those of our wine. A German at Meiningen is advertising for the recipe of "genuine Worcestershire sauce." Now, Germany is the generous country which sends us "genuine eau de Cologne" in large bottles for 2d., as may be seen in Mr. Chamberlain's museum of Yankee notions and German shoddy; and when the patriotic British grocer offers us Worcestershire sauce at 1½d. a quart, we may begin to smell a German rat. Perhaps when the bottle is uncorked we might do so in reality, for dead rats would be as cheap an ingredient as any other.

DR TIBBLES' Vi-Cocoa

THE WONDERFUL FOOD BEVERAGE.

A Food Beverage such as Dr. Tibbles' Vi-Cocoa, with its unique powers of nutriment and exceptional vitalising properties, is a means whereby strength and nervous energy is gained as a rational outcome of increased vitality.

It has the refreshing properties of fine tea, the nourishment of the best cocoas, and a tonic and recuperative force possessed by neither, and can be used in all cases where tea and coffee are prohibited.

Dr. Tibbles' Vi-Cocoa, 6d., 9d., and 1s. 6d., can be obtained from grocers, chemists, and stores, or from Dr. Tibbles' Vi-Cocoa, Limited, 60, 61, and 62, Bunhill Row, London, E.C.

Food and Health

SUPPLEMENT TO

THE SANITARY RECORD.

No. 13. FEBRUARY, 1898.

A GREAT PUBLIC BOON

LIPTON

Has commenced making Extract of Beef and Fluid Beef, and is now offering to the Public the

FINEST QUALITY

EXTRACT OF BEEF

AND

FLUID BEEF,

At prices which will place these most valuable articles of food **WITHIN THE REACH OF ALL.**

LIPTON'S EXTRACT of BEEF and LIPTON'S FLUID BEEF SAVE PURCHASERS 25 to 35 PER CENT.

LIPTON'S EXTRACT of BEEF and FLUID BEEF are made from the finest quality of Fresh Ox Beef, under the most skilful, scientific, and practical supervision, by a process entirely his own, and contain all its nourishing, stimulating, and strengthening properties. They are invaluable alike to the invalid and the strong. They nourish and fortify the system, and are unequalled for their strength-giving properties.

THE DAYS OF HUGE PROFITS ARE OVER!

It is admitted by everyone that LIPTON caused a revolution in the TEA TRADE, and forced Tea Dealers and Merchants to REDUCE THEIR PRICES. Before LIPTON introduced his celebrated TEAS the PUBLIC HAD TO PAY nearly double the price they are now charged by LIPTON for the Finest Teas the World can produce.

WHAT LIPTON HAS DONE IN THE TEA TRADE, LIPTON WILL DO IN THE EXTRACT OF BEEF TRADE.

LIPTON'S EXTRACT of BEEF or FLUID BEEF makes the richest Beef Tea. They are also invaluable in the domestic economy, and will be found by all good cooks the most economical and the best for flavouring soups, gravies, sauces, entrées, &c.

LIPTON'S FLUID BEEF has the three principal properties of meat, viz.: ALBUMEN, FIBRINE, and ESSENCE of BEEF in equal proportions, thus making A PERFECT BEEF FOOD; and as there are no condiments nor preservatives of a foreign nature used, it will be found that the NATURAL FLAVOUR OF THE BEEF IS RETAINED.

LIPTON'S EXTRACT OF BEEF & LIPTON'S FLUID BEEF.

UPON THE PUBLIC VERDICT LIPTON will rely. One trial of his Extract of Beef and Fluid Beef, he is confident, will ensure their being used in future in every home.

Lipton's Extract of Beef and Fluid Beef can be obtained at Lipton's Markets and Agencies throughout the World.

Samples sent to Medical Officers of Health on application to

Lipton's Chief Offices: **CITY ROAD, LONDON, E. C**

FOODSTUFFS UNDER SCRUTINY.

WHAT TO EAT AND DRINK, AND WHAT TO AVOID.

"SANITARY RECORD" ANALYSES.

IMPORTANT ANNOUNCEMENT.

Owing to the growing popularity of this feature of our "Food and Health" Supplement, we have found it necessary to make arrangements whereby, in future, much fuller reports will be given of proprietary articles than have appeared hitherto. It has been our custom to solicit samples of articles for investigation from the manufacturers direct, unconditionally; but in future such samples as we receive from the proprietors thereof will require to be accompanied by a declaration that the sample is selected from stock, and not put up for the special purpose of analysis. Failing this we shall make the purchases ourselves, selecting the articles at random from the various retail establishments where they are sold.

We have retained the services of Mr. C. G. Moor, M.A., to examine and report on the various substances submitted to us.

All such analyses may of course be quoted as having appeared in The Sanitary Record, but the date must be given, and Mr. Moor's name must not be quoted for advertising purposes without special permission.

"Oxine."

"Oxine" Limited, Wholesale Depot, 29, Walbrook-street, E.C.

I have examined the sample of "Oxine" (in jelly form) with the following results:—

Moisture	42·0	per cent.
Mineral Water	7·5	,,
Albuminoids	42·0	,,
Carbohydrates, &c. ...	8·5	,,
	100·0	

The mineral matter contained ·86 per cent. of phosphoric acid (P_2O_5), calculated on the original sample.

Microscopic examination of "Oxine" showed the presence of muscular fibres of meat and vegetable structures.

This preparation is sold in two forms, the jelly being put up in vacuum jars, and in tablets. In the latter form its extreme portability should recommend it to all travellers, while the jelly form sold in jars is also highly concentrated, seeing that it contains 58 per cent. of solid matter.

The preparation is quite free from poisonous metals, and very palatable. It is a novel and very valuable one, possessing features that distinguish it from the host of meat extracts and fluids that are offered to the public.

DISEASED AND UNWHOLESOME MEAT.*

By T. Robinson.

Continued from January.

Bad meat may owe its unwholesome quality to a variety of causes, and may in various ways answer to the description set forth at the beginning of this article.

"Discoloured" or "stained" flesh may be met with in any part or organ of the body, such as the heart, lymphatics, liver, muscles, pleura, peritoneum, &c., and is due to such diseases as advanced pleuro-pneumonia, septic, inflammatory (*e.g.*, parturient) fever, swine fever, erysipelas, &c. On cutting through a muscle of a recently killed—previously supposed to be healthy—animal, it is not uncommon to see it of various hues of red, from pale to dark, showing most distinctly that changes have already taken place in such muscle. Then, again, the heart and endocardium, or kidney, may be distinctly blood-stained to some depth into their tissue. This is positive evidence of the animal having suffered from a septic disease, such as swine fever.

"Unbled"—or only partially bled—meat, as I have already said, is of a dark-red colour, sticky and soft to the touch, does not set well, and yields a thickish, sticky, and dark juice. This is the condition of things one would expect to find in animals that have died, or been drowned, or suffocated.

"Unbled," "stained," or "discoloured" meat, therefore, is all to be condemned, whether it is fat, lean, or fairly nourished; and why? Although such diseases as pleuro-pneumonia, septic, inflammatory, parturient, or swine fever, may not be directly communicable to man, yet these fevers undoubtedly bring about such changes in the flesh as to render it a suitable medium for the growth of bacilli or the formation of ptomaines, and under such conditions this meat might become highly poisonous in the short space of a few hours.

"Unbled" meat is often that of a diseased animal that has died before the butcher has had time to "finish it off;" in such a case, it is possible the disease may be one readily communicable to man. But any "unbled" meat soon decomposes, and, in addition, is one of the best media for the growth of bacilli, either pathogenic or non-pathogenic. The peculiar, and frequently evil, odour of such flesh is best observed on a skewer that has been plunged deeply into its substance.

Pork, without any observable deleterious qualities, acts on many people almost like a poison. This may be due to the more rapid decomposition of pig-flesh, and hence the early formation of ptomaines, or the growth of a special pathogenic bacillus, as described by Klein in the Welbeck Disease, in 1880. It is therefore essential that pig flesh should be more carefully watched than any other kind of meat.

At Welbeck, in 1880, seventy-two persons were extremely ill, and four died, after eating some boiled ham. At Middleburgh, Holland, in 1887, 256 soldiers and thirty-six citizens were taken ill after eating meat from a cow killed whilst suffering from puerperal fever. Gärtner records a large number of cases of persons who were poisoned by

* *Quarterly Medical Journal.*

eating the flesh of a cow that had suffered for two days from diarrhœa. The symptoms of ptomaine poisoning are well known; briefly, they are—gastro-intestinal irritation, nausea, vomiting, pain in epigastrium, and diarrhœa, which may be almost choleraic, followed by collapse, and often death.

"Emaciated" meat, from whatever cause, either disease or old age, is innutritious, and therefore not of the "nature and quality demanded by the purchaser." Such meat should certainly be condemned, and it should be remembered by the public that there is always danger of poisoning in eating such meat, however well cooked or "seasoned" it may be.

The chief symptoms of swine fever (also called "hog cholera," "typhoid of swine," "purples," &c.) are diarrhœa and broncho-pneumonia, with extravasation of blood on the skin, chiefly behind the ears, on the limbs, on the under-surface of the abdomen, and some few on the back; after death these extravasations are found to extend down through the skin and subcutaneous tissue to the muscle. Extravasations are also found in the lymphatics (lumbar chiefly), heart, and kidneys, and also sometimes in the muscles. As the case advances the bowels ulcerate. Up to the present time swine fever has not been known to affect human beings, and so in the very early stages it is advocated that the meat should be passed as fit for food. The flesh of pigs that have suffered for some time is pale, wet, flaccid, and has a peculiar odour. This must unquestionably be condemned. In the more advanced cases the blood often undergoes a change in colour, to a darker tint, and may become almost "tarry." This would naturally give the meat a darker, or even a purple hue. Owing to the compulsory notification of swine fever to the Board of Agriculture, most of the carcases of swine-fever pigs are confiscated, but in spite of all precautions many find their way into the "slink" markets, and thence in all probability into the sausage machine.

It would be as well, perhaps, before leaving this subject, just to mention that the superficial burning of pig's skin by lime in cattle trucks and the so-called "diamonds" must not be mistaken for the extravasation of swine fever. Careful examination by the professional eye will distinguish the burn in its early stages, and in the case of "diamonds" the history—of very sudden and general appearance—of the comparatively good health of the animal, and the character of the patches, of varying colour and for the most part diamond-shaped, will generally be sufficient evidence on which to form a diagnosis. Of the exact nature of the disease "diamonds" very little is known, except that it is due to a blood change, and the flesh must be judged on its merits.

Parasitic diseases also must be considered.

Liver fluke (*Distoma hepaticum*), commonly known as "rot in sheep," is shaped like a fluke fish, from whence, no doubt, it gets its name, and measures from 1in. to 1½in. in length, about half its length in breadth, and from $\frac{1}{16}$in. to $\frac{1}{8}$in. in thickness. It inhabits the bile-ducts, is commonest in sheep, but is also found in oxen. It causes blocking in the bile-ducts, destruction of the liver substance, and wasting of the liver, diarrhœa, jaundice, falling off of the hair, and general dropsy and emaciation. The flesh has to be judged on its merits, but the liver must most certainly be condemned. The Scotch shepherds eat flukey liver, and say it does them no harm; unfortunately, there are not enough necropsies of these brave shepherds to confirm or refute their statements.

Measles in pork (*Tænia solium*) is due to the cysticercus cellulosæ being disseminated in the liver, muscles, connective tissue, brain, &c., but not in the fat. The cysts are on an average the size of a pea, and are noticeable during life beneath and on the sides of the tongue. Hooklets can be obtained from the cysts; and some cysts may have undergone calcareous degeneration. All measly meat must be condemned, as this cysticercus is one of the two phases in the life of the *tænia solium*, which latter is developed from it in man.

Trichina spiralis is a nematode that affects the muscles of pigs and other animals in the form of an ovoid cyst just visible to the naked eye. Its demonstration is made easier if a small portion of the muscle is first treated with liquor potassi, for the cyst then becomes more distinct, and the worm more easily seen with a magnifying glass. The miniature worm is coiled up in the cyst, and is about one-thirtieth inch long. This disease is transmissible to man, and all meat affected by it must be condemned.

Strongylus filaria is a nematode found in the lungs of sheep and lambs, but is not a common affection in England. It is a slender worm, reddish-brown in colour, and about an inch long. It causes during life much bronchial irritation and a husky cough. The lungs (*post mortem*) show numerous small nodules throughout their substance, yellow in colour, about the size of a pin's head—some hard and almost calcareous, others softer, and others again surrounded by a small quantity of thin pus. The worm is easily demonstrated under the microscope after squeezing one of these nodules on a cover-glass. This parasite is not known to affect any other organ than the lungs, and has not been found in man, so that the lungs must be condemned and the meat judged on its merits. The lungs of a sheep recently seized and condemned by the Health Department in Nottingham, on account of extreme malnutrition, were found to be thickly studded in all parts with this nematode.

Anthrax and actinomycosis are the only two other diseases I shall mention.

Malignant pustule, splenic apoplexy, or splenic fever was the cause of thirteen deaths of human beings in England during 1895—eleven males between the ages of ten and sixty-five, and two females between the ages of fifteen and forty-five. This disease is uncommon, but at the same time rapidly fatal in all animals. The chief signs are: enlargement and congestion of the liver, spleen, kidneys, and lymphatics; the spleen is especially large, soft, and dark. Extravasations of blood are not infrequent.

The bacillus of anthrax being pathogenic, and the spores very hard to destroy, it is absolutely essential that the flesh of animals suffering from this disease should be destroyed by fire.

Ray-fungus, or actinomycosis, although not very common in England, is found in Norfolk and other parts; it is also known by the names of "wooden tongue," "lumpy jaw," and chiefly affects oxen. It is generally found about the head and neck of the animal, and, in most cases, one side of the

tongue and one ramus of the jaw are affected, hence its name. This fungus is pathogenic, and the spores are very resistant to heat, requiring according to Wurtz, fourteen minutes' boiling to destroy safely.

There is no separate return of deaths from this disease by the Registrar-General, but I am of the opinion that it is of much more frequent occurrence than is generally supposed. It is desirable that every medical man should examine carefully the pus of any abscess he cannot otherwise explain, for granules about the size of a millet seed and of a canary colour—those of the ray-fungus.

In conclusion, I can only hope that these imperfect notes may interest some few who are interested in the subject, but have not much time to devote to its study; and I have to thank Dr. Boobbyer, of Nottingham, for the many facilities given me for inspecting condemned meat in that town.

HORSE FLESH AS FOOD.

The prejudice against horse flesh as food is one that time and experience are fast dissipating. In France and other continental countries the use of this aliment is increasing so rapidly that great attention is given to the fattening of horses for the market. It is conceded that the flesh of these animals is most excellent and nourishing. Liebig, Mohschott, and other chemists have demonstrated that the muscles of horses contain a greater percentage of albumen than those of oxen and cows. Smoked horse tongues are acknowledged to be more delicate than those of the now extinct buffalo.

Horse tea is recommended to invalids as possessing greater tonic potency than beef tea. It is more savoury and nourishing. The broth is of the colour of chicken bouillon. As soup stock it has the taste of that made from game, and the same quantity of solid produces a larger quantity of liquid. Hippic meat requires a longer time to cook. When boiled it is apt to crumble; when roasted it is said to suggest venison. There is no part of the horse that cannot be utilised. Inferior portions may be employed in ragouts, whose flavour is much more piquant than when made from corresponding cuts of beef or mutton. The colour of the meat when roasted or boiled is darker than that of the ox. As the grain is shorter and more brittle greater skill is required in the carving. The decreasing use of horses as beasts of burden, through the employment of mechanical modes of propulsion, suggests the value of considering them seriously as an article of food. Every year there is more or less of a panic in regard to the short supply of beef. The horse, accorded the same care in selection and preparation for market, offers an entirely satisfactory substitute. Margarine has kept the price of butter within reasonable limits. Would not a general use of hippic meat be an equally effective check upon the cost of beef? The pot-au-feu, which is no longer boiled in thousands of French homes, on account of the cost of beef, through the cheapness of hippic tissue, has assumed its former importance in the domestic economy of that people.

DANGEROUS MILK SUPPLIES.

In the course of his annual report Dr. Karkeek, Medical Officer of Health, Torquay, remarks:—"In my annual report for 1894 I drew attention to the urgent necessity for townspeople being empowered to exercise supervision over the farms, &c., which supply them with milk; in other words, that the consumer should have control over the producer and distributor. Year by year my experience tends to convince me of the importance of this question. During the past year the following facts corroborate this view. An epidemic of scarlatina was in full swing in a village whence large quantities of milk, &c., were sent to Torquay. Fortunately there were on the spot some very intelligent farmers who had large financial interest in the milk business, and they carried out all my suggestions, and saw to the exclusion of the labourers living in infected houses from attending to the cows or milk. But things might have been very different with a different result. In another case I ascertained that on a farm some miles from Torquay there was scarlatina, and that the dairy produce of the farm was sent to Torquay. I at once proceeded to the farm, and found the sick child seated in the living-room common to the whole family. The farmer's wife nursed the child and attended to the dairy, and this part of the house was separated by a door from the living-room, which was constantly being used. There was no attempt at isolation, and consequently it was imperative that such a contaminated supply should be stopped. This was done in respect of Torquay; but I have not the least doubt that it was sent elsewhere. . . . My impression is that towns should have power to ascertain from milk purveyors whence their supplies are brought; that each farm should be inspected and licensed; and that notification of all infectious diseases should be sent to the Sanitary Authority of the districts where the dairy produce is consumed."

SALE OF FOODS AND DRUGS BILL, 1897.

The Council of the Society of Public Analysts, reporting on the Bill of last session, arrived at the following conclusions:—

"That the Draft Bill introduced by the President and Secretary of the Local Government Board is unsatisfactory, inasmuch as it does not embody the most important recommendations of the Food Products Adulteration Committee, and that, if passed, it would not lead to the removal of the difficulties experienced in carrying out the present Sale of Foods and Drugs Acts.

"That the recommendation of the Food Products Adulteration Committee, subject to but few modifications, should be embodied in any Bill which may be put before Parliament during the coming session.

"That the most important recommendation of the Select Committee, viz., recommendation No. 19, referring to the formation of a Court of Reference, constituted substantially as laid down in the body of the report (with, however, the inclusion in its number of one or more public analysts) should be acted upon, if new legislation is to lead to satisfactory results."

BREAD THE WORLD OVER

VARIOUS FORMS OF THE STAFF OF LIFE IN DIFFERENT COUNTRIES OF THE EARTH.

It is a curious and interesting study to compare the various materials which serve the different nations of the world as the basis of their bread. In this country, where good bread, made from spring and fall wheat flour, is within the reach of all, rarely a thought is given to the fact that, after all, the inhabitants of only a small portion of the earth's surface enjoy such a food.

In the remoter parts of Sweden the poor people make and bake their rye bread twice a year, and store the loaves away, so that eventually they are as hard as bricks. Further north still bread is made from barley and oats. In Lapland, oats, with the inner bark of the pine, are used. The two together, well ground and mixed, are made into large flat cakes, cooked in a pan over the fire. In dreary Kamchatka, pine or birch bark by itself, well macerated, pounded and baked, frequently constitutes the whole of the native bread food. The Icelander scrapes the "Iceland moss" off the rocks and grinds it into fine flour, which serves both for bread and puddings. In some parts of Siberia, China, and other Eastern countries, a fairly palatable bread is made from buckwheat. In parts of Italy chestnuts are cooked, ground into meal and used for making bread. Durra, a variety of the millet, is much used in the countries of India, Egypt, Arabia, and Asia Minor for making bread. Rice bread is the staple food of the Chinese, Japanese, and a large portion of the inhabitants of India. In Persia the bread is made from rice flour and milk; it is called "Lawash."

The Persian oven is built in the ground about the size of a barrel. The sides are smooth mason work. The fire is built at the bottom and kept burning until the wall or sides of the oven are thoroughly heated. Enough dough to form a sheet about 1ft. wide and about 2ft. long is thrown on the bench, and rolled until about as thin as sole leather, then it is taken up and tossed and rolled from one arm to the other and flung on a board and slapped on the side of the oven. It takes only a few moments to bake, and when baked, it is spread out to cool. This bread is cheap (one cent a sheet); it is sweet and nourishing. A specimen of the "hunger bread" from Armenia is made of clover seed, flax, or linseed meal, mixed with edible grass. In the Molucca islands the starchy pith of the sago palm furnishes a white, floury meal. This is made up into flat, oblong loaves, which are baked in curious little ovens, each oven being divided into oblong cells to receive the loaves. Bread is also made of roots in some parts of Africa, and South America. It is made from manioc tubers. These roots are a deadly poison if eaten in the raw state, but make a good food if properly prepared. To prepare it for bread, the roots are soaked for several days in water, thus washing out the poison; the fibres are picked out, dried, and ground into flour. This is mixed with milk, if obtainable, if not, water is used. The dough is formed into little round loaves, and baked in hot ashes or dried in the sun.

PORK AS FOOD.

THE TWO PARASITIC EVILS DEVELOPED IN THE TISSUES OF HOGS.

The prejudice against the flesh of swine as human food is as old as history. If it has any foundation in nature besides the filthy manner in which the hog is generally kept, it is because the hog is more subject to disease, or at least to a certain class of diseases, than other domestic animals. Its omnivorous appetite makes it liable to certain diseases from which the exclusively vegetable-eating animals are comparatively, if not entirely, exempt.

The two evils most complained of are tapeworm and trichina—both parasitic. Both of these are developed in the animal tissues, and it is very doubtful if they ever afflict animals that do not eat animal food, or in some way get animal products into their stomachs and intestinal canals.

The tapeworm, when encysted in the tissues of the hog, has the name of measles—though wholly unlike measles in the human species; the pork containing these encysted worms is known as "measly pork." When taken into the human stomach, they are liable to develope there in the form of the loathsome creature known as tapeworm. This is not necessarily fatal, but very annoying. In modern times, it is successfully removed by the skilful physician without pain or injury to the patient.

TRICHINA

is a parasite much more to be dreaded even than the tapeworm. It is liable to infect the human system in such numbers as not only to be very painful, but fatal, and we believe there is no known remedy. It is encysted in the flesh of the animal, in a dormant state, like the tapeworm. When the trichina enters the human stomach, it attaches itself to the mucous membrane and there awakens to all the activity of breeding thousands, if not millions, of its kind. These young trichina at once start out to find a place in which to encyst themselves for a dormant rest and await a resurrection by having the flesh in which they are imbedded eaten by some animal, brute or human, when they will repeat the *rôle* of their progenitors.

It is when passing from the stomach and intestines to the muscles that the trichina give such pain, and frequently cause death. Pushing their way through the tissues, they cause great irritation and inflammation, resulting in death when the effects become unendurable. While in this active state of migration, seeking a home, they are as liable to be found in one class of tissues as in another. Hence, lard that has not been exposed to a heat of at least 212 deg. Fah. is just as likely to contain them, if the animal was killed when the trichina were in a state of activity, as in any other part or product of the hog.

THE ONLY WAY TO AVOID THE EVIL

and suffering from tapeworms and trichina is to either wholly abstain from eating pork, or to be sure that it is thoroughly cooked so as to destroy the vitality of the encysted parasite. The muscle of the hog makes exceedingly palatable food, and many enjoy eating the fat. In spite of all the terrors and drawbacks, pork is a common and popular article of food. So long as animal flesh

continues to be eaten by man, we presume pork will be eaten. As there is no cure for one of the diseases imparted by it, the safety of the public health demands that hogs be kept in a cleanly manner, fed only on vegetable food and such animal products as belong to the dairy, and that the meat—of all kinds, as for that matter—shall be sufficiently cooked to destroy all animal life. Nothing less than subjecting every particle of it to a heat of at least 212 deg. will do it.—*Health.*

THE VALUE OF EGGS AS A FOOD.

Would it not be wise to substitute more eggs for meat in our daily diet? About one-third of an egg is solid nutriment. This is more than can be said of meat. There are no bones, no tough pieces that have to be laid aside. A good egg is made up of ten parts shell, sixty parts white, and thirty parts yolk. The white of an egg contains 66 per cent. water, and the yolk 52 per cent. Practically an egg is animal food, and yet there is none of the disagreeable work of the butcher necessary to obtain it. Vegetarians use eggs freely; and many of these men are eighty and ninety years old, and have been remarkably free from sickness. Eggs are best when cooked four minutes; this takes away the animal taste which is offensive to some, but does not harden the white or yolk so as to make them difficult to digest. An egg if cooked very hard is difficult of digestion, except by those persons possessed of stout stomachs; such eggs should be eaten with bread and masticated very finely. An egg spread on toast is fit for a king—if kings deserve better food than anybody else. Fried eggs are much less wholesome than boiled ones. An egg dropped into hot water is not only a clean and handsome, but a delicious morsel. Most people spoil the taste of their eggs by adding pepper and salt. A little sweet butter is the best dressing.

FOOD STANDARDS.

The following food standards have been recommended for adoption by the Board of Health of New South Wales:—

"Milk shall contain not less than 12¼ per cent. of genuine milk solids, of which at least 3¼ per cent. shall be butter fat; the milk solids to be obtained by drying any convenient quantity of the sample on a water-bath for three hours until constant in weight. Then upon substraction of 3¼ per cent. of fat the remainder shall be taken as the coefficient of 'solids not fat,' and shall be at least 9 per cent.

"Butter shall contain not less than 83 per cent. of genuine butter fat.

"Tea shall not contain more than 8 per cent. of mineral matter calculated on the tea dried at 100 degrees Cent., of which at least 3 per cent. shall be soluble in water, and the tea as sold shall yield at least 28 per cent. of extract.

"Vinegar shall contain not less than 3 per cent. of acetic acid ($C_3H_4O_3$) and not more than one-thousandth part by weight of sulphuric acid.

"Spirituous liquors, brandy, whisky, and rum shall not be more than 25 per cent. underproof. Gin shall not be more than 35 per cent. underproof."

FOOD POISONING.

"A saying that is literally true," remarked a physician the other day, "is that setting forth the doctrine that one man's meat is another man's poison. Within a short time I have treated two curious cases of what I may term eruptive indigestion. In the first I chanced to meet the man on the street in the morning. He was apparently perfectly well. At five o'clock I was summoned to his residence. I should not have recognised him, so distorted were his features from the eruption which covered them. Investigation and the future history of the case settled beyond a doubt that the man had been poisoned by cockles, which he had eaten at luncheon, yet the disturbance was for him alone, other members of the family who had partaken of the same dish, feeling no ill results. A fortnight later, another patient of mine came to me with a marked eruption on hands and wrists and between the fingers. A dinner of veal was responsible for the trouble, and again, as in the first instance, the sufferer was the only one affected of the family who had partaken of the meat at the same meal. In each case I found that the tendency to distress from the particular food was known to each sufferer, although never before had the symptoms been so marked or distressing. This is, perhaps, a word of warning to persons who know their poison to abstain from it, particularly when their systems may be from some cause in a non-resisting state."

THE DISINFECTION OF BOOKS.

At a recent discussion of this subject, Dr. John S. Billings, the director of the New York Public Library, said, in part:—"At an investigation made by the State Board in Iowa three years ago it was found that six cases of scarlet fever were undoubtedly communicated through circulating library books. Other diseases may be communicated in the same way. There is not much danger of this from the edges of cards, although they are foul and filthy, and undoubtedly filled with bacteria, more especially with those of skin diseases. In order to prevent any possibility of the diseases through books it is necessary to destroy the bacteria.

"We cannot use the method of applying 210 deg. Fah. of dry heat. That would curl the leaves and injure the bindings. Much less can we apply 212 deg. Fah. of wet heat. We cannot apply a solution of corrosive sublimate or zinc chloride. The fumes of burning sulphur are both inadequate and undesirable.

"Two years ago, when in Philadelphia, I suggested to one of the fellows in the laboratory that it would be desirable to seek a new method. Formaline was known to be a destroyer of bacteria, and he set to work on that. This can be purchased in a drug store, or may be made by burning methyl alcohol. A saucer of formaline, a book which had been infected with the bacteria of diphtheria, another with scarlet fever, and another with erysipelas were placed under a bell jar. The experiment showed that one cubic centimetre of formaline to 300 cubic centimetres of space would thoroughly disinfect any book in fifteen minutes."

MEDICINAL USES OF COFFEE.

It is said that the first use of coffee by man was made by the prior of a convent. He was told by a goatherd of the exciting effects of the berries when eaten by his goats; so he thought he would try them and see if he could not keep his monks awake during what should have been their vigils. He succeeded admirably, and brought coffee into the way of earning its world-wide reputation. The most active principle of coffee is caffein; it contains also certain oils, which no doubt have a share in its action. Many years ago a claim was made that green, or unroasted, berries had a great value in liver and kidney troubles. One enthusiast prefers a mixture of two parts Mocha and one part Martinique and Isle de Bourbon coffee. He puts about three drachms of this in a tumbler of cold water and lets them strain and infuse over night. The next morning, after straining, the infusion is taken on an empty stomach the first thing after getting up. This medical authority cites many cases of kidney and liver colics, diabetes, nervous headaches, &c., which, though rebellious in all other treatments for years, soon yielded to the green coffee infusion. The remedy is a very simple one, and well worthy of a trial. Another use of coffee medicinally is in nausea and retching. For that purpose a strong infusion is made of the berries which have been ground and roasted, and it is sipped while very hot.—*Family Doctor.*

NUTRITIVE VALUE OF MEAT EXTRACTS.

C. V. Voit (*Münch. Med. Wochensch.*, 1897, No. 9), maintains that "extracts" are merely "Genussmittel," stimulants or condiments. Dr. Lauder Brunton considers them poisons if taken in excess, and that though some do contain a variable proportion of nutritive substances as peptones, albumoses, and glykogen, the quantity that can be ingested in these forms is practically insignificant. Only the peptonised meats can be considered foods, and Leube's alone consists of soluble myosin, without any admixture of the comparatively useless gelatin, or of mere "extractives," which are but waste materials of the creatine series.

VEGETARIANISM AND QUEEN ELIZABETH.

The editor of the *Lancet* has been favoured with a letter from a lady who uses "Stella" as a pseudonym, and who denounces him as blood-thirsty and indecent because he does not, on the one hand, espouse the cause of vegetarianism, while on the other he neglects to insist upon the employment of women only to attend upon sick women. Our contemporary's rejoinder will, we imagine, hardly propitiate "Stella":—Our correspondent is terribly in earnest, but in her anxiety to get in her telling blows she leaves herself a little unguarded. Can we deny, she asks, that tuberculous meat is a source of danger? No, we cannot; but can "Stella" deny that milk is also a vehicle of tuberculous infection? and milk, we fancy, is an important constituent of the vegetarian diet. Can we contradict her, she asks, when she states that women are competent to wait on suffering women; and if not, why do we not put aside our intolerance and denounce "the gross impropriety of male ministration?" To this we would remark—regretfully—that it requires a nasty mind to see the impropriety that is so gross in "Stella's" opinion; and that to insist upon every woman having a woman to attend upon her would be a very intolerant proceeding, for some of "Stella's" suffering sisters might prefer the services of the opposite sex. Finally, "Stella" asks us to "look at Queen Elizabeth!" Despite its abruptness this may not be an inconsequent request, though we cannot see its bearing. We make no claim to a perfect knowledge of historical matters, but if "Stella" is meaning to adduce Queen Elizabeth as a proof that a woman can make a good ruler, we think a better example could be found in times that are nearer to us. And if "Stella" means to imply that Queen Elizabeth was a successful monarch because she was a vegetarian, we escape all discussion of the deduction by denying the premise. Putting aside the particular case of Queen Elizabeth, imagination staggers in the attempt to realise the reign of a queen whose policy should be swayed by her vegetarianism. We recommend the theme to Mr. W. S. Gilbert.

Novel Way of Preserving Meat. — Anyone who has ever picked up with a bare hand a piece of intensely cold iron, knows that the touch burns almost as badly as if the metal were red hot. Indeed, the action of great heat and that of extreme cold are so familiar that a Hungarian chemist has turned the latter to account to prepare meats for food. He subjects the meat to 60 deg. of frost and then seals it up in air-tight cans. The result is that the meat, which is practically "cooked by cold," will keep any time, and can be eaten with very little further preparation.

Food and Health

SUPPLEMENT TO

THE SANITARY RECORD.

No. 14. MARCH, 1898.

FOODSTUFFS UNDER SCRUTINY.

WHAT TO EAT AND DRINK, AND WHAT TO AVOID.

"SANITARY RECORD" ANALYSES.

IMPORTANT ANNOUNCEMENT.

OWING to the growing popularity of this feature of our "Food and Health" Supplement, we have found it necessary to make arrangements whereby, in future, much fuller reports will be given of proprietary articles than have appeared hitherto. It has been our custom to solicit samples of articles for investigation from the manufacturers direct, unconditionally; but in future such samples as we receive from the proprietors thereof will require to be accompanied by a declaration that the sample is selected from stock, and not put up for the special purpose of analysis. Failing this we shall make the purchases ourselves, selecting the articles at random from the various retail establishments where they are sold.

We have retained the services of Mr. C. G. Moor, M.A., to examine and report on the various substances submitted to us.

All such analyses may of course be quoted as having appeared in THE SANITARY RECORD, but the date must be given, and Mr. Moor's name must not be quoted for advertising purposes without special permission.

"D. C. L." Malt Extract.

I HAVE duly examined the sample of malt extract prepared by The Distillers Company, Limited, of Edinburgh. My results are as follows:—

Maltose	52·5
Dextrin	13·6
Albuminoids	7·4
Mineral matter	1·9
Water (diastase, &c.)	24·6
	100·0

The sample was absolutely free from poisonous metals.

The mineral matter contained ·34 phosphoric acid, calculated on the original sample.

The value of a malt extract depends largely on its diastatic power, which in the case of the present sample is very considerable. This fact, coupled with the very palatable character and purity of this product, places it in the first rank among similar preparations.

Hay's Food for Infants and Invalids.

I HAVE duly examined the sample of Hay's Food for Infants and Invalids (prepared by William Hay, Manufacturing Chemist at the Hygiene Flour Mills, Hull), with the following results:—

Moisture	8·1
Carbohydrates, &c.	74·8
Albumenoids	13·7
Mineral matter...	1·3
Fat	2·1
	100·0

The mineral matter consists of the phosphates of calcium and potassium. About 13 per cent. of the food is soluble in cold water, and after examining the matter insoluble in cold water by the ordinary acid and alkali treatment there was no insoluble fibre.

Its absence is important, as there should be no irritating particles in a food intended for infants.

The flavour of the food is very good, and when prepared according to the directions on the tin it should be readily assimilable and of high nutrient value.

THE MEAT SUPPLY OF PARIS AND ITS INSPECTION.

By EDWARD CONNER.

THE meat trade is indeed the most important alimentary industry of Paris. Its operations are vast, yet the organisation is, relatively speaking, not complicated. Paris requires annually 83,000 tons of beef, 38,500 of mutton, and 18,330 of veal. It is besides supplied with 22,000 tons of pork, but the pork dealers or *charcutiers*, numbering 1100, are not accepted as butchers; besides, they have their own separate guild. The total number of butchers in Paris is 2517; they are divided into three classes—wholesale, demi-wholesale, and retail. The butcher who buys the fat cattle on foot, kills and dresses the meat, is a wholesale butcher or *chevillard*—so-called from the name of the iron hooks in the hall from which he suspends the carcases to cool and acquire an initial firmness. There are 287 of these wholesale butchers. Custom has established three categories of beef, and two for mutton and veal. It is expected that the two halves or moieties of the carcase of an ox, or net meat, will cover the

cost of purchase; the fat and the offal, known in Paris as the "fifth quarter," constitute the profits of the wholesale butcher. Except for pigs, stocks are not purchased by weight as a rule; the buyer relies on his skill and experience. As the trade in all its grades is entirely free, it is impossible to gauge a butcher's gains. However, a few in the year become bankrupt, so the business has its drawbacks. A farmer can kill his own meat and send it for sale to Paris, but as a rule that practice is not adopted. Meat can also be sold by costermongers in the streets during certain fixed hours of the day. In every case the sanitary inspection of meat throughout the city is very rigid.

La Villette is the Paris Smithfield cattle market. Though open daily except Sunday, Mondays and Thursdays are the principal sale days, and the hours between ten and three o'clock. Since the protectionist decree of 21st February, 1895, no American cattle are admitted into France; she can supply her own wants, chiefly at the weekly fair of Cholet, situated between Anjou and Vendée, and known as the "beef granary" of France. The cost of transporting a fat ox from La Plata to La Villette is 140f. La Villette received in 1895, 293,610 head of cattle, of which 3771 were foreign; 166,734 calves; 1,667,862 sheep, of which 422,097 were foreign; and pigs, 431,846, of which 2352 were imported. But all the live stock arriving at La Villette are not destined for Paris wants; the northern and eastern cities of France also draw a good deal of their supplies here. German sheep are not considered so good as formerly; those from Hungary are too fat. However, mutton being so dear of late, housekeepers buy less. South American cattle are ranked as inferior, and, being cheap, are purchased mostly for the use of the French army. Holland contributes small pigs, between 1½ cwt. and 2 cwt., but which are not in demand. The system now coming into use at La Villette is to pay ultimately for the beast according to the price the dressed meat will realise per lb., offal excluded. Thus, say, a fat ox is purchased per live weight at 140f. per 100 kilos., or double hundredweight, the exact cash down will be based on what the four quarters net will realise. Calves and sheep are always thus sold, but the price for pigs is lumped on foot.

There are about 287 wholesale, and 2230 demi-wholesale and retail butchers in Paris. The La Villette abattoir employs a total of 2562 hands, of whom 142 are women. It possesses 209 slaughter-houses, or *échaudoirs*, each capable of preparing five carcases per day; any butcher can rent one, kill his own cattle, and retail the meat in his own shop. Before entering the slaughter-house, the animals are again examined; it is thus that 1120 were rejected in one year. The custom is for the wholesale butcher, after the carcase is dressed, to have its halves or moieties transported into a vast cooling hall, to allow the meat to become firm—a matter of six hours. Each lot of meat is numbered with a docket, and is next inspected by the veterinary surgeon. If found to be sound he stamps the meat with a "V"—which means *vu*, proof of his examination—in blue colour. If any be insalubrious it is rejected, some is retained for the tenants of the Zoo, the rest is sprinkled with petroleum and delivered at the knacker's yard for industrial purposes. The meat is next weighed, replaced on the hooks or *chevillards*, with a docket pinned thereon setting forth its weight. The public sales then commence; the retail master butchers select what is best, and at a price debated with the owner or wholesale butcher, the conditions being registered by a clerk at the same time. All cattle entering the La Villette market, which adjoins the abattoir, must pay a tax down before it is allotted standing space; the charge for cattle is 10f., calves 12f., sheep 15½f., and pigs 8f. per 100 kilos., or double hundredweight (live weight); there is also a small tax per head for sanitary inspection and cleansing the markets. The octroi dues are included in these tolls. If any animal be unsold, such are viewed as being only *in transitu*, and have but to meet a board and lodging tax. After the big butchers make their purchases in the cooling room, the rank-and-file strike in; they generally buy secondary meat, or joints specially cut up, but not weighing less than 16 lb. The total number of salesmen—not guaranteed as to solvency—is 115, of whom 49 for cattle, 15 for calves, 32 for sheep, and 19 for pigs. Their commission varies per head—cattle 3f. to 5f., calves 1½f. to 2f., sheep 30c. to 50c., pigs 75c. to 2f. The value of all the sales in a twelvemonth amounts to 281 million francs.

There are 245 special vans, which are the property of an independent company, for the delivery of the meat to the large purchasers. Painted on the outside is the weight of the vehicle, and the *brut* weight it can load up to. Arrived at the exit gate of the abattoir, the cart passes over a weighbridge, when the tax inspectors register the weights. The toll is 9f. 73c. per 100 kilos. of meat, plus 2f., per same weight for the right of slaughtering. All this taxation is, of course, municipal, and includes a fractional levy to defray the cost of the erection of the market and abattoir. The branch abattoirs where all animals entered must be killed, are conducted on the same lines as that of La Villette, save that only cattle, sheep, and calves are killed at that of Grenelle, pigs exclusively at Fourneaux, and cattle and horses at Villejuif.

There is another important department of the dead meat market at La Villette, outside of what may be called the Cooling Hall sales, and known as the *marché du réassortiment*. It is fed by deliveries of slaughtered meat from the ordinary *échaudoirs* from the suburban butcheries, from consignments from the provinces and foreign importations. Switzerland in 1895 sent 12 tons of sirloin beef, and that realised 10½d. per lb. The total supply of this dead meat sold in a year was 5218 tons, most of it having been received during the months of May and July; of this, 3951 tons were beef, 723 tons veal, 538 tons mutton, and 7 tons pork. The meat on its entry is inspected —6 tons were rejected in one year as being unsound — weighed, and docketed, then struck with a storage or stall tax of 2f. 10c., plus 20c. per same weight, for cutting up. The direct meat consignments having entered Paris, paid the octroi dues at the fortifications, the rest at the abattoir. There are twenty-one salesmen for this special branch. The buyers—mostly small butchers, and second and third-class restaurant keepers—have to bring away their purchases themselves.

But the Halles Centrales are the great wholesale

dead meat market, and which is held in pavillons 3 and 5. It has no connection with the kindred market at La Villette, except that the abattoirs send meat to be sold here. The sales, whether by private bargain or public auction, take place in summer and winter, at five and six o'clock in the morning respectively. The auctioneering ceases when there is no more meat to sell, and that by private bargain, at eleven. All the meat is weighed and inspected—250 tons of meat in 1895 were condemned as being unsound—one hour before the opening of the market. The provinces and foreign countries supply 73 per cent. of all the meat sold here; the abattoirs, 16; town butchers who buy to re-sell, 7; and the suburbs, 4. The total toll for meat leaving the abattoirs is nearly 11¾f. per 100 kilos. If the meat be sent to the Halles Centrales, it is submitted to a further tax of 2f. 30c. per 100 kilos. This impost yields 984,016f. yearly. In a word, one-third of all the meat entering Paris is sold at the Halles Centrales, and which amounts annually to 38,000 tons. Of this quantity, 2000 tons were strictly imported, 375 from Switzerland, and 11 from Australia. The average price per lb. obtained for the beef was nearly 11½d., and for mutton 1s. 1¾d. of the total sales, 82 per cent. was disposed of by private bargain, and 18 by public auction. In summer especially, 2 per cent. of the choicest morsels are purchased for the seaside resorts. There are sixty-two *mandataires* to conduct the sales. The German and Swiss meat railway vans have false sides to admit of being filled with ice in warm weather. It is the Great Northern Railway Company of France that transports the slaughtered sheep from Berlin and Magdeburg; over the German lines only the carcases are carried by fast trains. On arriving at Jumont, on the French frontier, the mutton is inspected by vets.; 300 carcases can be thus dealt with in eighty minutes. It costs 37f. per ton of carcases from Jumont to Paris. The train arrives in the morning at four o'clock; some butchers purchase direct from the railway wagons, and thus economise the toll at the Halles Centrales, to where the bulk of the meat is sent—about two-thirds of the consignment. Frozen mutton from Argentina is landed at Hâvre, where a little of it is consumed, as also at Rouen and Dunkerque, but the bulk is forwarded on to Paris. The entry duty on Argentina mutton is 13f. 50c. per 100 kilos., while that on German carcases is but 4f.

The consigners of alimentary products from the provinces have had a long-standing grievance against the salesmen of the Halles—and known as *Commissionnaires* and *facteurs*—respecting the vending of their consignments; the charges were excessive, disproportionate to remittances, and the latter unpunctual, or worse. All that has become ancient history since the new regulations have just come into operation, and whose working is under the control of the Prefect of Police. Henceforth, every commodity sent for sale must be sold in the pavillon especially allotted to such, but cannot be admitted if below a minimum quantity. In other words, only wholesale and demi-wholesale transactions will be tolerated. There is but one category of salesmen now recognised here, who are known as "*mandataires*." A list of candidates for this function is registered at the Tribunal de Commerce; if the applicant is accepted—the number is limited—he will receive a certificate or licence. The list of *mandataires* is always free for public inspection; if a member be guilty of any dishonourable conduct the Prefect of Police can demand his dismissal. After hearing the accused, the Tribunal can definitely decide for his name being struck off the register. No *mandataire*, even when chosen, can act till he possesses a booth or stand in the pavillons for the meat sales, and deposits a *bonâ fide* security for 5000f. at least, and augmenting each year following the importance of his business. The *mandataire* is bound to strictly follow the instructions of his customer. All sales must take place strictly within the pavillons; proceeds to be remitted on the day of the sale even, or the next day at latest, to the sender, unless a special arrangement exists otherwise. The *mandataire* must be present at all sales, and cannot be replaced by another colleague. He is free to accord, at his own risk and peril, credit to buyers, but must all the same remit immediately to his client full amount of sales. Out of these proceeds will be deducted certain market charges following the published tariff, but rate of commission is optional between the *mandataire* and his customer. The farmer must record the details of his sales, as to amounts realised and names of purchasers. The authorised agents of the Prefect of Police are to have free access to examine the records, in case of any dissensions between customers and salesmen. It is evident that there can be no fraud; they are the officials of the Municipality—who have no connection with the Custom Officers—that levy the dues for the octroi, on live stock, and dead meat entering the capital, as well as the charges for the *réassortiment* or morselling of the meat, either for purchase by private bargain or by public auction. The client is aware what the transport of his meat will cost by rail, &c., to the Halles Centrales, and the tariff of market tolls; he is left free to arrange with the salesman as to fee for commission; the latter is bound to follow implicitly the instructions of his client, to remit account and proceeds of sales within twenty-four hours, and the client can claim to inspect the register of the sales of the *mandataire*, who in case of dishonesty risks his certificate, while for non-remitting, his surety deposit of 5000f. can be impounded till the liability be paid in full.

UNTOWARD EFFECT OF EATING RAW STARCH.

Dr. L. Kahn reports in the American *Therapist* the case of a girl aged 20, in which great anæmia and some heart trouble were coincident with the practice of eating raw starch. Her history for the previous eighteen months was that she started her peculiar habit by taking lumps or pieces of starch from the box as she passed it three or four times daily; this gradually increased till she was using it regularly every few hours with a teaspoon. Her mother noticed the disappearance of the starch and watched for the cause; discovering her daughter's habit she stopped the supply. The starch habit lasted about six months. Then the starch being no longer obtainable she started on flour, first using a teaspoonful twice or thrice daily, gradually increasing till she used two teaspoonfuls every hour when awake. Under tonic treatment, the practice being discontinued, the patient had greatly improved and continued to progress.

DEATH IN MILK.

SOME REVELATIONS ABOUT TUBERCULOSIS

In a recent address before the Cheshire Chamber of Agriculture, Dr. G. Sims Woodhead, director of the Laboratories of the Royal College of Physicians and Surgeons, London, gave some startling details in regard to the prevalence of tuberculosis in the cattle of Great Britain.

Dr. Sims Woodhead said his subject was one which, not only in this country, but in all countries in our northern latitudes, had long occupied the attention of those interested in the prevention of the spread of infective diseases, and they had come to take a true view of the nature of tuberculosis, and were enabled to apply rules by which the disease might be diagnosed and its spread prevented with almost absolute certainty. It was one of the most important subjects with which raisers of stock and dairy farmers had to deal. It was recognised that milk from tuberculous animals had the power of setting up most active tubercular processes. He did not wish to express any alarmist views, but rather to lay down certain well-defined and accepted facts, and they would be in a position to see how many of these cases might be absolutely prevented.

Dr. Woodhead proceeded to detail the features of tuberculous disease as it occurred in man and animals, mentioning that the lungs and intestines were usually affected. These were parts that were from time to time in relation to the outside world, the lungs through the air, and the intestines through the food that passed into them. In regard to milch cows, there were many dangerous cases where the disease was not suspected, and where the udder might be affected without there being any definite sign in the earlier process of the disease. Milk was a diet which in ordinary circumstances was not submitted to processes of cooking. It was

BECAUSE SO MUCH UNBOILED MILK WAS DRUNK

that the danger arose. Dairy cattle should be kept under rigorous observation. It was long supposed that such animals as cats and horses were not liable to contract the disease. This was not so. The horse had been known to contract tuberculosis just as did pigs that were fed with milk from tuberculous cattle. The cat took it as the cattle did, and as older human beings did—through the air. The tuberculosis of children was almost invariably contracted through the intestines.

Treating of the extent to which animals are affected by tuberculosis, the lecturer said that in Copenhagen, where the cattle were stringently inspected, of the cattle killed in the four years 1890—93, inclusive, numbering 132,294 oxen and cows, 23,305, or 17·6 per cent., showed evidence of tubercular disease. Of 8292 pigs, 1272 were tuberculous; while of calves, there were out of 185,765 examined only 369, or less than one-fifth per cent., that showed any trace of tuberculosis. The disease in sheep was exceedingly rare, as out of a third of a million of sheep only one was found to be tuberculous. In the Berlin slaughter-houses similarly inspected 15 out of every 100 cattle were found to be tuberculous. The number of pigs so affected was only 1½ per cent., and of calves only about one-tenth per cent. Whatever statistics were taken, they found the figures were fairly approximate. It was sometimes said that we had not tuberculosis to anything like the same extent in this country, but from personal experience he knew that we had. He had, for example, seen a herd of pedigree stock which was

TUBERCULOUS ALMOST FROM END TO END.

In Edinburgh in 1890, where 300 milch cows had to be slaughtered owing to pleuro-pneumonia, it was found that 120, or 40 per cent., were tuberculous. In one case the cows affected were in the proportion of 83 out of 100. The very small percentage of calves affected would be observable in comparison with cattle and pigs. We were sometimes told that tuberculosis was hereditary. If that were so we might expect to find more calves affected. With regard to the liability of milk or meat to convey tuberculosis to human beings, the lecturer pointed out that the tubercular kernels were found in almost every part of the body. Wherever there was a gland affected there might be tubercular focus. In experiments even with cooked meat, a small proportion of animals fed with it had contracted the disease. If only 1 per cent. were affected, they would represent a vast number of human beings who might contract the disease. The bacilli, however, were not in the meat itself, as a rule, but in the glands and various organs, and in the covering of those organs as they lay in the chest or abdomen. Inspection and cooking were undoubtedly safeguards when well carried out. It was better from every point of view that preventive measures should be taken at an early period. Tuberculous milk was a subject of more far-reaching import. He could not help attributing the affections of glands in the neck which occurred in many weakly children to the consumption of milk from

COWS WITH TUBERCULOUS UDDERS.

He also attributed to the same cause a large number of cases of inflammation of the bowels amongst children. The importance of keeping the sources of milk supply untainted could hardly be over-estimated. He was convinced there could be no tuberculosis without the presence of the tubercle bacillus, and that the disease was transmitted only through the agency of this bacillus, and therefore he was of opinion that heredity in the ordinary sense of the term could account for very few, and practically none, of the cases in either the human subject or animals. Of course, there were cases of congenital disease, but hereditary tuberculosis he did not believe in. Dr. Woodhead said that tuberculosis was preventable, and, if proper steps were taken, would be reduced to a disease of comparatively slight importance. One thing we could do, and that was carefully to keep away from all our dairies or farms any people suffering from tuberculosis. No person suffering from tuberculosis should be allowed to have anything to do with the care of cattle or the preparation, collection, or distribution of our meat or milk supplies. All measures for the maintenance of health in animals were inimical to tubercular bacilli.

Dr. Woodhead, in conclusion, recommended as

principal methods of getting rid of tuberculosis, systematic and regular inspection; the use of tuberculin, in which, he said, they had a diagnostic agent infinitely superior to any ever before at their command; notification, in order that measures might be taken in consultation with those specially interested to do the right thing with the animals, whether to be slaughtered at once or kept under observation, or, in cases of breeding, to see the conditions under which the animals should be kept. There should be isolation in the case of every tuberculous animal, and there should be plenty of ventilation and light in the shippons. The animals should have good food, and be kept under generally

FAVOURABLE HYGIENIC CONDITIONS.

The registration and inspection of dairies would afford confidence to the public. There should be disinfection, and he believed we should have to come to the marking of meat, as in countries abroad. There should be compensation to owners whose animals had to be destroyed. Tuberculosis should be scheduled as infective, and the compensation should come from a fund to which Imperial and local assistance might be given, and the owners should also contribute. He believed that by adopting such measures a series of regulations might be drawn up which would help not only themselves but the whole country.

POINTS IN MEAT INSPECTION.

THE CHARACTERISTICS OF MEAT.

Good meat is of a bright colour, marbled with fat; the flesh of a calf is always paler and less firm to touch; mutton is a dullish red, firm, the fat hard, usually white; but a marked yellowness is consistent with wholesome meat; the flesh of a pig is paler and less firm to touch, the fat is always soft, the carcase should be plump, the skin smooth, not set in folds or wrinkles.

The chief points to which special attention should be paid are: The colour of the exterior of the carcase, called by butchers the "bark," in diseased meat it is very pale, instead of its resembling the colour of a plum; emaciation and wetness of the flesh; soft and flabby condition of the flanks; the inside and outside should be examined; the breast, underneath the arms and shoulders, behind and about the kidney fat, under the skirting, as it is in these situations that dropsical lesions are usually located; evidence of such disease as tubercle is frequently found in these parts; the walls of the chest should be carefully examined, to detect any stripping; the stripping of the pleura or lining membrane of the chest, is practised for the purpose of removing traces of pleurisy and tubercle; also for the purpose of removing the unsightly appearance of the blood in the chest, which is due to over-sticking and accidental pouring into the chest the contents of the stomach and intestines.

If these traces have been removed for the latter purpose only, the underlying issues will be found firm and dry, and of their normal colour, except the rugged portions may be a little stained with blood; if the process has been carried out to remove traces of the disease, the muscles will be found soft and moist, and much paler in colour, and the fat tallowy. This stripping is often done very cleverly, and hot fat rubbed over the walls of the chest, so as to try and hide traces of the disease.

Spencer E. Jones.

TUBERCULOUS POULTRY AS FOOD.

A correspondent has communicated to the *British Medical Journal* a disquieting occurrence which recently befell him. The cook, when she came to dress the Christmas turkey, thought the liver "looked bad," and put it aside. The bird was cooked, and was partaken of by a party of children. Our correspondent found the liver of the turkey (which had been supplied by an important firm) to be "studded all over with tuberculous masses," this diagnosis being confirmed by microscopical examination. On inquiry, he found that the bird had been reared in one of the home counties, where the firm bought annually over 2000 turkeys.

The story is unpleasant, but it is reassuring to know that, according to the present state of knowledge, there is not much ground—though the question cannot be said to be quite settled—for believing that avian tuberculosis can be transmitted to man by ingestion. The experiments of Strauss and Wurtz and of Strauss and Gamaleïa seem to show that birds are almost immune to tuberculosis of human origin. Rivolta and Maffucci have found that tubercle bacilli of avian origin have only slight pathogenic properties in regard to mammals. Koch himself has insisted upon the cultural differences between the two bacilli. On the other hand, we know that Gilbert, Roger, and Cadiot have been able to produce tuberculosis in rabbits by inoculating them with the avian bacillus. The same authors have also shown that hens may, under certain conditions, be infected with the human tubercle bacillus.

These results have been confirmed by Courmont and Dor, Nocard, Delépine, and, we believe, also by Macfadyean. The guinea-pig, which is so easily affected by tuberculosis of mammals, is very resistant to avian tuberculosis, but is not so immune as some believe. We must therefore admit that avian tuberculosis may occasionally be transmitted to mammals. All our domestic birds (common fowls, turkey, guinea-fowl, peacock, pigeon, pheasant, &c.) are liable to it; indeed, epizoötics may occur in poultry yards, and entail serious pecuniary losses. Once a place has been infected the disease becomes enzoötic, and is very difficult to eradicate unless all the birds in the poultry yard are destroyed, and the place thoroughly disinfected.

It is easy to understand this feature of the disease. Birds are usually infected through the alimentary canal; when a bird is tuberculous its excreta after a time teem with tubercle bacilli; the soil, straw, food, water, perches, nests, walls, &c., are rapidly soiled with these excreta, and in this way the bacilli may rapidly find their way into the alimentary canal of any number of birds. Even admitting that there is some danger of the disease being communicable to man, it does not seem likely that it would be communicated by ingestion. When a fowl is "cleaned" previous to cooking, the organs usually

affected with tuberculous lesions (liver, spleen, intestine, peritoneum) are removed more or less completely. A cook would usually have no difficulty in recognising that a liver in a marked state of tuberculosis is diseased, and not fit for food. Birds are usually cooked very thoroughly. It is true that occasionally tuberculous livers may have been prepared for food. Moulé has recorded a case in point.

In a village where fowl tuberculosis was very prevalent, people were in the habit of preparing a paste with livers in an early stage of the disease. They were under the impression that the tuberculous lesions were indications of fatty changes, and, under this impression, they considered that these *foies gras* were great delicacies, and they partook of them accordingly. Indeed, all *paté de foie gras* is under suspicion. Still, admitting the possibility of transmission to man, we must look for danger in another direction.

It is evident that the contamination of the soil and various objects with excreta teeming with bacilli will cause the dust raised from an infected place to be loaded with these. It must be remembered also that the avian bacillus is capable of growing rapidly outside the body. It is not an obligatory parasite, and can be grown on vegetable substances even at a temperature much below that of the body. It is not killed by drying. We know so little of the changes to which this bacillus is liable when growing outside the body that we are as yet unable to say if it is capable of acquiring special virulent properties under these conditions, and whether this dissemination of tuberculous dust constitutes a serious danger to man or some of the domesticated animals. So far we have no clear evidence of the existence of such a danger.

HAY'S FOODS.

HAY'S FRUMENTINE.

TO YOUTHS, ADULTS,

and to all who wish to excel in athletic exercises, such as CYCLING, BOATING, CRICKET, FOOTBALL, &c. &c. Try, either in the form of Porridge, or as a thickening for SOUPS, GRAVIES, &c. &c., the delicious and invigorating qualities of HAY'S FRUMENTINE.

HAY'S INFANTS' FOOD

TO EXPECTANT MOTHERS.

It is of the highest importance that, in order to lay the foundation of a vigorous, mental, and bodily constitution in after life the infant should during its Ante-Natal Existence receive the best and most beneficial maternal impressions. The attainment of this desirable object will, therefore, best be accomplished by attention to your own health, moderate exercise, cheerful society proper care of the digestive organs, and by adopting a Porridge diet of HAY'S delicious and LIFE-IMPARTING FRUMENTINE.

HAY'S FRUMENTINE.

TO NURSING MOTHERS

who can bring up their children in the natural way,

USE HAY'S FRUMENTINE,

which imparts Life, Stamina, and Nourishment of priceless value to both mother and infant.

PRICE 6D, IN 2 LB. PACKETS.

HAY'S INFANTS' FOOD

TO THOSE MOTHERS

less favourably constituted and who desire to feed their Infants on a bone, muscle, and brain-forming Food that will produce

A VIGOROUS GROWTH OF THE BODY GIVEN THEM

DR TIBBLES' Vi-Cocoa

DR TIBBLES' Vi-Cocoa

The "LANCET" says:

"Vi-Cocoa must be assigned a place in the front ranks of really valuable foods, since it is the embodiment of all the numerous principles contained in Malt, Hops, Kola and Cocoa . . . of distinct value as a restorative and stimulative food."

The "BRITISH MEDICAL JOURNAL" says:

"Vi-Cocoa is a very palatable beverage of great stimulating and sustaining properties."

The "MEDICAL MAGAZINE" says:

"Medical practitioners will find a valuable weapon in Dr. Tibbles' Vi-Cocoa in combating the various conditions of nervous exhaustion and enfeebled digestion. The ingredients of which it is composed are carefully selected, and of undoubted strength and purity."

The "POPULAR MEDICAL JOURNAL" says:

Dr. Tibbles' Vi-Cocoa is an excellent combination of Kola and Cocoa; and it not only gives the nutritious and sustaining properties, but, having Hops incorporated with it, acts as a tonic and is soothing, while the addition of Malt neutralises all the starchy matter, and so considerably assists weak digestions."

From EDMUND A. ELLIOTT, M.R.C.S., L.R.C.P.

"I have tried Dr. Tibbles' Vi-Cocoa, and my patients are very pleased with it."

From Dr. T. H. SMITH, Royal Colonial Institute, Northumberland Avenue, W.C.

"I have much pleasure in testifying to the superior qualities of your Vi-Cocoa over any similar preparation in the market. I do this willingly and unsolicited, as I consider it a great boon to the public. I have personally experimented with the cocoas in the market, and find that the great drawback to all of them was the slow process of digestion and assimilation. The diastase in the Malt not only assists digestion in your Vi-Cocoa, but it also accelerates the digestion of other foods that are taken with the Vi-Cocoa. This I have personally tested, and can therefore speak from actual experience. Its wonderful recuperative power after exhaustion from fatigue is marvellous."

Merit, and merit alone, is what is claimed for Dr. Tibbles' Vi-Cocoa, and the proprietors are prepared to send to any reader who names this paper (a postcard will do) a dainty sample tin of Dr. Tibbles' Vi-Cocoa free and post paid.

Dr. Tibbles' Vi-Cocoa, 6d., 9d. and 1s. 6d. Can be obtained from all Grocers, Chemists, and Stores, or from Dr. Tibbles' Vi-Cocoa (Limited), 60, 61 and 62, Bunhill Row, London, E.C.

Supplement to THE SANITARY RECORD, *April 22nd*, 1898.

Food and Health

SUPPLEMENT TO

THE SANITARY RECORD.

No. 15. APRIL, 1898.

FOODSTUFFS UNDER SCRUTINY.

WHAT TO EAT AND DRINK, AND WHAT TO AVOID.

"SANITARY RECORD" ANALYSES.

IMPORTANT ANNOUNCEMENT.

OWING to the growing popularity of this feature of our "Food and Health" Supplement, we have found it necessary to make arrangements whereby, in future, much fuller reports will be given of proprietary articles than have appeared hitherto. It has been our custom to solicit samples of articles for investigation from the manufacturers direct, unconditionally; but in future such samples as we receive from the proprietors thereof will require to be accompanied by a declaration that the sample is selected from stock, and not put up for the special purpose of analysis. Failing this we shall make the purchases ourselves, selecting the articles at random from the various retail establishments where they are sold.

We have retained the services of Mr. C. G. Moor, M.A., to examine and report on the various substances submitted to us.

All such analyses may of course be quoted as having appeared in THE SANITARY RECORD, but the date must be given, and Mr. Moor's name must not be quoted for advertising purposes without special permission.

Lipton's Extract of Beef.

I HAVE duly examined the sample of Lipton's extract of beef, with the following results:—

Moisture	16·4
Mineral matter	18·9
Nitrogenous matter	54·9
Carbohydrates, &c. (by difference)	9·8
	100·0

The amount of phosphates (3·7 per cent. of the original sample) is the highest I remember to have found in a similar preparation. The extract is not overloaded with salt, and its flavour is very good. Comparing it with many similar preparations, the nitrogenous matter is higher and the moisture is lower. It is a good extract, and will meet with general approbation.

Vejos.

I HAVE examined the sample of Vejos, submitted for analysis by Vejos, Ltd., with the following results:—

Water...	45·8
Nitrogenous matter...	20·2
Carbohydrates, &c.	24·8
Mineral salts	9·2
	100·0

As a vegetable extract it compares favourably with anything of the kind in the market. It possesses much the same flavour as a meat extract, while its claim to be more economical cannot be gainsaid. Its solubility renders it easy of assimilation, and should commend it to those whose digestive powers are impaired.

TUBERCULOSIS AND THE MILK SUPPLY.

PROFESSOR DELEPINE, of Owens College, Manchester, recently read a paper entitled as above at Keswick. Professor Delépine, in the course of his paper, said that at present there was perhaps, in this country, not a herd of cattle or a cowshed of any size which was free from tuberculosis, and there must be very few milkshops from which tuberculosis milk is not issued at times. Yet there was hardly a class of persons who could be said to be responsible for this state of things. Tuberculous cows were sold and bought, in most cases, without there being even a suspicion of their being tuberculous. They carried with them infections into herds or cowsheds. Their milk was mixed with other milk, and all this, or most of it, was done in perfect ignorance and without any intention to defraud. Some enlightened cattle-owners had, it was true, tried to eradicate tuberculosis from their estates, but though in the long run they would reap the benefit of their right action, the initial cost had been such that others had not been encouraged to follow their good example.

Much could be done by private enterprise, but, as a matter of simple justice, it seemed to him evident that the first cost of a general fight against tuberculosis must be borne not only by the raiser of stock, the dairy farmer, the cattle dealer, and the dairyman, but also by the consumers for whose protection measures had to be taken. It might be difficult to enforce the necessary regulations throughout the whole kingdom all at once, but it

should be possible, by stringent measures, applied locally, to get rid of all tuberculous cattle and clear all infected places in, say, a county or a combination of counties. This being done, it would then be possible to make any person introducing tuberculous cattle in such a district responsible for such an act. Having studied the question of tuberculous infection for a number of years, he was more and more convinced that tuberculosis must be considered

A SERIOUS PUBLIC DANGER.

In order, however, that the meeting should be able to judge, he had to bring before them evidence from which they would draw their own conclusions as to the nature and extent of the danger. Professor Delépine proceeded to explain the nature of tuberculosis and its effects on the human system. We had not, he said, even the consolation to think that a disease which produced such frightful ravages was rare, for if we consulted statistics it became evident that tuberculosis must be considered a very frequent disease. Even at the present day, when by improvements, in sanitation the disease was less frequent in the lungs than it used to be, it was found that about one-tenth of all deaths were due to pulmonary phthisis alone. Now, thanks to numerous researches which had been made during the last thirty-five years, we knew exactly how the disease was produced. Before that knowledge had been acquired it was impossible to deal with tuberculosis in an efficient way; there was an almost general belief in the heredity of tuberculosis. It was thought that the disease was transmitted from parent to offspring, and the contagious nature of tuberculosis was overlooked by most, and barely believed in by a few. Now, on the contrary, we had absolute proof that the disease was produced by the tubercle bacillus. The bacillus might penetrate the body in various ways, but the two most important channels of entrance were the air and the food passages. In the case of infants, it was impossible to doubt the importance of the latter channel of infection. Judging from statistics, it was evidently far from unfrequent. Children began to be seriously affected with *tabes mesenterica*—a kind of consumption of the bowels and of the glands attached—only after they had reached the age of six months, *i.e.*, after most of them had begun to be fed on cow's milk, or foods other than the maternal milk. In the first three months of life hardly any deaths could be attributed to tuberculosis; in the second year in more than one-fourth of all the children dying evidence of tuberculosis could be found. We were, therefore, bound to admit the importance of infection through the alimentary canal, and the danger would evidently be proportional to the amount of tuberculosis in cattle. With regard to the prevalence of tuberculosis in cattle, by putting together figures collected in England, France, Germany, Denmark, and Holland, and based on the examination of some 600,000 head of cattle, he found that more than 16 per cent. were reported as having been tuberculous. Some important German returns gave 15 per cent. Danish statistics gave 17·6 per cent. Recently in Manchester Mr. King, the Chief Veterinary Inspector, found on inspection of cattle slaughtered in the Manchester abattoir, and taken as they came, that 41 per cent. of the cows were affected with tuberculosis. The incidence was less in younger animals, in bulls, and in bullocks, and very slight in calves, so that taking all together

ABOUT 28 PER CENT. WERE AFFECTED

with tuberculosis. Those statistics showed the greatness of the evil, but did not show its distribution. It was well to remember that in certain cowsheds where tuberculosis had gained a permanent foothold as much as 80, 90, and even 100 per cent. of the cows were in a tuberculous state. It was, however, fortunate that the milk of tuberculous cows did not usually become infectious unless the udder was diseased; and it was still more fortunate that the udder became affected in a small proportion of tuberculous cattle. Yet it must be remembered that it was impossible to tell when the udder of a tuberculous cow was going to become affected. In Manchester it would appear that about six of thirty-six cows in a state of advanced tuberculosis had tuberculosis of the udder. He examined specially the milk of twenty-four tuberculous cows in a state of advanced tuberculosis, and found that in six of these tubercle bacilli were present in such numbers as to cause tuberculosis in guinea pigs. Details of these observations would be found in Dr. Niven's report on cowsheds. He might say further that in three of these cases he himself had an opportunity of examining the udder, in which he found tubercles; in two more the Veterinary Inspector reported the presence of tuberculous lesions; in the sixth case it was not possible to obtain certain information. So that unmixed milk taken from tuberculous cows specially selected from among cows kept in Manchester byres proved to be capable of causing tuberculosis in 25 per cent. of the cows examined, and in nearly all, if not all, these cases the udder was affected by the disease. Evidence of this kind showed that we had to deal with a real danger. It was, however, seldom that the unmixed milk of a tuberculous cow reached the consumer, except in the case of children and invalids, and it might be urged that, after being diluted with good milk, the tuberculous milk ceased to be dangerous. This point had been tested both in Manchester and Liverpool, and as he had assisted the Medical Officers of Health in this work he was able to say what he found. The milk was collected at the railway stations immediately on its reaching town, and examined at once in his laboratory. He found that not less than 6 to 7 per cent. of the specimens examined were capable of producing tuberculosis—sometimes very rapid in its march. This was not the only evidence of danger he found in connection with our milk supplies, but he purposely alluded only to tuberculosis here. Now this infectious milk might be seldom dangerous to adults, but he had no doubt that a very large number of children were

KILLED BY IT EVERY YEAR,

and that adults would be the better for not using it. The danger being admitted, what should he say with regard to the remedy? He could only suggest the directions in which measures would prove efficient. A question of this kind was more in the department of an administrator than of an investigator. (1) The first general measure which could be recommended as being in the hands of the consumer was the boiling of all milk used.

The prejudice against boiled milk was not justified, in his opinion, and he knew families who had not, on his advice, used anything but boiled milk (except with their tea) for the last fourteen years, and had never suffered from the absence of unboiled milk. He knew children, now nine and thirteen years of age, who had never within his knowledge taken any unboiled cow's milk. and had never shown any dislike for boiled milk. The great objection to this remedy was that it did not check the spread of tuberculosis in cattle; it did not protect our cream, butter, and cheese supplies. (2) A second method of dealing with the question was to analyse from time to time samples of milk taken on the market, and condemn unmercifully any milk with dangerous properties. This method was not a practical one. It did not protect the public, for a good reason. It was not easy to detect, by rapid methods, whether a sample of milk was tuberculous or not; and while an examination was being made one hundred people might partake of very dangerous milk. It was actually impossible to examine all the milk reaching a town daily, and there must remain intervals during which the public was not protected. This method was really an investigation method, which had a great use in testing other methods of prevention to see whether they were really effective, but which could not be used as a routine preventive method. (3) We must turn to the actual source of milk—to the cow—and see that it was not allowed to contaminate our milk supply. This meant systematic inspection of cowsheds by competent veterinary surgeons; the use of the tuberculin test, in conjunction with careful inspection of each cow; the separation of tuberculous cows from healthy cows; the fattening of cows in a moderate state of tuberculosis for slaughter; the separation of milk from tuberculous cows, and

ITS STERILISATION BEFORE USE,

the throwing away of all milk from tuberculous udders; the thorough sterilisation of infected sheds before they were used again; the better construction of cowsheds, to make cleaning, lighting, and ventilation more perfect, without going beyond what was absolutely necessary. (4) All these measures would have but a temporary effect if no care were taken to prevent the introduction of tuberculous cattle from neighbouring or foreign parts into the county, for he would for the present imagine that they were dealing with the matter as if it were a county question. All cattle brought into the county should be seen and tested by veterinary surgeons appointed by and acting under the direction of some central County Authority. All cattle should be marked and registered, so as to make it possible to detect at once the introduction of cattle, and also to record the tests to which each animal had been submitted. All cattle should be inspected and tested about twice a year, and tuberculous animals weeded out. The breeding of healthy cattle should be encouraged, and provision should be made to keep calves well protected against any chance of infection. (5) Tuberculous persons or animals should be excluded from all dairy farms or dairies. Milk pails, cans, &c, should be kept scrupulously clean, as well as anything coming in contact with the milk. Of the methods he had mentioned two seemed to be of such a nature that they must be controlled by central Authorities—(1) the systematic and periodical inspection of cattle; (2) the testing of all new cattle introduced into a county. The third method was in the hands of the consumer—*i.e.*, the boiling of milk. If such methods were adopted, it would then be only right to see that whilst our home milk supply was properly supervised, foreign dairy produce was not allowed to flood our market unless good guarantees were obtained that proper measures had been taken to safeguard the consumer.

MEDICAL OFFICERS AND THE INSPECTION OF MEAT.

IMPORTANT LOCAL GOVERNMENT BOARD DECISION.

The Burnley Rural District Council has recently had cause to appeal to the Local Government Board to decide upon the refusal of their Medical Officer of Health, Dr. Dean, to examine a suspected carcase, at the request of the Sanitary Inspector, unless he was paid a fee for so doing. The Sanitary Inspector, Mr. S. Edmondson, tells the story thus:—

"On the 7th inst. a farmer called to say that he had been obliged to kill a cow, and he wished the same inspected, in order that he might dispose of it. Knowing that Dr. Dean had refused to accompany Mr. Halstead, one of our Inspectors, in a previous case, unless he was paid for so doing, I accompanied Mr. Halstead to inspect the carcase in question, which was deposited at a farm in Briercliffe. I found the carcase well and carefully dressed, and hanging in the barn. The condition of the carcase was fairly good, but on examination of the lungs I found evidence of tuberculosis. I thereupon pronounced the flesh as unfit for human food. The farmer being dissatisfied, I offered to take the opinion of the Medical Officer of Health. On informing the Medical Officer he asked if I had seized the carcase. I replied that I had not actually said I would seize this carcase, but I had said it was unfit for human food, and on the farmer's expression of dissatisfaction said I would ask you (Dr. Dean) to inspect it. Dr. Dean replied, 'As you have not seized it, it is not the property of the Council, and I shall want two guineas if I go to examine it. I am not a meat Inspector.' It was then arranged that Mr. Halstead should go to the farm and formally seize the carcase, and if the farmer objected to its destruction it should be brought away and notice given that application would be made to a Justice of the Peace on the following morning for an order to destroy the carcase. The farmer, however, consented to the destruction of the carcase before incurring any further risk."

Subsequently Dr. Dean appeared before the Council, and stated that he was not bound to examine the carcase unless he was paid a fee for so doing, and the Clerk to the Council was directed to inquire whether under Article 18, Section 8, of the Duties of Medical Officers of Health, he was not

bound to inspect and examine the carcase in question without the payment of a fee.

The reply from the Local Government Board was as follows:—

"March 3rd, 1898.

"Sir,—I am directed by the Local Government Board to acknowledge the receipt of your letter of the 9th ultimo, with reference to the refusal of Dr. Dean, the Medical Officer of Health of the Burnley Rural District Council, to examine the carcase of an animal unless he was paid a fee for so doing.

"In reply to your inquiry as to the duty of the Medical Officer of Health in the matter, I am to state that under Article 18 (8) of the Board's General Order of 23rd March, 1891, the Medical Officer of Health is required 'in any case in which it may appear to him to be necessary or advisable, or in which he shall be so directed by the Sanitary Authority, to inspect and examine any . . . carcase . . . exposed for sale or deposited for the purpose of sale or of preparation for sale, and intended for the food of man, which is deemed to be diseased, or unsound, or unwholesome, or unfit for the food of man.'

"It appears from the statement which accompanied your letter that the carcase in question was deposited at a farm, that it had been 'dressed,' and if found satisfactory was intended for human consumption. The Inspector, however, in examination of the lungs, considered that there was evidence of tuberculosis, and he therefore pronounced the flesh to be unfit for human food.

"The owner of the carcase being dissatisfied with this opinion, the Inspector offered to take the opinion of the Medical Officer of Health. The duty of the Inspector on this subject is indicated in Article 19 (7) of the Order referred to. By that article, in case any carcase appears to him 'to be intended for the food of man, and to be unfit for such food, he shall cause the same to be seized, and take such other proceedings as may be necessary in order to have the same dealt with by a Justice; provided that in any case of doubt arising under this clause he shall report the matter to the Medical Officer of Health, with the view of obtaining his advice thereon.'

"The Inspector was therefore acting in accordance with his duty in referring the case to the Medical Officer of Health, and it appears to the Board that it became the duty of the Medical Officer of Health to take such steps as might be necessary to enable him to advise the Inspector on the subject.

"The Board consider that article 18 (8) of their Order does not justify the Medical Officer of Health in arbitrarily refusing to inspect and examine a carcase, but that the option given to him by the article must be exercised after considering all the circumstances of the case.

"On the facts now before the Board, they are disposed to think that there were sufficient grounds for making an inspection and examination, and they are of opinion that the Medical Officer of Health should not have refused to make it.—I am, sir, your obedient servant, A. D. Adrian, Assistant Secretary."

THE DANGERS OF DRUGGED BEER.

Pure beer is verily a case of life and death. Chemically treated and concocted stuff sold as beer is found to produce a species of degeneration of all the organisms, profound and perceptive. Fatty deposits, diminished circulation, conditions of congestion, perversion of functional activities, local inflammation of both the liver and the kidneys, are constantly present. Intellectually a stupor amounting almost to paralysis arrests the reason, changing all the higher faculties into mere animalism, sensual, selfish, sluggish, varied only with paroxysms of anger that are senseless and brutal.

In appearance the drinker of impure beer may be the picture of health, but in reality he is most incapable of resisting disease. A slight injury, a severe cold, or shock to the body or mind will commonly provoke acute diseases, ending fatally.

Compared even with inebriates who use the worst kind of alcohol, he is more incurable, more generally diseased.

The constant use of this chemical-laden beer every day gives the system no recuperation, but steadily lowers the vital forces. It is the direct result of observation that drinking of this adulterated beer in this country produces the very lowest form of inebriety, closely allied to criminal insanity, and it is because of this knowledge that legislation against those beer brewers who are guilty of turning out this poison stuff is a matter of moment.

THE EVILS OF OVER-EATING.

By Dr. Dio Lewis.

Large eaters are generally deficient in activity and endurance. I used to know one who tried hard to be a Christian, but failed because of too much dinner. That man was a curiosity. He worked in a small wood turning shop, and ate five times a day. When he consulted me about his "poor stomach" I told him flatly that he was a pig. He replied, "You are mistaken, I am faint half the time, and have to eat extra meals to keep up my strength." I went at him with fact and physiology. At length he was convinced, and promised me that he would follow my prescription, which was this: Take but two meals a day. . . . In fifteen days his faintness had disappeared and he rapidly recovered. To-day he is a healthy, active man and a warm advocate of two meals a day, and moderate ones.

Temperate people with good digestion never feel their stomachs—forget they have stomachs—while these big eaters are always hungry, faint, or bloated, troubled with eructations, acidity, diarrhœa, or some other unhappy condition of the digestive apparatus.

Persons having a good stomach to begin with can by practice learn to digest an enormous quantity of food. If they give their whole force and vitality to this business of grinding grist, they can, in the course of even a short life, grind through immense quantities. But the wiser, the more human way, is to find out just how much food is needed to run the machine, exactly what fuel will keep the system at the best working point, and never pass these bounds.

For years the author had eaten three hearty meals a day. At length, upon a careful considera-

tion of the physiology of digestion, he thought he was probably using too much of his force in that function. He reduced to two meals a day. He cannot express what freedom of mental and bodily activity he experienced. Men with large heads and well-made bodies sometimes consume so much of their nerve force in digestion that they have nothing left with which to achieve those triumphs that otherwise would be easy to them—*Journal of Hygiene.*

WATERED MILK.

By Joseph H. Geisler, Ph.C., F.C.S.

It is not the purpose of this article to find fault with the cow or with the "town pump" in watering milk, but to explain briefly how the percentage of added water is ascertained, inasmuch as juries, lawyers and judges so frequently find great difficulty in comprehending the data of milk analyses.

Milk analyses commonly state the percentage of water, total solids, fat and the ash. The total solids are the residue left after evaporating all the water, and consist of the fat, caseine, albumen, milk, sugar and ash. The latter is also frequently termed "salts"—saline or mineral matter.

The present New York State law demands that milk shall not contain more than 88 per cent. of water, nor less than 12 per cent. of solids, nor less than 3 per cent. of fat. If the analysis shows the milk to contain more than 88 per cent. of water, or less than 12 per cent. of solids, or less than 3 per cent. of fat, the law deems such milk adulterated. Bearing this in mind, let us take for illustration the results of an analysis of milk which showed:

		Per cent.
Water		89·50
Fat	3·00	
Caseine and albumen	6·88	
Ash	·62	
Total solids		10·50
		10·000

The ash is frequently not estimated. For analysts to calculate the milk as watered in such cases is an unwarranted and questionable licence. In the absence of evidence to show that the above milk has been skimmed, the data would indicate that the milk had been watered at least 14·2 per cent.

Since the law admits the possibility of 88 per cent. of water in pure milk, and the analysis disclosed the presence of a total of only 89·50 per cent. of water, it generally puzzles the uninitiated how it is possible to state that the milk had been watered 14·2 per cent., as the excess over the limit set by law is only 1·5 per cent. Whence the extra 12 7 per cent. ?

The simple rule for calculating the adulteration takes for its basis the minimum limit of solids adopted by law, namely, 12·00 per cent., and may be briefly stated as:

$$\frac{100\ (A-B)}{B} = X$$

in which A represents the percentage of solids in pure milk as defined by law; B the solids found by analysis; X the percentage of water added to the original milk. It must be evident that the addition of water dilutes the total solids and thereby lessens the percentage of the same. To make this clear and at the same time make the above rule more comprehensible, I will present the following practical illustration:

Leaving out of consideration the slight difference in specific gravity between water and milk, let us take 100 lb. of milk of minimum quality (namely, 88 per cent. water and 12 per cent. solids) as the basis for adulteration, and add to it an *equal volume* of water, say 100 lb. It is evident that the milk has been adulterated 100 per cent. The original milk having the composition 88 per cent. of water and 12 per cent. solids contained: 88 lb. of water and twelve lb. of solids.

A chemist analysing the adulterated milk (*i.e.*, after the addition of the 100 lb. of water to the original milk) would find and report the mixture to contain—

	Per cent.
Water	94
Solids	6
	100

with the statement that the original milk had been adulterated by the addition of 100 per cent. of water. The reason for this is apparent. The 100 lb. of original milk contained 88 lb. of water and 12 lb. of solids, to which were added 100 lb. of water, making a total of 200 lb. of mixed or adulterated milk. The mixture therefore consists of 188 lb. of water and 12 lb. of solids. In other words, the solids have been diffused through 200 lb. of mixture. This, reduced to simple percentages (or parts per hundred), necessarily makes the following exhibit:

	lb.		Per cent.
Water in original milk ...	88	= 44 lb. water	
Water added	100	= 50 lb. water	... = 94
Solids in original milk ...	12	= 6 lb. solids	... = 6
Total mixture... ...	200	= 100 lb.	100

Div. by 2

Consequently, the 94 per cent. of water as stated in the analysis, showing an excess of 6 per cent. over the maximum amount allowed by law, viz., 88 per cent., does not indicate a mere excess of 6 per cent. of water, but an actual addition of 100 per cent. of water to the original milk. Sight is lost of the fact that in the adulterated sample the "88 per cent." is not exclusively water of the original milk, but in part some of the added water as clearly shown above.

Addition of water, as above stated, simply dilutes the solids and distributes them through the mixture. The larger the addition of water the greater the dilution of solids, so that the addition of water and loss or diminution of percentage of solids bear a definite ratio to each other. For this reason the solids are taken as a basis of the calculation for estimating the percentage of added water.

Referring to the first analysis above and making the necessary substitutions in the formula—

$$\frac{100\ (A-B)}{B}, \text{ we have: } \frac{100\ (12-10{\cdot}5}{10{\cdot}5}$$

$$= \frac{100 \times 1{\cdot}5}{10{\cdot}5} = 14{\cdot}2 \text{ per cent.}$$

Hence the excess of 1·5 per cent. of water (89·5—88·0=1·5 per cent.) represents an actual adulteration of 14·2 per cent.

Although the calculation is simple, it is nevertheless a fact that the interpretation of the data of

milk analysis is wofully misunderstood. Chemists frequently err in calculating milk deficient in solids as having been watered. As a matter of fact, in the absence of the percentage of ash, chemists are not warranted in their calculation of a percentage of adulteration by the addition of water, for the result may have been brought about by the removal of cream or skimming. However, that is a matter not under consideration in this article, the explanation in which I desire to confine to purely watered milk.—*American Grocer.*

ANTISEPTICS IN THE PRESERVATION OF MEAT.

M. Duprez has recently presented a report to the Board of Health of the Seine, Paris, in which he calls attention to the increasing use of antiseptics by butchers for preserving meat. The product most generally used is olobar, which is nothing but a solution of bisulphate of calcium, containing 99 grammes of sulphurous acid to the litre. Riche claims that the use of this compound is daily increasing, and it is now extensively used in beer. It is claimed by the manufacturer of olobar that its use is harmless in that it does not cause the meat to undergo any appreciable change. This, however, hardly seems probable when we consider that we submit our staple food stuffs to the influence of agents as active as sulphurous acid and the sulphites; neither does it seem tenable that their action would be limited to the initial products of fermentation so as to absorb them and counteract their efforts. Experiments have demonstrated that a 1 to 8 solution of calcium bisulphite will penetrate very deeply the meat soaked in it, and that the normal structure and muscular fibre does not remain the same, hence the refrigerating process alone should be relied upon for the preservation of meats.

DIET OF PROSPECTIVE MOTHERS.

This subject of diet is very often brought to the attention of the physician. Without doubt, some of the discomforts of pregnancy and child-bearing are greatly aggravated by improper diet. The following suggestions are translated from a French journal:—

An excess of water and albuminous food should be avoided—water, on account of its tendency to produce hydroamnion, and albumen, because it favours excessive growth of the child.

The following is the diet prescribed, which has been tried in a number of cases:—

Meat once a day, green vegetables and potatoes, avoid eggs, peas, and beans, as they are too rich in albumen. The advantages claimed for this regimen are:—

(1) The patients are active until the eve of their accouchement; they do not suffer from a sensation of fulness, excessive formation of fat, thirst, or constipation.

(2) Rapid and easy delivery, even in those cases in which the previous labours have been prolonged and difficult.

(3) There is never an excess of liquor amnii.

(4) All the women thus dieted have nursed their babies. The quality and quantity of the milk were always good. The children were very small, but healthy and well formed. They averaged about 6 lb. in weight.

DIET FOR CONSUMPTIVES.

Next to fresh air, diet plays the most important part in the prevention and cure of consumption. It should be highly nutritious and very digestible.

All stimulants should be avoided unless specially ordered by the attending physician, and then only in the exact quantities and at the times specified by him.

THE QUANTITY OF FOOD

is important. Consumption is a wasting disease, and the waste must be more than repaired to get improvement. The patient *must* take, every twenty-four hours, at least two quarts of milk, three eggs, three-quarters of a pound of beef or mutton, and twelve ounces of bread made from the entire wheat. This daily quantity of these foods should be taken as long as they do not produce distaste or disturbances of the stomach or bowels, in which event the suggestions for deviation should come from the physician. In addition to the above, which the patient *must* take, he *may* select whatever suits his fancy from the following:

ARTICLES OF DIET PERMITTED.

Soups. — Oyster, turtle, tomato, mutton or chicken broth. Particularly the jelly and gravy made from meat.

Fish.—All kinds of *fresh* fish and oysters, either broiled, boiled, stewed or baked.

Meats, Bread, &c.—Broiled or roasted mutton or beef, *rare;* steaks; chops, poultry game, sweetbreads, brain, stewed tripe, gelatine, cream cheese, whole wheat bread

Eggs.—Raw, poached or boiled. Raw, beaten in milk.

Vegetables.—Celery, cauliflower, watercress, greens, peas, spinach, beans, tomatoes.

Fruits and Nuts.—Bananas, pears, peaches, plums, apricots, grapes, nectarines, oranges, figs, dates, baked apples—*all without sugar.* English walnuts, almonds, filberts, roasted or boiled chestnuts.

Drinks.—Water, hot water, carbonated waters, milk, boiled milk with or without vichy; cream, koumiss, peptonized milk, cocoa or tea, *without sugar.*

ARTICLES TO BE AVOIDED.

All fried food, veal, pork, sugar, pies, pastry, puddings, salt or smoked meat or fish, macaroni, spraghetti, potatoes, turnips, carrots, parsnips, beets, arrowroot, sago, corn starch, tapioca, hominy, rice, wheat bread, rye bread, iced drinks, ice cream.

If an article of diet cannot be found in either of the above lists, the patient should not decide upon its classification, but should ask his physician to do so.

The following rules should also be observed:—Eat slowly and chew the food thoroughly. Do not take liquids during or shortly after meals. Milk should be taken in sips, and at least ten minutes occupied in drinking a tumblerful. In cases of faulty digestion, take food at regular intervals, frequently, and in small quantities.

HARMFUL EFFECTS OF TEA DRINKING.

Dr. James Wood, an American physician, has published a report on observations regarding the bad effects of tea-drinking. He states that out of 1000 patients applying for treatment at the Brooklyn Central Dispensary, 100 exhibited symptoms pertaining directly to tea-drunkenness, while many others were doubtless suffering more or less from it. The effects of tea, according to Dr. Wood, differ somewhat according to the kind taken, as he finds that the tea of India contains two and one-half times as much tannin as that of China. The headache so frequently suffered by tea tasters, he attributes to the essential oil, of which the tea contains three-fourths of one per cent. Tea tasters drink the infusion immediately after it is made. Dr. Wood notices a great difference in susceptibility to tea-poisoning. He says, "Some people are profoundly intoxicated by indulging in two cups of strong tea per day. . . . We find that an ounce of tea-leaves used daily will soon produce poisonous symptoms. This amount will contain six grains of theine." Of the one hundred cases of tea-poisoning mentioned by the author, sixty-nine were women, and thirty-one were men. Fifty-four drank two pints or less; thirty-seven, four pints or less; and nine, ten pints or less. The following symptoms were present in nearly all cases of tea intoxication: Hallucinations, nightmares, successive dreams, obstinate neuralgia, anxiety, a persistent sinking sensation in the epigastrium, prostration and general weakness, excitement, and mental depression. According to Dr. Wood, tea-poisoning is responsible for half of the headaches, and a large proportion of all cases of despondency, palpitation of the heart, giddiness and allied symptoms. The essential oil of tea which gives out its peculiar aroma, is, according to Dr. Wood, a powerful poison. Its injurious effects are so well recognised by the natives of China that they do not use tea until it is a year old, thus allowing this deleterious substance to escape. Green tea contains more of the essential oil than black tea, which accounts for the fact that it is more productive of nervousness.

THE DIET OF DYSPEPTICS.

How shall we treat dyspeptics? Medicaments are not of much value, or play only a subordinate part. The main factor lies in proper nourishment. These patients, who have abstained from most kinds of food for years, must now learn anew to eat. Their stomach and intestines very quickly adapt themselves to this new condition. First and above all, it is of importance to increase the quantity of nourishment; secondly, to provide a sufficient variety of foods.

In order to improve nutrition, two articles of food, which hitherto have been often avoided by laymen as well as physicians, play an important part, to wit, bread and butter. Bread forms one-third of the total amount of ingested food in health, and besides having nutritive value, serves the purpose of increasing the flow of saliva during its mastication. It also creates an appetite for other food.

Butter not only improves the taste of various kinds of foods, but is also in itself a nutriment of the greatest importance. The great number of calories which butter contains (100 grammes give 837 heat units, while the same amount of bread developes about 217) shows this in the clearest manner. Another advantage which butter presents is that its volume is only about one-third that of bread. A patient taking about one-quarter of a pound of butter a day receives therewith more than one-half of the heat units required. This quantity of butter is well borne by most of the patients.

As nutrition plays the principal part in the treatment of these patients, it will not be amiss to give a few hints with regard to its management. To begin with, it does not appear advisable to permit patients who have abstained for a long while from the coarser varieties of food everything at once. This abrupt change may at times be the cause of various unpleasant symptoms; therefore it should be accomplished gradually. At first give, besides milk, gruels and thickened soups, eggs beaten up in milk, &c. A few days later begin to add to this bill of fare biscuits with butter; then permit meat, the white of chicken, and well-done beef; next, mashed potatoes; still later give wheaten bread, baked or boiled potatoes, soft-boiled eggs, oysters; at last allow vegetables and fruits.

An essential point with regard to nutrition is punctuality in the taking of meals. In most of these cases, in which a gain in weight is of great importance, frequent meals (five or six daily) will be advisable. Although it does not appear advantageous to prescribe for the patient the quantities of the various foods in exact weight (grammes or ounces)—as by so doing they are too easily reminded of their ability or inability to digest this or that quantity and not more—it is nevertheless of value to mention approximate figures by which they may be guided or below which they shall not go.

Thus, for example, they may be told to eat as much as their neighbours at table, or that they shall take ten ounces of milk at this or that meal; or, as I frequently advise, that they shall consume one-quarter of a pound of butter a day. Emphasise those points which appear to be the most important, and leave the patient great liberty in all other particulars. We must strive to familiarise the patient with the idea that ample nourishment will strengthen his organs (including the stomach and intestines), and we must always endeavour to dispel the fear of food with which he is harassed.

Dangerous Cigarettes.—Cigarettes with gilt or silvered ends have become of late fashionable. It is reported that some of these which have been examined have been "gilded" with an imitation of gold attached to the paper by lead chromate; and the silver of others is of a like quality, attached by white lead. As the ends which are ornamented are intended to be placed between the lips, such cigarettes are of course highly dangerous to health.

HAY'S FOODS.

HAY'S FRUMENTINE.

TO YOUTHS, ADULTS, and to all who wish to excel in athletic exercises, such as CYCLING, BOATING, CRICKET, FOOTBALL, &c. &c. Try, either in the form of Porridge, or as a thickening for SOUPS, GRAVIES, &c. &c., the delicious and invigorating qualities of HAY'S FRUMENTINE.

HAY'S INFANTS' FOOD

TO EXPECTANT MOTHERS.

It is of the highest importance that, in order to lay the foundation of a vigorous, mental, and bodily constitution in after life the infant should during its Ante-Natal Existence receive the best and most beneficial maternal impressions. The attainment of this desirable object will, therefore, best be accomplished by attention to your own health, moderate exercise, cheerful society proper care of the digestive organs, and by adopting a Porridge diet of HAY'S delicious and LIFE-IMPARTING FRUMENTINE.

HAY'S FRUMENTINE.

TO NURSING MOTHERS who can bring up their children in the natural way,

USE HAY'S FRUMENTINE,

which imparts Life, Stamina, and Nourishment of priceless value to both mother and infant.

PRICE 6D., IN 2 LB. PACKETS.

HAY'S INFANTS' FOOD

TO THOSE MOTHERS less favourably constituted and who desire to feed their Infants on a bone, muscle, and brain-forming Food that will produce A VIGOROUS GROWTH OF THE BODY GIVEN THEM

HAY'S INFANTS' FOOD,

In Tins, price 8d. and 1s. 3d each.

HIGHEST TESTIMONIALS From all the Medical Journals.

HAY'S FRUMENTINE.

HAY'S HYGEIAN FLOUR MILLS AND FOOD WORKS, HULL, AND

WM. HAY, Limited, Manufacturing Chemists, HULL.

UNRIVALLED AND UNSURPASSED

THE PIONEER MALT EXTRACT.

PRESCRIBED IN DYSPEPSIA, ANÆMIA, WASTING, BILIOUS, AND NERVOUS DISEASES.

M. HOFF'S LONDON HOUSE: Leopold Hoff 29 New Bridge St. London E.C.

COMALTANA WINE

The most NOURISHING & INVIGORATING Wine ever introduced.

COMALTANA is prepared carefully and scientifically from, amongst other ingredients, Coca Leaf, Extract of Malt, and well-matured Port Wine.

Invalids and those suffering from Mental and Bodily Exhaustion find it invaluable.

It is popular among athletes. Gives strength and tone to the system. Lady cyclists especially find it invigorating and a preventive of fatigue.

Price 3s. per Large Bottle.

Sold by Chemists, Wine Merchants, and Stores.

PREPARED ONLY BY THE

COMALTANA WINE CO., Heckmondwike

Sample Bottle sent free to Medical Men on application.

HUBBARD'S 50 Years' Reputation

Light, Nourishing, and Attractive

BY ROYAL WARRANT TO HIS MAJESTY THE KING OF ITALY

SCOTCH RUSKS.

Invaluable to Infants and Invalids.

SUPPLEMENT TO

THE SANITARY RECORD.

No. 17. JUNE, 1898.

FOODSTUFFS UNDER SCRUTINY.

WHAT TO EAT AND DRINK, AND WHAT TO AVOID.

"SANITARY RECORD" ANALYSES.

IMPORTANT ANNOUNCEMENT.

OWING to the growing popularity of this feature of our "Food and Health" Supplement, we have found it necessary to make arrangements whereby, in future, much fuller reports will be given of proprietary articles than have appeared hitherto. It has been our custom to solicit samples of articles for investigation from the manufacturers direct, unconditionally; but in future such samples as we receive from the proprietors thereof will require to be accompanied by a declaration that the sample is selected from stock, and not put up for the special purpose of analysis. Failing this we shall make the purchases ourselves, selecting the articles at random from the various retail establishments where they are sold.

We have retained the services of Mr. C. G. Moor, M.A., to examine and report on the various substances submitted to us.

All such analyses may of course be quoted as having appeared in THE SANITARY RECORD, but the date must be given, and Mr. Moor's name must not be quoted for advertising purposes without special permission.

Edwards' Humanised Condensed Milk.

Prepared by HENRY EDWARDS, The Creamery, Tutbury.

THIS preparation is designed to provide a condensed milk at a price within the reach of all, which shall, when simply diluted with water, produce a liquid having the same chemical composition as human milk. The ordinary sweetened condensed milks are overloaded with sugar, and the unsweetened condensed milks, though more suitable for feeding young children on, contain a proportion of albumenoids to fat which is considerably higher than is the case with human milk.

The sample yielded on analysis the following figures:—

Fat	13·5
Nitrogenous matter...	7·0
Milk sugar...	21·2
Mineral matter...	2·0
Water	56·0

When diluted with three parts of water, according to the directions, it will clearly produce the closest possible imitation of average healthy human milk, and should prove of great value not only to young children but also to invalids.

THE HEALTHFULNESS OF MILK.

To be suspicious of the purity of our supply of milk is to have our peace of mind completely destroyed. Milk is the food for our tender infants, and it enters into the majority of our prepared foods which we estimate mostly as luxuries. We have been much disturbed of late years by the discoveries made in regard to the many and serious risks we run in this respect. Nothing else has so disturbed the public. It has been charged that the very large number of deaths among infants is due to impure milk, and the most deadly of the diseases by which both young and old are affected have been laid at the door of the dairyman. This is a very serious matter, if it is all truth. But while there is unquestionably good reason to be disturbed on this account, we must not be misled by the perhaps too common habit of exaggeration of whatever may be made a source of excitement by some of those writers who delight in making a sensation. The fact is that there is nothing in all that has been said and written of late in this respect that has not been existing for many years. Indeed, those who have the means of knowing these things are very sure that the public health is far better preserved now than it has ever been before, and that the death-rate is steadily decreasing. But while this is so it gives no good reason why we should not still further improve in this respect, and taking all that is said and written on the subject seriously to heart, make every attempt to conform in our dairy practice to all the modern improvements in regard to sanitary conditions.

The recent discoveries in regard to the behaviour of the uncountable numbers of injurious organisms which are to be found in all decomposing matters have given us altogether new ideas in regard to the importance of the most thorough cleanliness in the work of the dairy. But it is no small thing to contemplate. It covers everything. There is

nothing, however small it may appear to us, which is not mixed up more or less in this study of what it is to be clean in our dairy work. One may think that it is sufficient to avoid the dropping of the filth from cows into the pail by carefully brushing them before the milk is drawn. But this is only a small part of it. The source of impurity may be in the cow, derived from her food, or the water she drinks. It may be in the air she breathes, or in her condition of health disturbed by some inconspicuous accident in her management. It may lurk in some corner of some utensil, or in the water in which these have been washed. It may even be in the person who is milking the cows, existing in his clothing and brought unknowingly from some quite unthought-of source. Indeed, we believe that the large majority of cases of sickness or deaths due to infection of the milk by germs of disease are thus originated. So that it is a very deep and broad subject to study, and a matter for more than a casual thought, how milk may be preserved in the strictest purity, and its healthfulness certainly assured.

It is quite certain, however, that the chief and most frequent source of infection of milk with unwholesome germs is the water in which the utensils are washed. We are not to think, however, that infection of milk is anything like nearly so frequent as is sometimes alleged. It is, we believe from a constant watch upon the matter in every possible direction, a rare thing to happen, but when it does occur the consequences are exceedingly disastrous. Instances have happened in which fifty, and even more than a hundred deaths, have been clearly traced to the infection of milk with the germs of typhoid fever through the water used in the way mentioned. And we all know how it is at this season, when the accumulation of waste matter on the ground through the winter is very apt to be washed into springs and streams by the melting snow, or the overflowing of the surface by the spring rains. So, too, we may easily suspect a great number of wells in which surface drainage may flow and carry with it the accumulated filth gathered during the winter. Doubtless much of the sickness that comes with the spring and early summer may be thus caused, and it should be seriously thought of by all concerned.

Water is a general solvent, and this fact is not thought of as it should be. We think much more of impure air, but this is not nearly so serious a matter as impure water. Water is absorbed directly into the blood, and all its impurities, of course, thus go to the very fountain of life. Water is not filtered of its impurities as the air is. When air is breathed it passes through the nostrils which are almost moist and covered with an adhesive mucus, by which in many cases the injurious germs are arrested, and discharged with the infected matter. So that impure air is quite innocent in comparison with impure water, and whether this goes into the cow or infects the dairy utensils, it has the same result, the infection of the milk.

Impure air is the next in importance of the various dangers to milk. This is absorbed by the cow and infests the blood, and, of course, the milk. It is filled with noxious germs which settle on the milk as it is drawn into the pail, and as the milk may stand in a filthy stable. A case is reported in which cheese made from milk infected by the odours from a dead animal in a field at some distance from the cow stable was quite unfit for use, and if such was the result it would have been much worse for the butter made from such infected milk. Dust from mouldy hay has been shown by experiment to spoil milk for butter making; at times wholly preventing the churning by the foaming and slimy condition of the cream. The same impurity has been detected as the cause of floating curds in the cheese vat, and it is by no means an uncommon occurrence. Mouldy litter under the cows has had the same result by the action of the special germ of the mould on the milk. In short, every kind of impurity that may be existing in the cow, or its surroundings, may be traced all through the milk and its products, and its behaviour in making these, as clearly as one's footsteps may be traced in the winter's snow.

POISONED SHELL FISH.

Mr. E. B. Reece, coroner, held an inquest at the Town Hall, Cardiff, on the 7th inst., on the body of a child named Beatrice Maud Hicks, the seven-year-old daughter of George J. Hicks, an engineman, living at 35, Llantrisant-street, Cathays, Cardiff, who died under painful and mysterious circumstances on the morning of the 4th inst. It appears that the inquest was held at the instance of Dr. Sheppard in consequence of the death of Beatrice's little sister, who died on Wednesday morning earlier in the same week. The doctor had certified the death of the first child, as, although no cause could be found to account for the fatal issue of her illness, the case seemed simple, and it was only upon the death of the second child, under similar circumstances, that it was deemed necessary to hold an inquiry. The story told by the father, George Hicks, was that on Whit-Monday the two children were playing in a field off Llantrisant-street, when they picked up and ate some periwinkles, which were in a decayed state. They were seen to do this by another little girl, named Joyce. She, being a little older than the other children, told them not to eat them as they were stinking badly, but, unfortunately, they had swallowed a good many. In the evening the children returned home and went to bed. On Tuesday morning Sarah Ann seemed very ill, and her sister Beatrice, who slept with her, said that during the night she had been restless, and seemed very unwell, and had been vomiting. The father immediately went for Dr. Sheppard, who on arriving found that the child was both feverish and delirious, and suffering from acute peritonitis. He saw the child several times, and she grew gradually worse and worse, and died at 1.30 on Wednesday morning. The doctor certified the death as being due to peritonitis. The funeral was fixed for Friday, when the second child, Beatrice, on whom the inquest was now held, became very ill. Dr. Sheppard was again called, and he found the second child suffering in every way the same as the first had, except that she was not delirious. She died on Saturday morning. The doctor was stating his intention to have an inquest held, and debating with the father as to whether or not a *post-mortem* should take place, when the mother sent for them, saying that she had heard from Joyce about the children eating periwinkles.

The mother then went into the box, and in every way corroborated the father's tale, adding, however, that rumour seemed to point to the fact that a man had been seen selling periwinkles in a field near, and that, as he had not been able to get rid of them all, he had thrown some away.

The little girl Joyce then described seeing the two deceased children eating the periwinkles, and telling them to throw them away. She, too, had heard of a man being seen selling periwinkles in the neighbourhood.

Dr. Sheppard corroborated the story of the father as to being called to the child, Sarah Ann Laura, on Tuesday morning. She was undoubtedly suffering from acute peritonitis, or inflammation of the intestines, and he saw from the first that the case was hopeless. He was much surprised when called in to the second child, Beatrice. He saw no hope of her recovery either. In both children the symptoms were most marked, and he considered the circumstances pointed towards poison. When he heard about the periwinkles he had not the slightest doubt that they were the cause of the trouble, and that the children died from ptomaine poisoning. He had not made a *post-mortem*. Decayed periwinkles would certainly bring about such an illness.

The Coroner, in summing up, said the case was most painful and serious. If a man had been really selling decayed periwinkles and had thrown them away he could, doubtless, be prosecuted. The police had made a number of inquiries, but had failed to get at anything definite.

The jury, without hesitation, returned a verdict in accordance with the medical evidence—that the children died from ptomaine poisoning, consequent upon eating decayed periwinkles.

MEAT INSPECTION ON THE CONTINENT.

It is well known that sanitary legislation, especially in regard to foodstuffs, is more advanced in continental countries than it is here.

In Belgium, one of the nearest and most enlightened, a complete system of meat inspection was instituted in 1890. One of the regulations states: "The Government is authorised to regulate and supervise the trade in foodstuffs, and substances for the food of man and animals, but only from the point of view of public health, or with the object of preventing imposture and adulteration.

"It can further, but only in interests of public health—. . . As regards butcher's meat especially, it must not be exposed for sale or sold unless it has been recognised as fit for food after an expert examination. If fresh meat is in question, this expert examination must take account of the condition of the internal organs."

Regulations are also made, and definite instructions given, regarding the inspection of meat imported from abroad.

Most of the continental countries proceed on somewhat similar lines with different variations, and surely we ought not to be behind in protecting the public so far as possible from being imposed on with unwholesome or diseased meat. In Prussia the regulation states: "All animals must be examined before and after slaughter by a veterinary surgeon, or by an Inspector. The latter, however, can only pass judgment in certain definite conditions (which are elsewhere specified), and must call in a veterinary surgeon whenever there is the least doubt." "No animal may be slaughtered or cut up without the approval of the Inspector, and only such parts of the carcase may be used for food as are passed by him. In the case of fresh meat introduced from without, a certificate must accompany it, showing that it has been inspected by an expert." And in Norway—"In every commune where the above laws are in force, all fresh meat exposed for sale for human consumption must be examined by the Municipal Inspector and stamped." The laws referred to are in connection with the establishment of public slaughter-houses.

ADULTERATION OF MILK.

IMPORTANT DECISIONS.

The Farmer Co-operative Association, Limited, of Plough-yard, Shoreditch, was summoned by the Sanitary Authority of St. Leonard, Shoreditch, for supplying to the Holborn Union Workhouse, City-road, milk not of the nature and quality demanded.

Mr. Robinson, Vestry Clerk, supported the summons, Mr. W. T. Ricketts, solicitor, defending.

The case for the prosecution was that the milk supplied under contract to the workhouse not being satisfactory, samples were taken from the four churns, thirty-four gallons, delivered on the morning of the 13th ult., and in three cases the contents found to be adulterated with water.

Mr. Ricketts, for the defence, put in four contracts from farmers supplying the particular milk, and these contracts being read, showed that the company contracted at 1s. per gallon for milk, "pure and with all its cream, not less than 10 per cent." He submitted that these contracts under the decision of "The Farmers and Cleveland Dairy Company *v.* Stevenson" exonerated the defendants, and called evidence to prove that the milk was not tampered with, but was sold as received at Liverpool-street Station.

Mr. Corser dismissed the summons against the company, and said he would grant summonses against the farmers, if the Vestry Clerk had satisfied himself who was responsible.

THE PURE BEER QUESTION.

BARLEY-MALT SUBSTITUTES.

The best of all beers is brewed in Bavaria. It is there made an illegal act to brew from anything but barley-malt and hops. The beer is so pure and palatable that the Bavarians drink every gallon that is brewed, although the quantity is something very considerable. A great quantity of beer is both brewed and consumed in Great Britain; but, inasmuch as British brewers are permitted "to use any wholesome materials" for the purpose of their trade, it follows, perhaps naturally, that numbers of them prefer to brew from those materials which come cheapest. Those who have

followed the labours of the Beer Materials Committee have been able to form some sort of idea of the extent to which these cheaper substitutes are employed.

POTATO-GLUCOSE, MAIZE, INVERT SUGAR, AND RICE

are used in enormous quantities. It cannot, perhaps, be alleged that any one of these articles is other than "wholesome." There is no reason why brewers should not employ any or all of them in the manufacture of beer. But there is abundant reason for urging that every brewer should be compelled to declare the nature of the beer he brews and sells. Mr. Charles E. Cassal, F.I.C., secretary of the Society of Public Analysts, in his evidence before the Committee, expressed the opinion that brewers who use these cheaper substitutes for barley-malt directly contravene the principles of the Food and Drugs Act, and should therefore be compelled to declare the nature of the liquor they brew. He said of beer, concocted of potato-glucose, invert sugar, maize, rice, or other materials than barley-malt and hops, cannot be of "the nature, substance, and quality" of beer, any more than an admixture of margarine and butter can be held to be of "the nature, substance, and quality" of butter. The one is as much a case of adulteration as the other, he maintains. "Beer" is a term which, by long usage, has become associated with a drink brewed from barley-malt and hops. Parliament has dealt loosely with its legislative enactments in regard to food adulteration.

NO LEGAL DEFINITION OF "BEER."

Any kind of drink may be called and sold as beer, and all kinds of slop are palmed off upon the unwary under that generic term. There are British firms claiming to brew only from barley and hops; but even some of these have been discovered in the act of brewing from cheap foreign barley where they represented themselves as brewing from British barley. The term "beer" needs to be more strictly defined. The most convenient course would be to make it stand for a liquor brewed only from barley-malt and hops. The average man who purchases beer expects to be supplied with a liquor so composed. Oftener than not he pays for an article which is not what he expects it to be. It may be potato squash or sugared water merely. The brewer who sells these concoctions as "beer" is morally guilty of fraud. It may be that some of these compounds are as strength-imparting as barley and hop beer. Some people allege that margarine is equal to butter as a food. But the provision dealer who sells margarine as butter is liable to conviction for raud; and

THE LAW OUGHT TO BE SO AMENDED

as to make it illegal to sell cheaply-brewed drinks as beer, when, in the popular sense of the term, they are nothing of the kind. Let it be owned at once that this is not written in the interest of the British barley grower. But does it not also serve the interests of the beer consumer? He pays for his beer the price for which a sound barley and hop beer may be provided; and too often he gets drink which is not worth one-half its cost.

THE DETECTION OF ANNATTO IN MILK.

Milk is often coloured with a trace of annatto to give it a fictitious appearance of richness. To detect this addition, A. Leys employs the following test:—Fifty cubic centimetres of the sample are shaken out with twice the volume of ether-alcoholic mixture composed of alcohol (93 per cent.) 40·8 c.c., ether 54·4 c.c., water 3·4 c.c. Solution of ammonia (sp. gr. 920) 1·4 c.c. After separation, the ethereal layer is rejected, the colouring matter being retained in the aqueous portion. This is transferred to another vessel and half its volume of a 10 per cent. solution of sodium sulphate gradually added, which causes the slow separation of the casein. The clear aqueous portion is decanted and shaken out with amylic alcohol, the washing being conducted in test tubes to facilitate the separation of the solvent. After shaking, these tubes are plunged into a cold water bath, the temperature of which is gradually raised to 80 deg. Cent., when separation will be complete. The amylic alcoholic solution is collected and evaporated. The deep yellow residue is re-dissolved in warm water containing a little ammonia and alcohol, a strip of bleached cotton is immersed in the solution, and the whole evaporated to dryness. The cotton, which is now of a yellow tint, is washed and plunged into a solution of citric acid. If the colouring be annatto, the thread will at once assume a marked rose tint. Uncoloured normal milk imparts a very light yellow tint to cotton by this method, but does not give the change of tint with citric acid, which is characteristic of annatto.—*Journ. Pharm.* (6), vii., 287.

POISONED BY MUSHROOMS.

Dr. George Danford Thomas held an inquest at the St. Pancras Coroner's Court with reference to the death of Arthur Hicks, forty-three, carpet planner, Leighton-road, Kentish Town. The widow stated that on Sunday week her husband cooked and ate some mushrooms, which he had purchased on the previous night at a neighbouring greengrocer's. Soon after eating them he complained of having a very hot taste in his mouth and severe pains in his stomach. Witness, who also ate some, had a hot taste in the throat, but her husband became worse. On the following morning Dr. Fountain was called in to attend to him, but he died on Thursday. Dr. Owen Fountain, Camden-road, stated that he found Hicks suffering from inflammation of the bowels. He afterwards saw, at the greengrocer's shop, a specimen of the mushrooms. They were of the kind known as horse-mushrooms, which, in his opinion were certainly not fit for anyone to eat. He was informed at the shop that they had been brought from Kent. They had a pink colour, but by keeping that would become dark, and be mistaken for the colour of cultivated mushrooms. The effect of eating them would be to cause irritation and inflammation, and ultimately death. The jury returned a verdict of death from misadventure.

THE INSPECTION OF MEATS FOR ANIMAL PARASITES.

A COPIOUSLY-ILLUSTRATED treatise of high practical value has been prepared by the Bureau of Animal Industry of the United States Department of Agriculture, under the direction of Dr. Salmon, Chief of the Bureau. It deals primarily with the parasitic entozoa that infest the bodies of animals —cattle sheep, swine—used for food by man; and, in the second place, it is competent to serve as a guide to stock-breeders and to those who are engaged in the prosecution of sanitary work. The main portion of the volume relates to the flukes and tapeworms of cattle, sheep, and swine, with special reference to the inspection of meats. The more important facts relating to the flukes and tapeworms which Inspectors are likely to find in abattoirs and slaughter-houses are here passed under review. Since certain bladder-worms—such as the beef measle, *Cysticercus bovis*, and the pork measle, *Cysticercus cellulosæ*—are directly transmissible to man through the use of meat, a knowledge of these parasites should enable Inspectors to prevent the spread of the tapeworm stage of these organisms among human beings by condemning the infested meat, or by subjecting it to processes that would render it harmless. The rigid system of meat inspection pursued in Germany has resulted in an actual decrease of tapeworm disease in man and of the frequency of *Cysticercus cellulosæ* in the human eye. Condemnation and destruction of organs infested with certain other parasites—the hydatid *Echinococcus*, the gid bladder-worm, *Cœnurus*, and the long-necked bladder-worm, *Cysticercus tenuicollis*—would prevent the spread of these organisms in their alternating tapeworm stage to dogs, and by that means prevent the re-infection of man and of domesticated animals. In this case prevention of tapeworm disease in dogs, though of comparatively little importance so far as the dogs are concerned, becomes vastly important, not only in public hygiene, but also from an economic point of view in preventing financial losses to stock-raisers from disease and death in their flocks and herds. The destruction of livers heavily infested with fluke would also result indirectly in the diminution of fluke disease in man and live stock. As certain of these animal parasites are capable of bringing about in meat pathological appearances which may at first sight be mistaken for tuberculosis, this furnishes an additional reason for the adequate instruction of Meat Inspectors.

Amongst the general methods for the prevention of parasitic diseases precedence is given to the segregation of slaughter-houses. Every such house is regarded as a centre of infection for the surrounding neighbourhood, not only of diseases caused by animal parasites, but also of such diseases as hog cholera, swine plague, and tuberculosis. By compelling the butchers of a town to do all their slaughtering at one place the risk of spreading disease is minimised. The sanitary supervision of slaughter-houses is next advocated, the work to be entrusted to a competent Veterinary Inspector. In small towns, where the offal is not sufficient in quantity to pay for preparing it as a fertiliser, there would seem to be no valid sanitary objection to feeding the offal of healthy cattle and sheep to swine, but swine offal should never be fed to other pigs until it has first been thoroughly cooked. There should be regular inspection by a qualified veterinarian of all meats before they are allowed to leave the slaughter-house. The rigid exclusion of dogs would prevent the spread of a number of dangerous parasites; rats, again, are active agents in disseminating disease from slaughter-houses. The raising of hogs and other animals at slaughter-houses is a practice which cannot be too severely condemned. The treatment of cattle, sheep, and swine suffering from parasitic worm disease is summed up in two general rules—(1) the treatment for the larval tapeworms and the liver flukes must be preventive, as no known medicinal treatment is satisfactory; (2) the treatment for the adult tapeworms and the intestinal flukes should be medicinal, as this is effective, and the life history of most of these organisms being still problematical, there are no reliable data upon which to base preventive measures.

The disposal of condemned meats is a matter of high practical importance. Destruction by burial or burning is opposed as causing unnecessary loss. The methods favoured are (1) utilisation as fertiliser; (2) rendering the meats harmless by cold storage, cooking, or preserving, and then placing them upon the market; (3) selling the meats under a declaration of their character. As to the first named there is no parasitic disease known which will withstand the temperature used at the large abattoirs in the preparation of fertilisers. With regard to cold storage, experiment shows that such a parasite as *Cysticercus bovis* dies about two or three weeks after the death of its host. Three weeks of cold storage would therefore render a light infection of this kind absolutely harmless, and the meat could safely be placed on the block. In the case of the disease known as pork measles, the parasites live for a month or longer, so that more care would be necessary in dealing with it. Many American abattoirs tank certain meats of inferior quality for the purpose of canning. The heat employed is not so great as that used in tanking for fertilisers, but, as *Cysticercus bovis* cannot survive a temperature of 140 deg. Fah. for five minutes, and as the meats tanked for canning are thoroughly cooked, it is claimed that a light case of beef measles would be rendered perfectly harmless by the cooking preparatory to canning. In the case of trichinosis, again, the parasite cannot withstand a temperature of 158 deg. Fah., so that if trichinous pork is cooked until the whole of it has reached this temperature and acquired a light grey colour, the disease is rendered non-transmissible to man. As regards salting, the parasite of beef measles is killed in twenty-four hours by the action of salt solution, and in no case has the parasite of trichinosis been found to withstand immersion for four months in the pickling vats. In both cases it has to be remembered that some time must elapse before the salt can thoroughly permeate the tissue, and that large pieces of meat require longer immersion than small ones.

Hydatid disease receives special attention in this work, which is undoubtedly the most complete of its kind in the English language, upon the preparation of which, moreover, Dr. C. Wardell Stiles has evidently spared no trouble. Hydatids represent the alternating larval or bladder-worm stage of one of the commonest tapeworms. Up to the present time hydatid disease is comparatively rare

in the United States, and it is hoped that by the exercise of proper precautions at the abattoirs and slaughter-houses the dangerous parasite may be totally eradicated from the country. Unless, however, such steps are speedily taken it is probable that the United States will in time take its place with Iceland, Germany, and Australia in respect to the number of human lives sacrificed to a disease which, so far, has gained little foothold in North America, and can at present be easily controlled. The 124 illustrations, many of them original, are admirable. Among the more striking are those of the liver fluke, the lancet fluke, the human blood fluke, ox-tongue infested with beef measle, the tapeworm of beef measle, pork infested with pork measle, the bladder-worm of pork measle, lamb's liver infested by the marginate tapeworm, sheep's brain infested with gid bladder-worm, and hog's liver infested with *Echinococcus* hydatid.

NUTRITION IN POTATOES.

I. B. Cappoch gives in the *Herald of Health*, his views on the potato. It has the following composition in parts per 100:—

Water	75·77
Albuminoids	1·79
Fat	·16
Carbo-hydrates	21·31
Salts	·97

Here the nutriment may be looked upon as about 23 per cent., consisting of the albuminoids, fat, and carbo-hydrates. The fat and albuminoids are very low, but if served up with milk and cream, these two substances would be increased, and the combination rendered a more perfect food from a scientific point of view.

Those potatoes are the most digestible and nutritious which in boiling break down into a floury mass. This is due to the breaking up of the starch. Young potatoes that do not undergo this process of breaking are in the highest degree indigestible, and should not be eaten by those who are not good starch digesters.

In the preparation of potatoes for the table the following points should be taken notice of:—

The albuminous matter surrounds the skin of the potato, and if the skin is removed one cannot help but remove this albuminous matter at the same time; it follows, therefore, potatoes should be boiled in their skins, which makes it possible to remove them without the albuminous layer underneath. Moreover, the skin acts as a membrane resisting the soaking out of the valuable salts. If potatoes are peeled they should not be allowed to soak in cold water or warm water before boiling, as this helps to dissolve out the soluble salts. Remember that the dissolving out of the salts is reduced to a minimum by baking or steaming the potatoes; both are preferable to boiling.

HANDY BOOKS FOR INSPECTORS for MEMORANDA, OBSERVATIONS, PARTICULARS, &c.—180 pages, 8 × 12½, plain writing paper, ruled feint, bound, paper boards, cloth back, 1s. 9d. each, post free.—Address, The SANITARY PUBLISHING COMPANY, 5, Fetter-lane, London E.C.

Silver Medal, Edinburgh, 1889. Gold Medal, Jamaica, 1891. Gold Medal, Derby, 1891. Highest Award at Chicago Exhibition. Altogether Six Gold Medals received.

COLEMAN'S WINCARNIS

Is a delicious beverage and tonic made from Port Wine, Liebig's Extract of Meat, and Extract of Malt.

WINCARNIS is a name registered to prevent fraudulent imitations.

OVER FIVE THOUSAND

Unsolicited Testimonials have been received from Medical Men.

The following Important Testimonial has been received from Dr. FLETCHER.

Applecross, Rosshire, N.B, July 2nd, 1897.

Dear Sirs,—Please forward quarter-of-a-dozen "Wincarnis" immediately, as my patient's supply is about done.

I trust there will be no delay, as he takes no other nourishment, and has been sustained and gained strength by "Wincarnis" for twelve weeks.—Yours faithfully, Duncan Fletcher, L.R.C.P.

WINCARNIS is sold by all Druggists, Wine Merchants, and Patent Medicine Vendors. Ask for Coleman's "Wincarnis," and see that the word "Wincarnis" is on the shoulder of the bottle. Sold in bottle, 2s. 9d. & 4s. 6d. everywhere.

Sole Proprietors and Manufacturers of the above,

COLEMAN & CO., Ld., Norwich & London

Sample bottle sent free by post on receipt of full postal address.

TRIPLE TEA

IS A PURE TEA,

Being a blend of fine teas from India, China, and Ceylon, and

WE ADVISE YOU TO TRY IT.

It can be obtained direct at the following rates:—

2 lbs. for 3s. 6d.
3 lbs. ,, 5s.
4 lbs. ,, 6s. 8d.
5 lbs. ,, 8s. 4d.
6 lbs. ,, 10s.

HAY'S FOODS.

HAY'S FRUMENTINE.

TO YOUTHS, ADULTS, and to all who wish to excel in athletic exercises, such as CYCLING, BOATING, CRICKET, FOOTBALL, &c. &c. Try, either in the form of Porridge, or as a thickening for SOUPS, GRAVIES, &c. &c., the delicious and invigorating qualities of HAY'S FRUMENTINE.

HAY'S INFANTS' FOOD

TO EXPECTANT MOTHERS.

It is of the highest importance that, in order to lay the foundation of a vigorous, mental, and bodily constitution in after life the infant should during its Ante-Natal Existence receive the best and most beneficial maternal impressions. The attainment of this desirable object will, therefore, best be accomplished by attention to your own health, moderate exercise, cheerful society proper care of the digestive organs, and by adopting a Porridge diet of HAY'S delicious and LIFE-IMPARTING FRUMENTINE.

TO NURSING MOTHERS who can bring up their children in the natural way,

USE HAY'S FRUMENTINE,

which imparts Life, Stamina, and Nourishment of priceless value to both mother and infant.

PRICE 6D., IN 2 LB. PACKETS.

TO THOSE MOTHERS less favourably constituted and who desire to feed their Infants on a bone, muscle, and brain-forming Food that will produce

A VIGOROUS GROWTH OF THE BODY GIVEN THEM

HAY'S INFANTS' FOOD,

In Tins, price 8d. and 1s. 3d each.

HIGHEST TESTIMONIALS From all the Medical Journals.

HAY'S HYGEIAN FLOUR MILLS AND FOOD WORKS, HULL, AND

WM. HAY, Limited, Manufacturing Chemists, HULL.

UNRIVALLED AND UNSURPASSED

THE PIONEER MALT EXTRACT.

PRESCRIBED IN DYSPEPSIA, ANÆMIA, WASTING, BILIOUS, AND NERVOUS, DISEASES.

M. HOFF'S LONDON HOUSE: Leopold Hoff 29 New Bridgest. London E.C.

COMALTANA WINE

The most NOURISHING & INVIGORATING Wine ever introduced.

COMALTANA is prepared carefully and scientifically from, amongst other ingredients, Coca Leaf, Extract of Malt, and well-matured Port Wine.

Invalids and those suffering from Mental and Bodily Exhaustion find it invaluable.

It is popular among athletes. Gives strength and tone to the system. Lady cyclists especially find it invigorating and a preventive of fatigue.

Price 3s. per Large Bottle.

Sold by Chemists, Wine Merchants, and Stores.

PREPARED ONLY BY THE

COMALTANA WINE CO., Heckmondwike

Sample Bottle sent free to Medical Men on application.

HUBBARD'S 50 Years' Reputation

Light, Nourishing, and Attractive

BY ROYAL WARRANT TO HIS MAJESTY THE KING OF ITALY

SCOTCH

Invaluable to Infants and Invalids.

RUSKS.

OF GROCERS, CHEMISTS, AND STORES.

DR TIBBLES Vi-Cocoa

DR TIBBLES Vi-Cocoa

DR TIBBLES Vi-Cocoa

DR TIBBLES Vi-Cocoa

DR TIBBLES Vi-Cocoa

DR TIBBLES Vi-Cocoa

The "LANCET" says:

"Vi-Cocoa must be assigned a place in the front ranks of really valuable foods, since it is the embodiment of all the numerous principles contained in Malt, Hops, Kola and Cocoa . . . of distinct value as a restorative and stimulative food."

The "BRITISH MEDICAL JOURNAL" says:

"Vi-Cocoa is a very palatable beverage of great stimulating and sustaining properties."

The "MEDICAL MAGAZINE" says:

"Medical practitioners will find a valuable weapon in Dr. Tibbles' Vi-Cocoa in combating the various conditions of nervous exhaustion and enfeebled digestion. The ingredients of which it is composed are carefully selected, and of undoubted strength and purity."

The "POPULAR MEDICAL JOURNAL" says:

Dr. Tibbles' Vi-Cocoa is an excellent combination of Kola and Cocoa; and it not only gives the nutritious and sustaining properties, but, having Hops incorporated with it, acts as a tonic and is soothing, while the addition of Malt neutralises all the starchy matter, and so considerably assists weak digestions."

From EDMUND A. ELLIOTT, M.R.C.S., L.R.C.P.

"I have tried Dr. Tibbles' Vi-Cocoa, and my patients are very pleased with it."

From Dr. T. H. SMITH, Royal Colonial Institute, Northumberland Avenue, W.C.

"I have much pleasure in testifying to the superior qualities of your Vi-Cocoa over any similar preparation in the market. I do this willingly and unsolicited, as I consider it a great boon to the public. I have personally experimented with the cocoas in the market, and find that the great drawback to all of them was the slow process of digestion and assimilation. The diastase in the Malt not only assists digestion in your Vi-Cocoa, but it also accelerates the digestion of other foods that are taken with the Vi-Cocoa. This I have personally tested, and can therefore speak from actual experience. Its wonderful recuperative power after exhaustion from fatigue is marvellous."

Merit, and merit alone, is what is claimed for Dr. Tibbles' Vi-Cocoa, and the proprietors are prepared to send to any reader who names this paper (a postcard will do) a dainty sample tin of Dr. Tibbles' Vi-Cocoa free and post paid.

Dr. Tibbles' Vi-Cocoa, 6d., 9d. and 1s. 6d. Can be obtained from all Grocers, Chemists, and Stores, or from Dr. Tibbles' Vi-Cocoa (1898) Ld.), 60, 61 and 62, Bunhill Row, London, E.C.
